THE main thesis of the article on "Adult Education" which appeared in *Nature* of May 7 (p. 783) seems to be that the present weakness of the Workers' Educational Association is largely attributable to the activities of "a few university extra-mural departments [which] found that it was simpler to arrange classes by dispensing altogether with the services of W.E.A. branches". This is not in accordance with the facts. Every extra-mural department, except one, provides classes and courses in co-operation with W.E.A. branches, and the exception (Aberystwyth) has never done so. Some make rather less provision than they did a few years ago; but the reasons for this are not as simple as the article in *Nature* suggests. It is certainly not the case that this change has come about through the deliberate action of any extra-mural department. Although no department would now concede to the W.E.A. the exclusive right of interpreting its university to the people as a whole, departments still look to the W.E.A. to do this among working-people.

There is probably a causal connexion between the recent modest decline in university extra-mural provision through the W.E.A. and the appreciable increase in university extension; but it is very indirect. The rebirth of the latter, which is one of the outstanding features of post-war development in adult education, is due chiefly to the discovery that, for extra-mural work of a certain kind, there is a public which the W.E.A. is unable to reach. This consists of people who have had a good secondary or even a tertiary education, to whom the "education for social purpose" of the W.E.A. makes no appeal. Some members of this public wish for provision which will widen or refresh their professional education; others, whose full-time education was very highly specialized, wish to study (at a level suited to their abilities) subjects which they had to leave aside in their college or university days. It is surely not improper for extra-mural departments to try to satisfy the needs of this public. Yet it would seem to be so according to the article in *Nature*.

University extension designed for its new public is said to be provided directly by extra-mural departments—"laid on" is the term used in the article. If this statement is intended to imply that extra-mural departments normally prepare their extension programmes in the light of coolly calculated market prospects, and then proceed, by high-pressure salesmanship, to sell to the public what they have devised, it is very wide of the mark. Before any programme is drawn up, many interests are consulted—professional, scientific, religious, etc.—and in promoting classes and courses there is the closest co-operation with a great variety of bodies representing prospective students. It is wrong to suggest that provision, other than that through the W.E.A., is devoid of the voluntary principle. The recent growth of extension provision in science, to which Dr. H. D. Turner's article in *Nature* on "Science and Adult Education" (January 22, p. 142) refers, has been due almost entirely to close collaboration between the officers of extra-mural departments and voluntary bodies especially interested in science.

A. J. ALLAWAY

# APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

DEMONSTRATOR IN SOIL SCIENCE—The Registrar, Wye College, near Ashford, Kent (July 26).

ASSISTANT LECTURER IN GEOGRAPHY—The Secretary, University College, Gower Street, London, W.C.1 (July 28).

DEMONSTRATOR IN THE DEPARTMENT OF CHEMISTRY AND BIOCHEMISTRY—The Dean, St. Thomas's Hospital Medical School, London, S.E.1 (July 28).

ASSISTANTS (2) (preferably with an honours degree in bacteriology, or equivalent qualification) IN THE DEPARTMENT OF BACTERIOLOGY, to take part in the lecturing and advisory work of the department—The Secretary, North of Scotland College of Agriculture, 41½ Union Street, Aberdeen (July 29).

DEMONSTRATOR (with a first- or second-class honours degree in chemistry) IN THE DEPARTMENT OF ORGANIC CHEMISTRY; and a RESEARCH ASSISTANT (with at least two or three years experience in postgraduate research work) for work on mold metabolites—The Registrar, The University, Liverpool (July 30).

LECTURER (preferably with some knowledge of statistics) IN MATHEMATICS—Secretary of University Court, The University, Glasgow (July 30).

LECTURER (with a good honours degree in botany or agricultural botany) IN BOTANY—The Secretary, Edinburgh and East of Scotland College of Agriculture, 13 George Square, Edinburgh (July 30).

ASSISTANT LECTURERS IN PHYSICAL CHEMISTRY, and INORGANIC CHEMISTRY—Prof. R. M. Barrer, Imperial College of Science and Technology, London, S.W.7 (August 5).

LECTURERS (2) (with a good honours degree and some teaching experience) IN MATHEMATICS—The Principal, Heriot-Watt College, Edinburgh (August 5).

ANALYTICAL CHEMIST (with a degree, A.R.I.C., or equivalent qualifications) to work on plant biochemistry and, in particular, on pigments—The Secretary, John Innes Horticultural Institution, Bayfordbury, Hertford (August 6).

ASSISTANT DIVISIONAL CHIEF SCIENTIST (with good academic qualifications in chemistry or physics, experience in research, a thorough knowledge of the work of a Scientific Department in the National Coal Board or similar industrial organization, and some experience of administration)—Divisional Chief Scientist, National Coal Board, Northern (N. and C. Division), The Grange, Grange Avenue, Longbenton, Newcastle-upon-Tyne (August 6).

LECTURER OR SENIOR LECTURER (with an honours degree in science or engineering and satisfactory qualifications in physics and mechanics) IN PHYSICS AND MECHANICS, at Britannia R.N. College, Dartmouth—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting 4491-55 (August 6).

RESEARCH ASSISTANT (male or female, with experience in practical microscopy) IN THE DEPARTMENT OF METALLURGY—The Registrar, The University, Manchester (August 8).

RESEARCH ASSISTANT IN THE PHYSICS DEPARTMENT, to help supervise a group of students working on acoustics—The Registrar, King's College, Newcastle-upon-Tyne (August 15).

UNIVERSITY STUDENTS and FELLOWS for research in Experimental or Theoretical Nuclear and Elementary Particle Physics—Professor of Natural Philosophy, The University, Glasgow (August 15).

BACTERIOLOGISTS (2) (graduates in microbiology with postgraduate experience in microbiology or bacteriology) at the ANIMAL RESEARCH STATION, New Zealand Department of Agriculture, Wallaceville, for research into the bacteriological aspects of diagnosis or control of animal disease—The High Commissioner for New Zealand, 415 Strand, London, W.C.2, quoting Ref No A.3/4/37 (August 19).

LECTURER IN GEOLOGY, with special reference to petrology—Head of the Department of Geology, Imperial College of Science and Technology, Prince Consort Road, London, S.W.7 (August 19).

LECTURER (with a recognized qualification in mining, mine surveying or mechanical engineering) IN THE DEPARTMENT OF MINING AND GEOLOGY—The Principal, Wigan and District Mining and Technical College, Wigan (August 19).

CHAIR OF HYDRAULIC ENGINEERING at the University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, August 20).

CHEMIST (Research Officer) (with a university honours or high degree in science, with chemistry as a major subject or equivalent qualifications) in the Plant Fibre Section of the Commonwealth Scientific and Industrial Research Organization, Highett, Victoria, Australia, to undertake research on the chemistry of fodder conservation with special reference to the protein content—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting 400/61 (August 20).

LECTURER (with special qualifications in physical chemistry) IN CHEMISTRY—The Secretary, The University, Aberdeen (August 20).

RESEARCH CHEMIST (with a university honours degree in chemistry and research experience in the field of surface chemistry or coal chemistry) in the Coal Research Section of the Commonwealth Scientific and Industrial Research Organization, North Ryde, Sydney, N.S.W., Australia, for investigations of the surface and electrical properties of Australian coals and cokes made therefrom, as part of a general programme of research into coal carbonization—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting 480/170 (August 20).

DEMONSTRATOR IN THE DEPARTMENT OF INORGANIC CHEMISTRY—The Registrar, King's College, Newcastle upon Tyne (August 31).

LECTURER IN THE DEPARTMENT OF CIVIL AND MECHANICAL ENGINEERING—Joint Clerk to the University Court, Queen's College Dundee (September 15).

CHAIR OF ANATOMY at the University of Cape Town, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Cape Town, September 17).

ASSISTANT, Grade A (with a good honours degree) FOR MATHEMATICS—The Clerk to the Governors, South-East Essex Technical College and School of Art, Longbridge Road, Dagenham.

ASSISTANT LECTURER (with a degree or equivalent qualification) teach Chemistry to the level of B.Sc. general degree and high national certificate—The Registrar, Medway College of Technolog Maidstone Road, Chatham.

ENGINEERS and PHYSICISTS, Experimental Officer and Assista Experimental Officer grades, in Royal Naval Scientific Service Expe mental Establishments in the London, Portsmouth and Weymou areas, Gloucestershire and Scotland—The Ministry of Labour a National Service, Technical and Scientific Register (K), 26 Ki Street, London, S.W.1, quoting A214/5A.

MASTER TO TEACH PHYSICS and some CHEMISTRY—The Director Studies, The Nautical College, Pangbourne.

PHYSICAL CHEMISTS (graduates, with research experience a preferably of Ph.D. standing) for research on (a) thermodynamics absorption (Ref. P.C.1); and (b) the mechanism of precipitation high polymers from solution (Ref. P.C.2)—The Appointments Offic British Rayon Research Association, Heald Green Laboratori Wythenshawe, Manchester 22, quoting appropriate Ref. No.

RESEARCH ASSISTANTS (2) IN PHYSICAL CHEMISTRY, to work problems connected with the combination of amino-acids with sug —The Clerk to the Governors, South-West Essex Technical Colle and School of Art, Forest Road, Walthamstow, London, E.17.

SCIENTIFIC OFFICERS (with a first- or second-class honours degr in physics or mechanical engineering, and preferably with resear experience in the field of mechanics) to assist in a group studying t effect of vibration and impulse stresses on weapon assemblies—Seni Recruitment Officer, Atomic Weapons Research Establishme Aldermaston, Berks, quoting 703/WGH/34.

SENIOR SCIENTIFIC OFFICER (with a first- or second-class honou degree in physics and some experience in the theory, design a application of electric measurement or gauging instruments), develop instruments for measuring thermal and mechanical distorti in weapon assemblies—Senior Recruitment Officer, Atomic Weapo Research Establishment, Aldermaston, Berks, quoting 702/WGH/

# TRANSPORT POLICY IN GREAT BRITAIN

T is now more than two years since the Minister of Transport, then Mr. A. Lennox-Boyd, stated in e House of Commons that to delay an extended ogramme of major road improvements in Great itain would cause serious damage to the economy the country. At that time the total Exchequer penditure on the schemes to be authorized in the xt three financial years was not to exceed £50 illion, and no major reconstruction schemes to restall serious damage to our economy were conmplated. Within two years, however, the Governent was forced, almost simultaneously with its ans for reconstructing railways, to formulate plans r expending £147 million, spread over four years, a roads, together with an average of about £117 illion per annum.

The plans announced by Mr. J. A. Boyd-Carpenter a February 2 provided for new motor-ways from ondon to Yorkshire and from Preston to Birmingam, but at a date still unspecified. A start was to e made with a crossing of the Firth of Forth, though e decision between a concrete tube moored to its ed, estimated to cost £5·5 million, and a bridge sting £15 million had still to be made. A new high-vel bridge over the Manchester Ship Canal was to e built as part of the Manchester outer ring road, nd there were a number of subsidiary and very seful improvements to be made to existing roads; ut there were some notable omissions, such as the evern scheme and the Tamar bridge. It was also nnounced that the Government was prepared to onsider charging tolls where appropriate.

There was no indication in Mr. Lennox-Boyd's atement that the Government is ready to tackle ad reconstruction with the urgency that, on its own howing, is required, and the merits of the individual hemes *do not suggest that reconstruction* is being lanned as a whole; rather it seems to be a series f piecemeal improvements. The plans made on aper give no sign of comprehensive policy, or that he old tradition that roads are a local responsibility being combated. The Minister of Transport is till directly responsible for little more than eight housand miles of road out of more than 180,000 on hich public money is spent, and to more than half he total mileage of roads in Britain the central overnment contributes nothing. Road construction nd efficiency thus depend largely on the enterprise nd vision or indifference—and on the reluctance or illingness to spend local rates primarily to benefit hrough traffic—of nearly 1,300 local authorities.

Schemes for 340 miles of new motor roads which Ir. Lennox-Boyd's successor as Minister of Transport, Ir. Boyd-Carpenter, announced on July 5 as a rst instalment of the Government's plans the day fter the Road Traffic Bill had received its second eading in the House of Commons show, therefore, a elcome advance. Nevertheless, they scarcely easure up to the urgent need during the next wo decades to spend more of the national income pon roads and such facilities as bridges, fly-overs, etc., designed to increase the efficiency of roads and their adequacy to the traffic they carry. Although it is expected that all the new motor roads will be completed within ten years, and that a start will be made on all within four, it will still be nearly ten before the major projects are complete. Inclusive of land purchase, they are expected to cost on average about £250,000 a mile. Including seven by-passes totalling 84 miles and costing some £20 million, the total cost is estimated at £85 million, and by 1959 annual expenditure on roads will run at about £50 million a year.

The two motor-ways specifically described by Mr. Boyd-Carpenter are a first section of fifty-three miles of the London–Yorkshire motor way between St. Albans and Dunchurch, near Birmingham, and one of 94 miles between a point north of Birmingham and the Preston by-pass. The by-pass roads will be built to motor-way specifications, and the Ministry has endeavoured to incorporate the lessons of Continental and American experience. The London–Yorkshire motor-way will have six fly-over junctions, at four of which it will be joined by slip-roads to a roundabout built above or under the motor-way on the level of the existing road, and there will be no access to the motor-way except at these points. Parking will be prohibited except in lay-bys, and although it is expected that the acquisition of land and other preparatory work may take up to two years, thereafter the work should go ahead quickly. It is anticipated that the lines of the new roadways will be indicated precisely in September.

Mr. Boyd-Carpenter's statement indicates that the Government is drawing on the full range of technical experience of other countries as well as on the knowledge placed at its disposal by the work of the Building Research Station (Department of Scientific and Industrial Research). The timing of the programme, however, scarcely suggests that the Government is alive to the urgency of the task of matching what is largely an eighteenth-century road system to the needs of mid-twentieth century traffic, or to the speed of construction made possible by the recent great advances in the mechanization of road construction. The civil engineering industry has stated categorically that materials and skilled man-power for doubling the size of the present programme are available. Admittedly these resources cannot be deployed until the surveys involved and acquisition of the land required have been completed; but that is a further reason for planning on a larger scale, so that the full technical resources available can be put into operation immediately the more time-consuming operations of survey have been completed and legal problems settled.

That makes it the more imperative that the Government should now detail its plans for road construction and improvement as part of a national policy for roads, which itself forms part of an even larger policy for transport, taking full account not only of rail transport but also of the contribution which other forms of transport such as canals and aviation, including helicopter services, could bring to the alleviation of congestion and use of the roads. The recent railway strike showed that there is still a good deal of traffic that could go by road rather than by rail, and that the fullest use was not yet being made of available road services, disregarding the congestion which retards their efficiency. It is no less true, however, that much heavy traffic goes by road which does not contribute in proportion to the damage it does to road surfaces, or the congestion it causes, and which from the national point of view should go by rail. Further, as was remarked in the House of Commons, the high cost of transport is already encouraging private transport instead of the use of public transport to an extent that increases congestion and makes the public service vehicles still less remunerative.

It is for such reasons that the plans announced by Mr. Boyd-Carpenter are disappointing, though they might have been more acceptable had they been presented as part of a comprehensive plan and accompanied by unmistakable evidence of a sense of urgency and of determination to grapple with the issues with imagination and energy. Much of the criticism of the Road Traffic Bill arises from a similar cause. As Mr. Boyd-Carpenter quite rightly said in concluding the debate on the second reading of the Bill on July 4, it is only intended to embody that part of a policy which requires a change of the law; but he gave little indication that the Government has thought out the comprehensive policy implied by his remarks.

The Road Traffic Bill embodies some good features which did not receive due recognition in the debate, notably in giving the Government power to start experiments in traffic control and in dealing with congestion. Essentially it is a measure designed to increase road safety and to reduce congestion, and in introducing the Bill, the Joint Parliamentary Secretary to the Ministry of Transport and Civil Aviation, Mr. Hugh Molson, claimed that it rested on the three determinants of road safety stressed by the Departmental Committee—the application of technical or engineering skill, education and enforcement. It embodies indeed, as the Minister himself claimed, the major part of the Government's policy in respect of congestion and of road safety, and he made the important admission that the major road programme assumed that there would continue to be a very great expansion in the number of vehicles on the roads of Britain. By 1980 there will probably be four times the number of private motor-cars on the road than there were in 1939, and twice the present number.

Accordingly, it is the more important that bad, dangerous and incompetent driving should be penalized severely, because in the future dangerous driving will become an even grosser social evil than at present; it is from this point of view that the penal provisions of the Bill are a subsidiary part of a major road programme. As such, however, they appear to be open to two criticisms. The root difficulty with driving offences is the present uneven administration of the law. To remedy this may well be essentially a matter of public education; but t debate on July 4 indicated that the Governme would receive plenty of support if withdrawal of driving licence were made an automatic consequen in any conviction for dangerous driving. The seco criticism relates to the renewal of provisional drivi licences. Apart from the question of the number competent examiners, some attempt should be ma to check the repeated issue of provisional licences holders who have not attempted to take the te The sensible suggestion has been made that a seco or third provisional licence should be made incre ingly expensive for those who have not attempted take the test when opportunity has been offered.

There are two other main points of criticism the Road Traffic Bill which were freely expressed the debate and to which no adequate answer w given by the Government. The first of these is relation to parking. The use of parking meters m well be worth trying; but provision of adequa parking space off the streets is a matter of urgen which cannot be shelved, even if it involves a co comitant problem of bringing more traffic into th large towns. Mr. Ernest Davies commented in th connexion on the freer flow of traffic throug London during the railway strike, which he attribute to three factors: the increased restriction on parki in Central London; manual direction of traffic b the police; and the acceptance by drivers of t necessity for these further regulations and the consequent co-operation with the police.

These matters obviously involve problems public education and understanding, both of whic are important factors in the second and more seriou criticism made of the Bill. The Government h decided for the time being not to make the testin of vehicles compulsory in Great Britain. The pr posals to that end embodied in the Bill introduced i the previous session admittedly had serious practic difficulties; but in a matter involving public safet to this extent, Mr. Molson's reason for dropping th proposal was inept. After establishing a convincin argument for compulsory tests he added tha although the Government believed inspection vehicles would reduce the number of road accident if public opinion was not prepared to put up wit the additional interference and inconvenience, it wa unwise to try to legislate ahead of public opinion.

That is an abdication of public responsibility whic ought not to be tolerated, and apart from the risk to life and limb involved, it deprives the public the benefit which expert knowledge could contribut to road safety. It may well be that a system inspection of all vehicles is at present impracticable but a start could be made with the inspection of a vehicles of more than a specified age. In addition the Government, on the evidence before it, should b undertaking a campaign of public education designe to secure full support for a more drastic policy at a early date, and it should also be seeking the mean by which to implement that policy through th provision of appropriate inspectors.

Road policy has two main aspects, and these ar not opposed as is sometimes implied. There is th

ect of road safety, and there is the economic or
ductive aspect. Both are social, and neglect of
her has anti-social as well as economic consequences.
e country can ill afford the continued toll of life
ich defective vehicles and dangerous driving take
ek by week, and the Federation of British Indus-
es and the Trades Union Congress agree that
proved roads would be the biggest single contri-
tion to higher productivity.

Road policy is, however, interlocked with transport
licy generally, and with the larger question of the
of land and of urban as well as rural development,
d there are implications for local government.
at is why a series of piecemeal improvements or
ojects is regarded with distrust unless it is
esented with clear evidence that the wider im-
cations have been considered. As Mr. Strauss
narked, much traffic at present on the roads could
, and in the national interest should go, on the
lways, and he also suggested that expenditure of
million upon canals might be more advantageous
an a like or greater expenditure upon new roads.
Mr. Strauss was undoubtedly right in urging that
possibility of making greater use of canals in
ure should be an essential part of any study for a
mprehensive traffic policy, and the Government
arly must make up its mind what action to
ke on the report of Lord Rusholme's Board of
rvey of Canals and Inland Waterways. Some
licy for canals is essential and any such policy will
volve expenditure; to neglect this on the excuse
at we have already to face a plan for modernization
the railways will involve waste rather than saving
our resources.

Inland transport in Britain, it cannot be too
ongly emphasized, must be considered as a whole
d in relation to the implications not only of
entific advances in road construction, in electric
nsport, the diesel engine and the utilization of
l, but also in relation to the rising costs of solid
l, labour and the potentialities of nuclear energy.
is a problem to which the contribution of the
entist and technologist is indispensable; but it is
o a problem with which the scientist and tech-
logist are concerned as citizens as well as pro-
sionally. For that very reason they are the better
uipped to participate in the task of public education
ich will be required as part of any comprehensive
licy if success is to be achieved; and they should
o be qualified to help to keep the discussion of the
ge issues involved objective and free from political
ejudice. The Government's plans for road con-
uction and for the modernization of railways
d the Road Traffic Bill raise issues which concern
ny scientists professionally. But they also chal-
ge all scientists to take part in the task of public
ucation which the framing and execution of a
nsport policy embodying the full advantages of
ientific advance demand; the administrative
anges alone required for any adequate and effective
stem of supervision as well as planning of the road
stem of Britain as a whole are immense, and will
t be acceptable unless they are understood and
eive full support.

# THE PROTEINS ENCOMPASSED

**The Proteins**

Chemistry, Biological Activity, and Methods. Edited by Hans Neurath and Kenneth Bailey. Vol. 2, Part B. Pp. ix+663–1418. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1954.) 16.50 dollars.

THE final volume of this four-volume work has now appeared, so that it is possible to consider balance and completeness of the whole. Different editors would probably have divided up the subject somewhat differently, and different types of protein might sometimes have been used as examples. But there are no glaring omissions. There may, however, be some inconsistencies; thus, nucleoproteins have a chapter to themselves, while mucoproteins and lipoproteins are dealt with incidentally and so have to be searched for in the index. A general survey of those proteins which are firmly attached to 5 per cent or more of material other than amino-acids would have been valuable, particularly if it had discussed the nature of the links between the peptide moiety and the prosthetic group.

There are six articles in the volume, each ninety or more pages long, and some of them would have made excellent monographs. The doubts about the usefulness of binding monographs together, already raised when reviewing the third volume (*Nature*, 174, 762; 1954), may be repeated. Some articles will get out of date much sooner than others, and separate publication of sections would make revision easy.

W. L. Hughes discusses the various functions that a circulating plasma might be expected to play and then considers, for each plasma fraction in turn, the evidence that it fills a specific role—for example, that it is a hormone or protection against an infective agent, or that it has a general nutritive or solvent function. Protection is considered in more detail in the chapter by W. C. Boyd on immune reactions. He gives a clear account of the diffuse fields of antigenic specificity and of the nature of the union between antigen and antibody. The final picture is as valid and comprehensive as could have been drawn in the space, though it contains a few irrelevant surprises: What, for example, is the evidence that "most plant proteins seem to be good antigens" or that protein synthesis goes on in viruses? Many would argue the contrary.

There are two articles on structure proteins: J. C. Kendrew on silk, keratin and collagen, and K. Bailey on muscle. In many other articles in these volumes the assumption is made, sometimes explicitly, that proteins with defined functions have unique structures and that heterogeneity in the preparations is a consequence of damage to the protein or of admixture with other proteins. It is pleasant, therefore, to find Kendrew emphasizing that homogeneity is a term with no relevance to insoluble proteins. Bailey starts his survey with Moses and Aristotle. The conclusions of more recent authorities on the interrelation of the actions of the various muscle enzymes are described lucidly, and stress is laid on the difficulties introduced into attempts at muscular micro-anatomy by the tendency myosin has to adsorb enzymes with which it may not have been associated *in vivo*. Both chapters make good use of the X-ray and electron microscope evidence that has been brought to bear recently on the problem.

N. M. Green and H. Neurath discuss proteolytic enzymes. They assemble a vast amount of evidence about the kinetics of action of different enzymes on substrates of known structure. It is puzzling that out of this no positive suggestion has yet come about the nature of the active spot on a protease. There may already be abundant hieroglyphs on this Rosetta Stone but neither a Young nor a Champollion to read them! Two points now seem to be clear: there is only one active site on some enzymes, and the proteolytic site is also used when the enzyme catalyses transpeptidization.

The final article is the most ambitious. H. Tarver, discussing peptide and protein synthesis and protein turnover, arouses the reader's suspicions at the start by claiming objectivity. This presumably is what the other contributors to these volumes were aiming at, and they seem to have been no less successful in achieving it. However, the article gives a useful survey of a difficult field and comments shrewdly on the gap there often is between the interpretations that follow of necessity from a set of observations and the interpretations that are published. Tarver discusses the alternative possibilities—that proteins are in a state of flux with a regular 'turnover' or that they are stable in the environment in which they were synthesized. No positive conclusion can yet be reached; perhaps because in this respect, as in others, proteins are protean.

N. W. Pirie

---

# HISTORY OF TECHNOLOGY

## A History of Technology

Edited by Charles Singer, E. J. Holmyard and A. R. Hall; assisted by E. Jaffe, R. H. G. Thomson and J. M. Donaldson. Vol. 1: From Early Times to Fall of Ancient Empires. Pp. lv+8 maps+828+36 plates. (Oxford: Clarendon Press; London: Oxford University Press, 1954.) £7 7s. net.

This book presents the first of five volumes of a wide-ranging history of technology for which the English-speaking nations will be envied by others. The whole work will deal with the development of technology from the Stone Age down to the end of the nineteenth century. Its publication has been made possible by the help of Imperial Chemical Industries, Ltd., an organization which has shown its interest in the history of science and technology by publishing the very attractive and useful periodical *Endeavour*.

The very great amount of material for the present work has been divided up between a large number of well-known men of science, working under a triumvirate of editors, headed by that distinguished historian of science and medicine, Dr. Charles Singer, in whose honour his colleagues published two years ago a *Festschrift*, "Science, Medicine and History" (London, 1953), in two volumes. The second and third editors are E. J. Holmyard, the historian of chemistry, who was also the editor of *Endeavour*, and A. R. Hall, the historian of the natural sciences, well known also as the author of an excellent history of ballistics in the seventeenth century (Cambridge, 1952) and of a history of the scientific revolution, 1500–1800 (London, 1954). What is perhaps missing is the name of a historian of technology among the editors, but Dr. Singer's field of research is so wide that one can also reckon him in this category; one need only think of his masterly treatise on the history of the alum industry ("The Earliest Chemical Industry", London, 1948). Apart from this, the advice a prominent British historian of technology, H. Dickinson, was sought during the planning of t five volumes, but unfortunately he died in 1952.

The work is not meant for historians of technolo only, but rather as a contribution to a reade general technical education. Its intention is to gi to students and research workers in the field technology and applied sciences the humanistic a historical background of their studies. It is design to show them that the problems of their specialis studies have had a long history and have originat in different civilizations. The work will also be use to history students in general by showing them t development of material culture.

The first volume covers the period from t palæolithic age to the downfall of the empires of t ancient East. Part 1 starts with a history of t fundamental social conditions of early humani K. P. Oakley deals with man as tool-maker, a V. Gordon Childe then discusses the early forms society, in which he gives a good definition of t term 'technology'. H. S. Harrison describes how t early inventions were made, developed and sprea A. Sommerfelt deals with the problem of languag and R. E. Leach concludes Part 1 with an artic about the primitive calendar.

Part 2 is devoted to the age of the hunter a hoarder. L. S. B. Leakey writes on the technolo of stones, bones and wood, and, in another co tribution, with palæolithic art. Daryll Forde describ the early ways of hunting and fishing. As to tra for animals (p. 177), mention might have been ma to J. E. Lips's "The Origin of Things" (New Yor 1946), in which book a very vivid description those first machines of mankind is to be found.

Part 3 is devoted to domestic activities. Gord Childe writes very instructively about rotary mov ment and the early history of the drill, the potte wheel and the carriage wheel. In his bibliograph (p. 214) he might have mentioned the instructi papers of H. T. Horwitz ("Die Entwicklung d Drehbewegung" in *Beiträge zur Geschichte der Techni* 10, 179; 1920) and of O. Mahr ("Zur Geschichte d Wagenrads" in *Technikgeschichte*, 23, 51; 193 H. S. Harrison introduces his readers to the ear ways of firemaking and of using materials for heati and lighting. The picture (p. 217) on "The Dome tication of Fire" from the Parisian edition Vitruvius (1547) is only a free reproduction of t woodcut in the famous Vitruvius edition of 152 published at Como. The pneumatic firelighter ( 227) was no doubt only introduced to Borneo b the Portuguese in the nineteenth century, and ca therefore not be said to be autochthonous. R. Forbes, who is well known through many of h papers as a historian of technology, writes about t technology of chemistry, cookery and cosmetic The last article of Part 3, by J. Bradford, describ very vividly the different forms of structures whi were made by using wood, woven reeds or turf.

Various technical activities are considered i Part 4. F. E. Zeuner deals with the domesticatio of animals and the cultivation of plants; to th bibliography, H. Nachtsheim's book, "Vom Wildti zum Haustier" (second edition, Hamburg, 1949 might usefully be added. Sir Lindsay Scott tells th early history of pottery. In an excellent pape G. M. Crowfoot deals with textiles, straw plaitin and mat-making. Two appendixes by J. Grant an K. R. Gilbert deal with the materials of ancie tiles, basketry and rope-making. Then follow pers about bricks and stone structures (S. Lloyd), e Stonehenge monument (R. H. G. Thomson), the ferentiation of non-metallic utensils (S. M. Cole) d the use of irrigation and agriculture (M. S. ower).

Part 5 deals with the use of metals. Mines and arries are dealt with by C. N. Bromhead. R. J. rbes describes how metals were won from ores, d how they were melted and alloyed. H. H. gblan deals with utensils and metal weapons, H. aryon and H. F. Plenderleith with fine metal-crafts, . D. Barnett with objects made of ebony, and C. dred with artistic woodwork.

The subject of transport is the theme of Part 6. M. Cole describes wheeled vehicles and deals with ads and bridges. Wheeled vehicles are also scribed by Gordon Childe. The part is concluded A. Digby's paper on boats and ships down to the pe of the Ægean galley.

Part 7, the last one in the volume, considers ings essential for the development of natural iences: S. H. Hooke tells the history of writing, . G. Skinner that of weights and measures, and O. eugebauer that of mathematics and astronomy in e Ancient Orient.

The book is splendidly illustrated, most impressive ing the thirty-six photographic plates. Some of e contributions have excellent bibliographies; but hers have none at all—which is a pity. Each article ould have its own bibliography; it is not enough direct the reader's attention to R. J. Forbes's Bibliographia Antiqua" (Leyden, 1940–50). It need arcely be said that a standard work like this s a detailed index. Special features are the ronological tables by F. E. Zeuner covering the eriod from the geological ages down to the birth of hrist, and the chronological tables of prehistoric d historical civilizations of the Near East. In nclusion, I should like to say that the work succeeds achieving its objects, as might be expected from e profound knowledge and truly humanistic outok of its editors and contributors. We are waiting ith impatience for the other volumes.

# A POLICY FOR WAGES

## he Social Foundations of Wage Policy

Study of Contemporary British Wage and Salary ructure. By Barbara Wootton. Pp. 200. (London: eorge Allen and Unwin, Ltd., 1955.) 15s. net.

THERE is much in this book by Mrs. Barbara Wootton that is familiar to students of economics d industrial relations. The limitations of economic eory which seeks to explain the process of wage etermination on the basis of a set of highly unalistic assumptions have long been the cause of issatisfaction both to economists and to those who ok to theory as a possible source of guidance in ractical affairs. Equally, the failure of theoretical nalysis to account satisfactorily for what the author escribes as curiosities of British wage structure—xtreme inequality of rewards far beyond the range f individual differences in inborn aptitudes or in sts of training; the lack of an inverse relationship etween the monetary and non-monetary attractions different jobs, or of a positive relationship between e length of the normal working week and the standard time-rate of wages; variations in the practice of differentiating wage-rates according to sex—is a not unfamiliar theme, and much of the description and comment on methods of wage determination, on the attitudes and policies of trade unions, employers and arbitrators are inevitably part of the common stock-in-trade of all those whose professional or academic interests lie in the field of industrial relations.

Nevertheless, one of the great merits of Mrs. Wootton's work is her vivid and spirited presentation of familiar arguments, accompanied by penetrating observations based on a long academic and practical experience, to demonstrate once more that the economist's highly simplified account of the process of wage determination must be supplemented and modified by analysis of the institutional, social and ethical considerations surrounding the wage bargain. With this book, Mrs. Wootton joins the growing company of challengers, from Mr. J. W. F. Rowe in Britain to Mr. A. M. Ross in the United States, whose work may stimulate attempts to reformulate economic theory in this very significant area.

Analysis of these non-economic considerations is held to show the existence of two distinct and opposing sets of forces: ethical considerations—justice and fairness—are said to pull in the direction of equality; social considerations—status and prestige—make for conservatism and the maintenance of traditionally established differentials. In a wide survey of wage negotiation and arbitration in recent years, Mrs. Wootton concludes that, notwithstanding the tendency to phrase the arguments in ethical terms, the emphasis on the social factors of status and prestige has tended to produce an increasing degree of rigidity in the wages structure. Moreover, since conservatism justifies itself, no principles need be sought, and thus expediency or reference to custom becomes the rule.

This absence of principles of decision prevents the development of a coherent wage policy and stultifies the work of negotiators and arbitrators. So far as arbitration is concerned, the lack of principles has, of course, long been recognized as a major difficulty. Contrary to Mrs. Wootton's statement that, in the report of the 1954 court of inquiry in engineering, "the true nature of the problem here was explicitly stated at last", the difficulty was in fact recognized in the Report of the Royal Commission on Trade Unions of 1867–69, which rejected compulsory arbitration on the grounds that "there are no admitted principles of decision on which an arbitrator may proceed". For Mrs. Wootton, arbitration is a judicial process in spite of the absence of principles or of governmental statements of policy. In fact, however, it may be regarded as a legislative process, since the arbitrator is not being asked to interpret existing laws but to make a new law—a situation which led Parliament throughout the nineteenth century consistently to refuse to grant compulsory powers to arbitrators despite the widespread desire to strengthen the system of arbitration. Mrs. Wootton would not only require Parliament to legislate, in very broad terms, on wages policy, but also would expect negotiators and arbitrators to act as interpreters of this legislation. This proposal, quite apart from its merits, ignores the practical difficulties, which also beset the idea of compulsory arbitration, of enforcing the law against the very large groups of aggrieved workers which may emerge under certain conditions.

Finally, in addition to advocacy of guidance in wage policy by pronouncements of economic planning, the one principle suggested by Mrs. Wootton, that of equality, appears to spring from a particular set of social and political beliefs rather than from any practical consideration of the unquestionably urgent problems involved in the present wages situation in Great Britain.

## PHYSICS IN ONE VOLUME

### Textbook of Physics

Edited by R. Kronig, in collaboration with J. De Boer, H. C. Burger, P. H. Van Cittert, C. J. Gorter, A. C. S. Van Heel, P. Van Der Leeden and G. J. Sizoo, with biographical notes and tables by J. Korringa. (Translated from the Third Dutch Edition published in 1951.) Pp. xv+856. (London: Pergamon Press, Ltd.; New York: Interscience Publishers, Inc., 1954.) 70*s*. net.

A DISINCLINATION to believe that he has ever known more than could be put into one book has often persuaded the reviewer to hope for a single comprehensive text-book of physics which could be safely recommended to students and which could be used as an occasional refresher for himself—now happily beyond active service in examinations.

This English translation of a very successful text-book written by a group of Dutch physicists during the Second World War is probably the most ambitious attempt yet made at providing in one volume an account of physics as a whole at a reasonably advanced level. It would be easy to make criticisms of detail or complaints about particular omissions; but a more appropriate treatment—which this book deserves—would be to attempt to explain what it does and does not succeed in doing.

First, as would be guessed from the names of the contributors, the treatment is of high quality. Its level is roughly that which an honours student might aim to reach at the end of his second year; it would not be adequate for a third year in which any specialization was permitted. It is modern in outlook on the whole; for example, in discussing elasticity it mentions interatomic forces, but does not describe all the variations possible in the measurement of surface tension. It does not deal only with theoretical principles, but gets down to such practical details as the design of optical instruments. In general—though not everywhere—the phenomenological description is placed first; there are, for example, fifty pages on vibrations and waves early in the book. Unusual features include a section on medical physics and a collection of biographies of famous physicists.

However, the final and perhaps inevitable verdict must be that too much of the matter has been over-condensed. Perhaps two volumes really are necessary. To take a few examples at random: the cyclotron is dismissed in half a page, the Linde method of liquefying gases in two lines, infra-red spectroscopy in two separated paragraphs, piezo-electricity and ultrasonics in half a page. In the first chapter, in which an account is given of the objects and methods of physics, a discussion of errors is given which occupies only half a page, and an even shorter discussion of graphical methods. To be frank, one cannot imagine a student deriving much from su abbreviated accounts unless he is also pursuing normal course of physics and has access to oth books. In other words, this book must be regard as additional reading. In this capacity it would greatly stimulating to a serious student of phys Within these limits, the book is about as good as o written by a group of authors could be, and probat better than one author could hope to write.

The diagrams are excellent, and the writing is fr from eccentricities often found in translated wo The price, though high, is probably—in terms pence per word—a good deal lower than the prese day average.

## GLOSSARY OF COALS

### Coals and Bitumens and Related Fossil Carbo aceous Substances

Nomenclature and Classification. By Dr. S. Tomkeieff. Pp. v+122. (London: Pergamon Pre Ltd., 1954.) 17*s*. 6*d*. net.

A GLOSSARY of this wide and unsystemat subject has long been needed, and yet ha never been made; it is admirable to have it nov Dr. S. I. Tomkeieff's book contains some thirtee hundred terms, of which all but about two hundre relate to coal. The body of the book lists the alphabetically, with short definitions and reference This is followed by a series of synoptic tables an some diagrams, which give schematic order to th bewildering variety of names and substances. Th methods of these classifications are explained in short introduction.

Dr. Tomkeieff has done his work well. Where s much of the matter is traditional and local, gaps ca of course be found, and there are some oddities c usage. But the book is a remarkable collectio across a multitude of dialects and even languages— there are nearly two hundred terms in some twent foreign languages.

The interests of the author are those of the geo logist rather than, say, the coal chemist, and in thi respect the book falls short of the needs of the latte For example, such important technical terms a 'volatile content' and 'carbon ratio' are defined i ways which are no longer the best standard practice There is no classification of coals by the paramete of their ranks; and, most serious, the importan modern work on the physical and chemical structur of coals is not mentioned. Outstanding progress ha been made during the past few years in understandin the properties of different coals, by deductions mad from their examination by X-ray, infra-red, an other physical methods. These researches offer th best promise for bringing order of a fundament kind into the present empirical classifications; an the neglect of such ideas in this book is therefor regrettable.

The next edition would be greatly strengthened b including in the introduction a systematic accoun of modern physical and chemical theories of coa structure, and by adding to the synoptic tables an diagrams a classification based on them. In it present form, Dr. Tomkeieff's book is thoroughl useful; with these additions, it would become indis pensable to all students of coal and allied substance

J. Bronowski

## nalyse Spectrale Quantitative par la Flamme

-Propriétés de la Flamme : Réalisation et Util-
tion. 2—Analyse des Émissions dans la Flamme.
r Dr. R. Mavrodineanu et H. Boiteux. (Pub-
ation de l'Office de la Recherche Scientifique Outre-
r.) Pp. vi+248+11 plates. (Paris : Masson et Cie.,
54.) Broché 3,800 francs ; Cartonné 4,800 francs.

N this volume, an excellent account is given of the
theoretical and practical aspects of flame photo-
try. The book is divided into two parts, the first
aling with the general properties of flame sources
d a very comprehensive consideration of the factors
ecting the design of burners, atomizers and other
mponents in a complete flame photometer. There
chapters on photoelectric and photographic
thods, and also on instruments with dispersing
stems and with filters. A short account is given of
e interferences between different elements.

It is easy to suggest additional material which
ght have been included in any book, but perhaps
fuller account could have been given of the large
ount of work done in recent years on photoelectric
struments, and reference made to the value of
terference filters. The effect on flame temperature
the introduction of different salts also deserves
tention, as one cause of interference between one
ment and another.

The second part of the book is concerned with the
eory of the emission spectra of the flame itself and
the elements and compounds giving lines used for
alysis. Its value lies in the inclusion within a
gle volume, not only of the spectral terms and
ergy-levels of a great many elements, but also of
full account of the molecular spectra of interest
d the chemical reactions and equilibria within the
me. A list of useful spectral lines, and photographs
a number of flame spectra are included. There is
extensive bibliography of more than five hundred
ferences, and a good index. The book makes a
stinct contribution to a subject which has not
cently been presented in a form primarily intended
r the analyst.

J. R. Stansfield

## eology of Petroleum

y A. I. Levorsen. (A Series of Geology Texts.) Pp.
+703. (San Francisco : W. H. Freeman and
mpany ; London : Bailey Bros. and Swinfen,
d., 1954.) 8 dollars ; 68s.

EOLOGIES of petroleum have in the past tended
to a pattern of theory first, and practice second.
such works the principles are enunciated, explained,
agrammatically presented, and thereafter followed
ually with geographically arranged oilfield strati-
aphies and structures. Sometimes descriptive
atter is too detailed, and a monotonous record of
st developments is given ; these date quickly
less particularly exemplary. However, the author
this present book is fully aware that there is no
int in cataloguing producing pools except as they
ustrate specific principles that apply to exploration,
r our first interest is in finding new producing areas,
d this point of view is much to be commended.

Unrelieved oil geology, without full leavening of
ntacts with closely allied sister sciences, lacks
spiration and reality. Recognizing this, the author
eats his material objectively : first the reservoir
mphasis on trap rock) ; then reservoir conditions
mperature, pressure, differential fluids) ; next
peculative ideas on origin, migration and accumu-
tion" (the operative word here is 'speculative') ;
d finally, "ways of applying what has been considered in the search for new pools and provinces". There is logic in this sequence. Geological manuscripts are inevitably read in terms of economic values, and theories put to practical trial by drilling. The experienced oil geologist can interpret his findings understandably to geophysicists, reservoir and production engineers and the like ; and this applies to administrative 'laymen' as well. Reciprocally, many of these other people desire to learn from a not too technical, modern text something of the geologist's technique. This is the book for them ; its appeal should be deservedly wide.

H. B. Milner

## Entire Functions

By Ralph Philip Boas, Jr. (Pure and Applied Mathematics : a Series of Monographs and Textbooks.) Pp. xi+276. (New York : Academic Press, Inc. ; London : Academic Books, Ltd., 1954.) 6 dollars.

THIS book presents in orderly fashion a wealth of material not previously brought under one cover. It is about functions of exponential type, with emphasis on entire (integral) functions. There are chapters on entire functions of finite order, the minimum modulus and functions with real negative zeros. Then follows a chapter on general properties of functions of exponential type, and then three chapters on special properties, such as the connexion between growth and the distribution of zeros. There is a chapter on uniqueness theorems, and this is followed by a chapter on growth theorems and one on operators and their extremal properties. The last chapter, on applications, is exciting because it demonstrates the wide field within which entire functions find a place. Illustrations are given of applications to Fourier series, power series on the circle of convergence, Dirichlet series and gap theorems. There are brief sections on differential equations of infinite order and approximation. It is a pity that these are so short ; but there is an extensive bibliography for those requiring more detail.

A survey of the present book shows that the subject-matter of the theory of entire functions consists of a great number of more-or-less special results. The indications are that these are becoming overwhelming in their numbers and ramifications. One is led to ask the question whether some general theory might be developed which will compress a lot of the known results into several strong channels. It certainly looks as if some new method of classification is needed. It may be that modern algebra and topology can help here, via such tools as ultrafilters and the structure theory of complete local rings, as used recently by Henriksen and others.

L. S. Goddard

## Physics for Medical Students

By Dr. J. S. Rogers. Third edition, revised and enlarged. Pp. xiii+405. (Melbourne : Melbourne University Press ; London : Cambridge University Press, 1953.) 35s. net.

FOR some twenty years Dr. J. S. Rogers's book has done admirable service in providing a course which supplements the ordinary university physics text, with applications of special interest to medical students. In this, the third edition, developments of nuclear physics and electronics are included, together with topics such as reflecting objectives and phase-contrast microscopy. Outstanding in its own field, the book will be gladly welcomed in this new edition.

G. R. Noakes

# THE AGES AND ORIGIN OF METEORITES

By Dr. P. REASBECK*

Londonderry Laboratory for Radiochemistry, University of Durham

AND

Dr. K. I. MAYNE

Clarendon Laboratory, University of Oxford

THE geological ages of meteorites have been discussed recently by several authors[1-8]. Paneth's classical helium method based on analyses for helium, uranium and thorium, now taking into account the helium generated also by cosmic rays[4,5], is being supplemented by the argon–potassium method[6-8]. The latter is, of course, only applicable to the stony phase of meteorites, since the iron phase contains too little potassium. It is clearly of interest to compare the apparent ages derived from both experimental methods. Two questions may now be posed: First, is there agreement in the ages found by both methods applied to identical samples of meteoric stone? Secondly, do either of these ages agree with that found by the helium method applied to meteoric iron? If the answer to the first question is in the affirmative, one can have much more confidence in the derived ages than one would have by either method alone. Granted this agreement, the answer to the second question cannot then fail to be significant in a discussion of the life-history of these bodies.

Table 1

| Meteorite | Helium content (in $10^{-6}$ c.c./gm.) | $^3$He/$^4$He ratio (%) | Uranium (in $10^{-8}$ gm./gm.) | Thorium (in $10^{-8}$ gm./gm. |
|---|---|---|---|---|
| Beddgelert | | | | |
| Stone | 30 | — | 10·8 ± 2·7 | 39 ± 8 |
| Iron | 2·8 | — | 9·1 ± 1 | 8·5 ± 4·9 |
| Akaber | | | | |
| Stone | 14·2 | 6·3 | 0·84 ± 0·08 | 6·0 ± 2·1 |
| | | | (J. C. Dalton, private communication) | |
| Iron | Proportion of iron present in meteorite too small to permit determination | | | |
| Brenham Township | | | | |
| Stone | 3·44 | 1·0 | 0·60 ± 0·17 | 5·3 ± 2·4<br>(J. C. Dalton, private communication) |
| Iron | 0·018 | Helium content too low for mass-spectrometric determination | 0·06 ± 0·02 | < 0·7 |

In the case of stone meteorites, very few age determinations have been made by the helium method, since some terrestrial minerals have been shown to be not necessarily helium-tight (see, for example, ref. 9), and it was thus assumed that the diffusive loss of helium from stone meteorites would invalidate the method. Evidence is presented here which indicates that this effect may not be so serious as presumed. It has been suggested[8] that diffusive loss of argon from stony meteorites should not, however, be large, and for this reason it seems of especial interest to compare results obtained by the two methods.

We have extracted the helium from meteorite samples and measured the amount and helium-3 content by gas analytical techniques described elsewhere[10,11]. Very careful blank assays showed that the amount of helium contamination from the atmosphere could be reduced, in the case of irons, to 0·1 per cent of the meteoric helium measured, and, in the case of stones, to a negligible amount. Determinations of the uranium, thorium and potassium contents of t meteorites were carried out on aliquot portions of t same samples, from which portions were taken the helium and argon measurements.

In Table 1 are given the results of these determi tions, and in Table 2 are collected the apparent a of the two phases.

Other workers, using the argon–potassium meth for stone meteorites, have reported figures simi to those given in Table 2. Thus, Wasserbe and Hayden[7] report 4·6 × 10⁹ yr. for Forest C and 4·8 × 10⁹ yr. for Beardsley; Gerling a Pavlova[8] give 3 × 10⁹ yr. to 0·5 × 10⁹ yr. for so chondrites.

It may be noted that our figures for the heliu method may be slightly in error owing to the presen of cosmogenic helium in addition to the radioge helium. A correction has been made in the case Akaba and Brenham Township based on the measured content of helium-3. The ratio of helium to helium-3 formed by cosmic rays in stony materi is not yet known, and, in any event, this ratio w vary with depth within the meteorite. A value unity has been assumed in making the correction the observed content of helium-4. This is unlike to be far out, and even if the true ratio were as hi as 3, the ages quoted would have to be reduced less than 25 per cent.

It has always hitherto been considered that t helium method would probably not be reliable f stony meteorites, because of the risk of loss of heliu by diffusion. A consideration of the figures Table 2 indicates on the contrary that the loss helium may not be very serious. Thus the observ deviation between the two figures in the case of t Akaba meteorite is in fact within the statistical err of the experiment, although it may be that in t case of Brenham Township meteorite about half t radiogenic helium has been lost. In addition, t lowest age found for a stone by the helium metho is well within the range of ages found for sto meteorites by the argon method.

---

* Now at the Physics Department, University of Birmingham.

Table 2

| Meteorite | Helium method age | Argon–potassium age (ref. 8) |
|---|---|---|
| APPARENT AGES OF STONE PHASE OF METEORITES | | |
| Akaba | 3·2 × $10^9$ yr. | 3·6 × $10^9$ yr. |
| Brenham Township | 1·4 × $10^9$ yr. | 3·3 × $10^9$ yr. |
| Beddgelert | 1·2 × $10^9$ yr. | — |
| Monze | — | 1·8 × $10^9$ yr. |
| APPARENT AGES OF IRON PHASE OF METEORITES | | |
| Beddgelert | 2 × $10^8$ yr. | — |
| Brenham Township | 4 × $10^8$ yr. | — |

It therefore does appear that the two methods are substantial agreement, and that (having regard to e tendency for the helium method to err on the de of under-estimation) the true ages of stony-phase eteorites are of the order of 2–4 × $10^9$ yr. They are us of about the same age as the Earth and certainly ot older than the revised expansion-age of the iverse.

Our earlier figures for iron meteorites[4,10] have been iticized[8] on the grounds of giving too low an age. or this type of meteorite we had suggested an age about 2 or 3 × $10^8$ yr. However, it is now obvious at, by one and the same method, the age of the one phase of the meteorites described here agrees ell with the age derived by the argon method, while e iron phase is undoubtedly younger, and has an e in good agreement with our figure mentioned ove for irons.

It has been argued by Urey[8] that on thermodynamic ounds it is unlikely for the observed uranium and orium contents of meteoric irons to be correct. He ggests instead that the uranium and thorium are fact held in small stone or sulphide inclusions ithin the iron, and that the ages are falsified by cape of helium along fissures in the iron. Such a ss of helium from the bulk iron would, however, em extremely improbable, from the following perimental observations. (*a*) There is great fficulty in abstracting the helium from meteoric on *in vacuo*, even at high temperatures[12]. (*b*) urther, no fall in helium concentration with proach to the surface is observed radially in eteorites[10], and, in fact, in the only meteorite rge enough for the purpose so far available e measured concentration gradient was in the posite sense to that which would be caused by ffusive loss of helium. (*c*) Several determinations ve been made by one of us (P. R.) on each of enty different iron meteorites; samples up to gm. in weight were dissolved in dilute sulphuric id, and in only one case (Toluca (Durham), 3·7 per nt of stone by weight) was any trace of stone served after the iron had completely dissolved. is indicated that many iron meteorites have few no stone inclusions at all, and that the uranium d thorium, and hence the helium, cannot then be stulated to come from such inclusions, since, where esent, they would have to contain a far higher ncentration of uranium and thorium than occurs the bulk stony phase. (*d*) Even with the much ore friable stone meteorites, we now have evidence at helium loss is small during what appears to be much longer life-history. (*e*) No sign of such clusions, which, as pointed out above, would have contain a high concentration of uranium and orium, have been detected by autoradiographs of eteoric iron slices. Thus, it seems that the only ssible explanation of Urey's thermodynamic argu-ent is that the true thermodynamic equilibrium, as regards the distribution of uranium and thorium between the two phases, was never achieved.

There remains always the possibility of experimental error. The uranium and thorium contents of the iron phase are about ten times smaller than those of the stone. It is therefore true that a systematic error in the measurements on the stone phase might not be noticeable, whereas the same absolute error in measurements of the iron phase would be quite important. Even so, it seems that the error in the case of the iron would not be as much as a factor of 2, whereas a factor of 10 would be required to explain the difference in ages. This consideration is quite independent of arguments based on the carrying out of duplicate analyses, blank analyses, and analyses by quite different methods, all of which have been done in the attempt to eliminate systematic errors. Further, the fact that the uranium and thorium figures for the stone phase give an age in agreement with that found by the argon method is an added indication of the validity of these figures, and hence, a confirmation of the validity of the uranium and thorium contents of the iron phase, which were measured by the same methods and under the same conditions as those of the stone phase[13].

At this stage it would be as well to correct the impression given by Urey[8] that we have suggested that all iron meteorites have lost much of their helium by being heated relatively recently in a close approach to the Sun. Such an event has indeed been postulated[8] to cover the case of three meteorites of very exceptionally low helium content; but it has never been suggested for the large majority of them.

The only other experimental approach to the ages of meteorites is that of Patterson and Hayden[14], who have investigated the isotopic composition of meteoric lead, and find evidence for an age of the order of 4·5 × $10^9$ yr. for stones.

In sum, it appears to be an inescapable conclusion that the stony phase reached an evolutionary stage, after which it has lost little radiogenic or cosmogenic gas, at a period about ten times as remote from us as the corresponding period for the iron phase. If this be accepted, the hypothesis of a planetary origin for all the meteorites seems attractive, the planet having undergone a cataclysmic break-up fairly soon after the solidification of the bulk of the iron phase[15].

This would offer an explanation for the existence of (*a*) old stone-phase meteorites; (*b*) younger iron-phase meteorites which are still old enough to have been exposed to cosmic rays for sufficient time to build up their observed cosmogenic helium, and which have cooled sufficiently slowly to form their Widmannstätten figures; (*c*) chondrites, pallasites, etc., which combine the features of (*a*) and (*b*). The suggestion of pallasite formation put forward by Lord Rayleigh (1944) may well be in agreement with the results presented here, as may also be the recent suggestions of Kuiper[16], that the melting of the metallic iron in the meteorites occurred late in the history of the solar system, the melting having been produced by radioactive heating in bodies that were highly insulated. The metallurgical investigations of Uhlig[17] also seem to present evidence for the irons having been formed in the interior of a large body.

It would now seem that the range of ages suggested for stony meteoric material, from about 4·5 × $10^9$ yr. by Wasserberg and Hayden down to about 0·5 × $10^9$ yr. for the 'youngest' meteorite examined by Gerling and Pavlova, within which the present results fall, is not in serious disagreement with the range of ages for different terrestrial materials, while the younger age of meteoric irons can well fit into a general scheme of planetary evolution.

We wish to thank Prof. F. A. Paneth for providing the samples of meteorites, and for his continued interest in the work. [May 11

# A NEW METHOD FOR THE ABSOLUTE MEASUREMENT OF HIGH PRESSURES

By R. S. DADSON

Physics Division, National Physical Laboratory, Teddington Middlesex

AS part of a programme of work in the field of high-pressure physics, the National Physical Laboratory is now working on a project for the establishment of standards for the measurement of high pressures.

In practice, most measurements of high pressures intended to be of the greatest precision are made with pressure balances, or dead-weight gauges, of the familiar type in which fluid pressure acting on a piston of known area is balanced by a load applied by means of calibrated weights. The accuracy of such balances has hitherto been limited principally by the fact that at high pressures the piston and the cylinder in which it moves are distorted to an extent which is not easily measurable. As a result of this, the 'effective area' of the assembly is subject to an uncertainty which is likely to increase as the pressure is raised.

The usual method adopted in the past for the determination of the effective areas of piston–cylinder assemblies[1] has relied on the use of high-pressure mercury columns, but the results of these investigations have not so far given any clear or consistent indication of the changes in effective area under the influence of elevated pressures. A new standard mercury column of this type capable of operating up to about 2,500 atmospheres has recently been described by Bett, Hayes and Newitt[2], who discuss in detail a number of factors affecting the accuracy likely to be achieved. So far, however, no results of measurements with this instrument on actu balances have been published. While it is clear th a well-designed high-pressure mercury column capable of the establishment of high pressures wit considerable accuracy, it nevertheless seems like to be a somewhat difficult instrument to use, mainl on account of the long and laborious series of pressu transfers which need to be made to reach the hig pressure range.

The purpose of this communication is to give preliminary description of a new method for estab lishing the calibrations of pressure balances whic has recently been developed at the National Physic Laboratory. In measuring the change of effecti area of a balance as the pressure is raised, the meth makes use of a quite simple principle of similarity applied to pressure balances of the same dimensio but constructed of different materials. If we consid two piston–cylinder assemblies of the same nomin dimensions but of materials the elastic constants which differ in a known ratio, then in certain circum stances, considered in more detail below, the di tortions, under applied pressure, of the two assembli will remain proportional to one another througho the range of pressure concerned. Under these con ditions, and neglecting small quantities of the secon order, we may represent the effective areas $A$ and of the two assemblies at a given pressure in the for

$$A = A_0\{1 + \alpha.\mathrm{f}(P)\}\,;\quad B = B_0\{1 + \beta.\mathrm{f}(P)\}.$$

In these expressions $A_0$ and $B_0$ are the (nominall equal) effective areas at zero pressure, $\alpha$ and $\beta$ a constants inversely proportional to the elastic modu of the two materials, and f($P$) is an unknown functio of the pressure, $P$. The ratio of the two effectiv areas will be given, to the same order, by th expression

$$A/B = A_0/B_0\{1 + (\alpha - \beta).\mathrm{f}(P)\}.$$

This ratio is easily determined by balancing the tw assemblies directly against one another, and th procedure determines the quantity $(\alpha - \beta).\mathrm{f}(P$ The quantity $\alpha/\beta$ may be obtained from direc measurements of the elastic constants of the tw materials. These two procedures thus enable th absolute value of the change of effective area of eac of the piston–cylinder assemblies to be determined

For the theory outlined above to be valid, number of conditions must be satisfied, both a regards the materials and the construction of th assemblies. Since two independent elastic modu will be involved in a somewhat complicated manne in the distortion of each assembly, true proportion ality can only be achieved if both moduli are in th same ratio—in other words, the values of Poisson' ratio for the two materials should be closely simila As regards construction, the forms of the interna bores of the cylinders, and of the pistons, must b closely similar in contour, since otherwise the dis tributions of pressure in the gap between piston an cylinder will not be the same in the two assemblie The similarity principle also requires that the gap widths at zero pressure should be inversely pro portional to the elastic moduli. If these condition are adequately met, and the elastic properties of th materials are uniform throughout the range of stres involved, proportionality of the distortions will b assured. This will remain valid even if the viscosit of the transmitting fluid is dependent on pressure, a will almost certainly be the case. It is, however worth noting that the effective area of a pressur

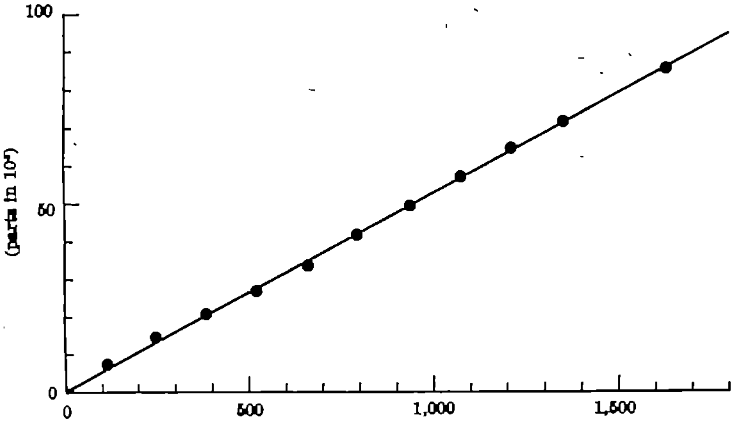

Fig. 1. Dependence of effective area on pressure for steel piston–cylinder assembly of nominal area 0·02 sq. in.

alance may depend to some extent, at high pressures, n the viscous properties of the fluid used.

The present series of experiments at the National hysical Laboratory is intended to cover the range p to 3,000 atmospheres. The two materials so far sed are a hard tool steel and a special type of bronze f high tensile strength. The strains of the materials aded in tension, compression and shear have been easured over the range of stresses imposed in the ressure experiments. Within the limits of accuracy f these measurements, the stress–strain relationships ere linear and conformed to a fixed ratio of the astic moduli of 1·44 : 1. Measurements in three irections at right angles which were made by the ltrasonic-wave velocity method, using longitudinal nd shear waves, indicated the materials to be satis- ctorily isotropic. The accuracy of construction of e assemblies is largely limited by the accuracy with hich the cylinder bore can be made and measured. wing to recent improvements which have been ade in the Metrology Division of the Laboratory the measurement of the form and diameters of ylinder bores[3], it has proved possible to construct iston–cylinder assemblies to the requisite precision, nd with the required degree of similarity.

The results of the present series of measurements ow that the method is capable of a very satisfactory egree of accuracy and consistency, and permits the easurement of the variation in effective area over wide range of pressure to within a few parts in $10^5$ f the total area. In fact, over small ranges of ressure, variations in effective area of only a few arts in $10^6$ of the total area can be determined. An ample of the results obtained is shown in Fig. 1, here it will be seen that a particular steel piston– ylinder assembly of nominal area 0·02 sq. in. may ange in effective area by an amount of the order part in 2,000 per 1,000 bars of applied pressure. In is instance the change proved to be a linear function f pressure to the order ± 1 part in $10^5$ of the total rea.

While the present series of tests is intended to over the range up to 3,000 atmospheres, plans are eing made to extend this range to higher pressures o far as may be practicable, and some further teresting possibilities of the similarity method are nder investigation. Full details of this work will be ublished in a further paper. From the nature of e method it seems that it should be applicable over irtually any range over which pressure balances can be used, and in which two materials having the necessary properties are available. The main difficulty in the method resides in the construction of the highly accurate pistons and cylinders which are required. Once these are available, the experimental work in determining the variation of effective area is simple, quick and convenient.

We have so far dealt only with the variation in effective area with pressure, but at some point of the scale the effective area must be measured in absolute terms. This link is most easily made at a low pressure where distortion is known to be negligible. The present procedure at the National Physical Laboratory is to use two independent methods to obtain this measurement: (*a*) direct measurement by balancing at a low pressure against a mercury manometer; (*b*) by computing the effective area from the measured dimensions of the piston and cylinder.

These two methods of measurement have given agreement to within 2 parts in $10^5$; but it is thought that this accuracy can be somewhat improved.

I acknowledge the helpful co-operation of the Metrology Division of the Laboratory, which undertook the measurement and construction of the special piston–cylinder assemblies required, and of the Engineering Section of the Physics Division, which determined the elastic constants of the materials.

The work described was carried out as part of the research programme of the National Physical Laboratory, and this communication is published by permission of the Director of the Laboratory.

# THE COMMONWEALTH MYCOLOGICAL INSTITUTE

By Dr. S. P. WILTSHIRE

Director

THE opening of the new building of the Commonwealth Mycological Institute at Kew by H.R.H. the Duke of Edinburgh on July 13 was a notable event in the history of the Institute. Founded in 1921, the Institute first occupied two houses, 17–19 Kew Green, but in 1930 moved to a building in Ferry Lane, erected with the help of the Empire Marketing Board. That building rapidly proved inadequate and plans were prepared for an extension of it to be put before the Commonwealth Mycological Conference arranged for September 1939, but which had to be abandoned owing to the outbreak of war. Since 1939 the work of the Institute has increased enormously, and the Fourth Commonwealth Mycological Conference, held in 1948, recommended the immediate erection of a new building. The freehold site on which the new building stands became available and was purchased in 1950 through the prompt action of the chairman of the Executive Council. Detailed plans were put before the Commonwealth Agricultural Bureaux Review Conference in 1950 and approved; but the cost was to be borne on a separate vote. Administrative difficulties arose and the funds for the building were not sanctioned until 1953. Building operations started in May 1954, and were just completed in time for the opening. The lack of accommodation has been most seriously felt; but the new building now erected to the plans of Messrs. Waterhouse and Ripley affords adequate and most suitable quarters.

The need for additional space may be judged from the fact that the staff of the Institute now numbers thirty-seven and includes ten mycologists covering the editorial and identification services, including the culture collection, six abstractors, five of whom are linguists covering most of the languages in the literature of the subject, a herbarium recording staff of three, an indexer-librarian and five technical assistants, besides clerical staff. In addition, there is a pool of three plant pathologists attached to the Institute by arrangement with the Colonial Office, which provides the necessary finance. These plant pathologists undertake research into the cause and control of disease in the Colonial dependencies when required and may be moved to danger spots at short notice.

In his address, the Duke of Edinburgh stressed the importance of plant disease control in increasing and maintaining agricultural production. The spear-head of the attack on plant disease is, he emphasized, research, and the fight is seldom once and for all. New diseases or new variations of old diseases are always cropping up. Plant diseases could have disastrous effects not only on the economy but also on the social pattern of a country. The Institute has the important task of making it easier for research workers to follow what is going on elsewhere and to avoid duplication of effort. Much is heard, he said, of the invisible links of the Commonwealth, but this is one of the tangible ones. He was glad to find it possible for Commonwealth countries to co-operate in this particular field, and he hoped everyone who works at the Institute would find it a rewarding occupation.

The building is in the Georgian style to fit in with the surrounding architecture. The ground floor is devoted wholly to the library, apart from a small room for the Director. The literature of plant pathology and mycology increased enormously during the Second World War, and as one of the main functions of the Institute is to abstract this information for its journal, the *Review of Applied Mycology*, adequate library accommodation is absolutely vital for its work. The opening ceremony took place in this spacious room, which in due course is to be fitted with the requisite shelving and furniture. The room is well lit by fifteen windows, and tables are to be provided for fifteen readers. For several years the purchase of journals has had to be limited from lack of space, and the need for reprints of plant-pathological and mycological articles published in past as well as recent years, especially from foreign countries, is very great. The library of the Institute should be one of the best phytopathological and mycological libraries in the world, and the co-operation of all plant pathologists is earnestly sought in supplying or making available the necessary literature. The collection of 'separates', now numbering some sixty thousand pamphlets, is to be inco porated in the library.

Besides the *Review of Applied Mycology*, th Institute publishes distribution maps of plan diseases, the "Index of Fungi", listing all new specie of fungi described throughout the world, the *Revie of Medical and Veterinary Mycology*, surveying th world's literature on this subject, *Mycological Paper* recording the results of research in systemati mycology, and the quarterly *Commonwealth Phyt pathological News*. The Institute has also issue several books, the best known being the "Diction ary of Fungi", by G. C. Ainsworth and G. F Bisby.

The first floor of the new building accommodate the herbarium of the Institute, which now contain about 65,000 collections. The identification servic maintained for the benefit of Commonwealth plan pathologists and mycologists, is the other majc activity of the Institute. From the start, th Institute has recognized that investigations into th etiology of plant diseases can only be made by plan pathologists working in the countries where th diseases occur; and on the other hand, the identi fication of the pathogens can only be carried out b trained systematists working in a herbarium witl adequate literature and specimens available. Th identification of fungi is difficult work and require special qualities and prolonged training. Mr. E. W Mason, chief mycologist, has developed a herbarium technique which is both unique and valuable an has built up an enthusiastic staff for this arduou task. For years the staff employed in the work hav been greatly hampered by overcrowded conditions In the new building, the main herbarium runs th whole length of the building, with the exception of room for the chief mycologist. Rooms are also pro vided on the south side for herbarium records, drying room where specimens can be dried for th herbarium, a culture room, and a disinfestation room where all incoming material is disinfested from beetles and other insects with methyl bromide Fluorescent lighting enables the herbarium cases t be placed in rows, with a resultant great saving o space.

The top floor comprises four rooms for visitors with eight working benches, and two large rooms fo the culture collection, one a preparation room, an the main laboratory occupying the whole of the fa end of the building. The collection now comprise upwards of two thousand cultures and is constantl being added to. Adequate storage cabinets designe for the work, incubators, cupboards, desks an benches make the laboratory a well-equipped an pleasant room for culture work. Special cabinets fo making transfers have not been found necessary an are not incorporated in the new laboratory, with corresponding saving in cost.

The basement runs the whole length of the buildin and provides accommodation for photographic dark rooms, comprising two developing rooms, one studi and one microfilm room, storage room for pub lications, the boiler with space provided for a secon boiler should the building ever be extended, a work shop, and a room for electric and gas meters. Th building is constructed of reinforced concrete witl hot-water pipes embedded in the floors, thermo static control and automatic firing of the boiler, an provision for the mechanical delivery of the fue from suitably constructed lorries. The plans provid for an extension of the building to double its presen e should this be required, and the internal walls n readily be removed without damage to the ructure if a rearrangement of the rooms should ove desirable in the years to come.

The old building is being retained to house the lministration and editorial and abstracting staffs, id one room is set apart for the pool of plant thologists when they happen to be working in reat Britain.

# OBITUARY

## Dr. Bernard J. Flurscheim

DR. BERNARD J. FLURSCHEIM, who died recently t his home in Fleet, was in his eighty-first year. So asses the last of the great pre-electronic builders of e theory of organic chemistry.

After a school education on classical lines at Baden nd Bournemouth, Flurscheim made his first scientific udies in the University of Geneva; afterwards he orked with Werner in Zurich, and with Thiele in trassburg. He took his Ph.D. degree in Heidelberg 1901. In 1905 he set up his house in Fleet, in the arden of which he built the laboratory, where he orked, until other duties claimed him in the First Vorld War. For the periods 1905–7 and 1925–28 he orked in the Royal Institution in London.

In his main scientific work, the provision of rganic chemistry with a theoretical framework, lurscheim was natural successor to both Werner nd Thiele: he started from Werner's ideas of the ivisibility of chemical affinity when discussing its istribution on molecules, and it ranks as a major nd lasting discovery that his schemes of distribution ivolve a generalization of Thiele's theory of conigation, as is to-day so readily appreciated in elecronic terms.

Flurscheim's first paper of classical importance, ublished in the *Journal für praktische Chemie* in 1902, described the first rational explanation of orientation in aromatic substitution. In 1909–10 he published in the *Journal of the Chemical Society* two papers of like importance on the strengths of acids and bases. Here he was extending the application of his theory from the kinetic to the thermodynamic field, thereby showing that his valency redistributions apply not only to activated states but also to normal molecules. To-day, with the aid of the quantum theory, we re-express this, too, in electronic terms, and call the result mesomerism or resonance.

Flurscheim published many other papers of more limited importance. He never participated in the remoulding of his theories in conformity with the electronic theory of valency and quantum mechanics. However, the largely correct form of Flurscheim's theories made this task of recasting them a particularly easy one for others.

His discovery of tetranitroaniline, perhaps the most powerful of known explosives at the time of its discovery, was an accidental result of his work in the Fleet laboratory, directed as this was to the experimental control of his theoretical ideas. It was an accident that he sometimes regretted, inasmuch as it led him into commercial work, to which he was not well suited. However, it enabled him to render notable service during the First World War, when, on the request of the late Lord Moulton, he undertook supervision of the large-scale manufacture of this explosive in the United States. During the Second World War he worked as gas identification officer for the A.R.P. authorities.

Flurscheim did not make human contacts easily or treat them lightly. He was devoted to his family, and to a few firm friends. His chief personal hobbies were travel and climbing. In 1903 he visited New Zealand, where his father, Michael Flurscheim, lived, and there made acquaintance with the New Zealand Alps. He knew the Alps of Europe very well. He leaves a widow, a daughter and a son.

C. K. INGOLD

# NEWS and VIEWS

### hemistry at University College, London: Prof. D. P. Craig

A NEW chair of chemistry at University College, ondon, has been instituted, and Prof. D. P. Craig, f the University of Sydney, is to be its first occupant. Ie will take up the duties of the chair in 1956. Prof. raig took his first degree with first-class honours in hemistry in 1940 in the University of Sydney, where e remained as Commonwealth Research Fellow until 942. During 1942–44 he served with the rank of aptain in the Australian military forces. In 1946 he vas appointed lecturer in chemistry in the University f Sydney, and during 1946–50 he was Turner and Newall Fellow in the University of London, being ppointed lecturer in chemistry at University College, ondon, in 1950; since 1952 he has been professor f physical chemistry in the University of Sydney. Prof. Craig's research career is that of an experimental physical chemist with deep knowledge of, nd interest in, the theory of chemistry. He has ublished work on co-ordination compounds with articular reference to the nature of metal-ligand onds, on aromatic character and the conditions or its appearance, on the excited states of unsaturated and aromatic molecules, on the excited states of crystals, and on the relation between molecular and crystal states. He has also contributed to the methodology of quantum mechanics by introducing configuration interaction into molecular orbital theory, and clarifying the role of polar structures in valency-bond theory. The addition of so accomplished a theoretician to the Chemistry Department of University College, where co-ordination chemistry, molecular spectroscopy and crystal chemistry are all intensively studied, seems particularly appropriate.

### Sir William Hamilton (1805–65)

ONE of the most brilliant mathematicians of modern times, William Rowan Hamilton was born in Dublin one hundred and fifty years ago, at midnight between August 3 and 4, 1805, of a Scottish family that had settled in Ireland. He was a precocious child, being able to read Hebrew at the age of seven; at twelve he had mastered Latin, Greek and the leading Continental languages, and had acquired some knowledge of Syriac, Persian, Arabic, Sanskrit, Hindustani and Malay. Quite early he showed his genius for mathematics, and in his seventeenth year detected an error of reasoning in Laplace's "Mécanique céleste". At Trinity College, Dublin, he was first in all his examinations and, while still an undergraduate, he predicted in 1833 by the aid of mathematics the internal conical refraction of light, which was verified experimentally in the same year by H. Lloyd. Hamilton was then appointed John Brinkley's successor in the chair of astronomy; he later became Astronomer Royal for Ireland. From 1843 onwards Hamilton devoted his life to the elaboration of his theory of quaternions, which was announced in "Lectures on Quaternions" (1853) and posthumously in "Elements of Quaternions" (1866). As a writer he was sometimes obscure and metaphysical, but he excelled as a fluent and ornate lecturer. He was knighted in 1835, was elected president of the Royal Irish Academy in 1837, and died on September 2, 1865, at the age of sixty, worn out physically and mentally.

## Shortage of Scientific Workers and Teachers in Great Britain

IN a debate in the House of Lords on July 5 on exemption from National Service, Lord Cherwell pressed again for the exemption of highly trained scientific workers, especially those engaged in high-grade research in the universities. Lord Cherwell suggested that there was great lack of balance in limiting deferment to fifty such scientists in a year when eight thousand agricultural workers are deferred each year; but Lord Carrington, replying for the Government as Parliamentary Secretary to the Ministry of Defence, stated that the Government has not yet received fifty applications from the universities for deferment under this scheme, and thought that it is much too early to judge how well this scheme, introduced earlier this year, is working. Lord Carrington also referred to a scheme, introduced since 1949, under which science and engineering graduates have been deferred for employment on a limited number of research and development projects mostly connected with the defence programme; and he emphasized the need of the Armed Services for technical graduates, particularly for younger workers with degrees in engineering, physics and mathematics. It has been estimated that in 1955 the Services will recruit less than half their requirements, and graduates in science are also badly needed by the education branches of all three Services for teaching in technical training colleges.

The debate was thus related to an adjournment debate in the House of Commons later in the week on the shortage of science teachers—a matter to which Lord Cherwell also referred, as did Lord Hull and Lord Glyn, whose purpose in tabling the motion was to emphasize the importance of giving technical and technological education and research a very high place in the affairs of the country. In raising this question in the Commons on July 8 and asking the Government what steps it proposes to take to meet the shortage, Dr. Horace King supported the exemption of science teachers from national service, or at least the exemption of those who had completed their initial or basic training, and Mr. E. C. Willis pointed out that the Appleton Committee had recommended the exemption of teachers with first- or second-class honours in mathematics, physics or chemistry, as being the only sure means of getting more teachers quickly. In replying for the Government, Mr. Dennis Vosper, Parliamentary Secretary to the Ministry of Education, declined to discuss th question of deferment; he pointed out that th teaching profession itself is divided on the question that deferment would make a comparatively smal contribution to the removal of the shortage, and tha it would involve a breach in the principle of universality. He did not think that too much importanc should be attached to the proposal in trying to solv the larger problem. Mr. Vosper said that the presen shortage of science teachers is less than expected recruitment having exceeded the forecast; durin the period March 1952–March 1954, the number o graduate science and mathematics teachers in maintained primary and secondary schools in Englan and Wales increased from 11,022 to 11,615. Th main difficulty is in quality, and the real gravity o the problem was in the anticipated increase of 650,00 in the number of senior pupils by 1960 compare with 1954, with the consequent demand for a furthe 3,200 graduate science teachers. Mr. Vosper referre to the possibility of making conditions of servic more attractive for teachers of science and mathematics, and said that the Minister hopes shortly t advise local education authorities as to the possibilit of paid leave to teachers to take part in research but he thought that the real solution to the shortag lies in a change in the public esteem of the teachin profession and an increasing public awareness of th needs of science.

## Personnel Research in the Royal Navy

THE record during the Second World War of th Royal Navy's concern with the safety and efficiency of its personnel can be found in the volume o medical research in the "Official Medical History o the War" (1953). In the post-war period the alliance between the Navy and the Medical Research Council in this field of research has continued vigorously and fruitfully. An up-to-date survey of naval personnel research (Admiralty Bulletin 67, pp. 12; Department of Chief of Naval Information, Admiralty, London, S.W.1; 1955) has now been written by Surgeon-Commander Crosfill, the present secretary to the Royal Naval Personnel Research Committee. The survey is a record of progress both in occupational hygiene and that branch of operational research for which the name ergonomics has been coined and which is concerned with the efficiency of the operator in his working environment. Commander Crosfill gives an informative and readable account of the important work sponsored by the various sub-committees of the main Committee. It is quite clear that the *ad hoc* work has nearly always been based on, and been a fruitful source of, much fundamental investigation. This is evident, on the psychological side, in studies of multi-channel communication, of various kinds of pressure and velocity control systems, and the effects of noise, all of which raise fundamental questions of vigilance, perception, proprioceptive 'feed-back' and skill. On the physiological side, studies of working efficiency in abnormal climates have yielded a great deal of basic data on human heat regulation, acclimatization and limits of heat tolerance and have led to improvements in the design of climatological 'indices' and the introduction of the ionization anemometer. Perhaps the most spectacular of the investigations is that sponsored by the underwater physiology sub-committee in connexion with the problem of submarine escape. This work has led to the development of the technique of escape by 'free ascent', and has made a breathing set unnecessary. Other interesting topics in the report are concerned with survival at sea, nutrition in the arctics and the tropics, anatomical problems of seating and sighting, and the use of standardized photographs for the anthropometry of naval personnel.

## Hydraulics Research Station, Wallingford : Report for 1954

THE report of the Hydraulics Research Board for 1954, with which is published the report of the Director of Hydraulics Research (pp. 52+11 plates. H.M.S.O., London, 1955; 5s. net), summarizes the work on loose-boundary hydraulics done at the Hydraulics Research Station, Wallingford, Berks. The greater part of it is concerned with ten model investigations and field studies of estuaries, river improvement schemes, and dock and harbour modifications, carried out at the request of various official bodies. Of fundamental work of more general application, there is at present comparatively little; but comments at various points in the report suggest that experience gained from these miscellaneous investigations is gradually indicating the directions in which more general research should be pursued. Topics in which work has already begun include the use of radioactive tracers for indicating the movements of silt or mud, the determination of the effect of wind on wave propagation, and a study of the factors affecting cyclic channel movements in an estuary and the development of meanders. The report generally is of the high standard of presentation and lucidity that one expects from a technical publication of the Department of Scientific and Industrial Research; but a more distinctive grouping of the various topics covered in it would make for an easier appreciation of the range of interests and activities of the Research Station.

## Measurement of Pressure with the Mercury Barometer

No. 9 in the series "Notes on Applied Science", of the National Physical Laboratory, Teddington, is entitled "Measurement of Pressure with the Mercury Barometer" (pp. 15+1 plate. London: H.M.S.O., 1955; 1s. net). Reference is made to the new rationalized system of barometer conventions which came into operation on January 1 (see *Nature*, 174, 1127 (1954), and British Standard 2520); but the main purpose of the pamphlet is to assist those workers in industry and in research laboratories who are concerned with the measurement of gas pressures by means of a mercury column. Pressures in the range 0–1,200 millibars are dealt with, and the accuracy considered is of the order of ± 0·1 millibar. The fundamentals of pressure measurement are briefly outlined, and then the two main categories of barometers, the Fortin and Kew types, are described, together with the factors which should be considered in choosing a barometer for a particular application. Valuable advice as to the proper methods of transport, storage and installation of barometers is given, and the observational procedure to be adopted and the various corrections to be applied to the readings taken are discussed and illustrated by a particular numerical example. Finally, a short description is given of the testing procedure followed at the National Physical Laboratory. This includes an illustration of the Laboratory's primary standard barometer, which is nearing completion.

## A Mobile Bone Meal Factory in Africa

THE deterioration of African livestock shown by lack of productivity, poor calves and lack of resistance to parasitic infestation is in large measure due to insufficient phosphorus in the diet. No matter how excellent the animal husbandry practices may be, that is, rotational grazing, manuring and water supply, full response cannot be expected without making good the deficiencies of calcium and phosphorus. Phosphorus deficiency is a fundamental environmental factor which cannot be remedied otherwise than by supplementation of phosphorus. A mineral survey of Kenya soil, pasture and beasts has shown that in most cases there is a phosphorus deficiency. This deficiency may be made good, either in part or completely, by using mobile bone meal factories as envisaged by Dr. I. Mann (*Colonial Plant and Animal Products*, 4, No. 4). These will make available on the spot substantial quantities of cheap phosphorus in the form of sterilized bone meal. The low capital expenditure necessary is entirely out of proportion to the benefits accruing to man and beast. Bones become a new and valuable cash crop, while the product offers the African the opportunity of improving his primitive husbandry and of rearing healthy and more productive livestock.

## Factors in Clover Nodulation

THE effect of certain adsorbents on the nodulation of clover plants has been investigated by E. R. Turner (*Ann. Bot.*, N.S., 19, 147; 1955). He has found that the addition of charcoal to the rooting medium of clover plants, inoculated with effective and ineffective strains of *Rhizobium*, leads to a stimulation in nodule production. The time-interval between inoculation and the first appearance of the nodules is reduced in the presence of charcoal. The author concludes that this stimulation is due to the adsorption by the charcoal of inhibitory compounds secreted by the clover roots. These compounds have, in fact, been eluted from the charcoal and have been shown to affect nodule production. It is suggested that, according to the concentration of the secretions in the eluates, either a stimulation or an inhibition of nodule formation may occur.

## Biochemical Synthesis and Isotopic Tracer Technique

A GOOD many monographs have appeared in recent years on the use of isotopes as tracers to find how the body builds up complex materials from the breakdown products of the food. Dr. G. Popják, in a recently published lecture entitled "Chemistry, Biochemistry and Isotopic Tracer Technique" (Lectures, Monographs and Reports of the Royal Institute of Chemistry, London: No. 2, 1955; pp. 59), discusses the way in which the techniques of organic chemistry and of enzymology have been linked with the tracer technique in such work. Instead of trying to cover the whole field, Dr. Popják deals mainly with certain major topics—namely, fatty acids, cholesterol and the porphyrins—and discusses them in sufficient detail to show the interdependence of the three methods of approach in throwing light on the problems of biochemical synthesis. He underlines the need for continued close collaboration between the organic chemist and the biochemist in work of this type.

## Museum Uses of 'Perspex'

IN the May number of the *Museums Journal*, Mr. R. A. Kennedy details two further uses for 'Perspex' in museum work. When this substance is used as a protective covering for labels, it is found that in course of time dust accumulates between the card and the 'Perspex', and periodical removal and cleaning are a time-wasting process of little permanent value. A more satisfactory result is obtained by using 'Perspex' liquid cement containing chloroform to seal the label, and Mr. Kennedy gives practical details for doing this. The second use is for the reproduction of flint tools. It was found that 'Perspex' flakes in a similar fashion to flint when kept cold or, even better, when chilled. It is thus only necessary to use 'Perspex' of the correct colour, and by a combination of cutting out, filing, flaking and scraping an excellent imitation of a flint implement can be obtained.

## Technical Hardness Measurement: International Conference in Bremen

An international conference on "Hardness Measurement in the Works" will be held in Bremen during September 22–23, in connexion with an exhibition there of modern hardness-measuring equipment of German and foreign manufacture. It is the second to be held in Bremen and is being arranged by the Arbeitsgemeinschaft fur Fertigungstechnisches Messwesen (Working Committee for Metrology in Production) and the Institut für Härteprüftechnik (Institute for Hardness-testing Technology). At the conference, representatives from Austria, France, Germany, Great Britain, Japan and the United States will discuss actual problems of hardness measurement according to Rockwell, low-load and micro-hardness measurements after Vickers, hardness measurement on internal surfaces, as well as the possibilities and advantages of using technical statistics in the field of hardness testing. It is hoped to contribute to the establishment of internationally comparable hardness values, which are of much importance for technical products. Further details regarding the conference can be obtained from AFM, Verein Deutscher Ingenieure, Prinz Georg Strasse, Düsseldorf, Germany.

## Association of Universities of the British Commonwealth

A Commonwealth Inter-University Conference will be held in Melbourne, Australia, during August 9–12, comprising the members of the Executive Council of the Association of Universities of the British Commonwealth, which holds an overseas meeting in the years between its quinquennial congresses. Similar meetings have recently been held in Canada (1949 and 1954), New Zealand (1950) and India (1951–52), but this is the first to be held in Australia. These conferences, which have been supported very generously by the Nuffield Foundation, provide the opportunity for discussion of matters of academic policy and Commonwealth inter-university relationships. The present meeting is to be presided over by Mr. A. P. Rowe, vice-chancellor of the University of Adelaide, and chairman this year of the Association of Universities of the British Commonwealth, and each Commonwealth country will be represented by one or more university executive heads, the United Kingdom party comprising Dr. R. S. Aitken (Birmingham), the Right Hon. H. U. Willink (Cambridge), Dr. D. W. Logan (London) and Mr. C. H. Wilson (University College, Leicester). The secretary of the conference is Dr. J. F. Foster, secretary of the Association of Universities of the British Commonwealth. The conference members while in Australia will visit other universities ther and will attend the inauguration ceremonies of th new University of New England at Armidale, Nev South Wales, on August 4.

## University of London

The title of professor emeritus in the Universit of London has been conferred on the following Prof. J. H. Dible, on his retirement from the chai of pathology at the Postgraduate Medical School o London; Prof. Herbert Dingle, on his retiremen from the chair of history and philosophy of scienc at University College; Prof. V. C. Illing, on hı retirement from the professorship of geology (o technology) at the Imperial College of Science an Technology; Prof. H. H. Read, on his retiremen from the chair of geology at the Imperial College o Science and Technology.

The title of reader in botany in the University o London has been conferred on Sir Nigel Ball, Bart. in respect of his post at King's College, and that o professor of physics in the University of London o Dr. W. C. Price, in respect of his post at King' College.

The following appointments in the Universit have been announced: Prof. J. Duchesne, directo of the spectroscopic radio-electric laboratory i the University of Liège, to the visiting professorship of Belgian studies in the University of Londo for a period during the second and third terms of th session 1955–56; Dr. Geoffrey Wilkinson, assistan professor of chemistry at Harvard University, to th University chair of inorganic chemistry tenable a the Imperial College of Science and Technology Dr. W. G. Overend, lecturer in chemistry in th University of Birmingham, to the University readership in organic chemistry tenable at Birkbeck College Dr. W. S. Pitcher, lecturer at the Imperial Colleg of Science and Technology, to the University readership in geology tenable at King's College.

## University of Leeds

The following appointments in the University o Leeds have been announced: Mr. D. C. Johnson, to be professor of mechanical engineering from January 1, 1956; Dr. D. Bradley, to be lecturer in mechanical engineering; Dr. D. A. Jones, to be lecturer in electrical engineering; Mr. S. C. Mitchell, to be lecturer in fuel technology; Dr. J. H. Robertson, Brotherton lecturer in the Department of Inorganic and Structural Chemistry, to be lecturer in the Department of Inorganic and Structural Chemistry; Mr. T. Wilson, to be lecturer in electrical engineering.

The University has acknowledged the following gifts, among others: £300 from the Yorkshire Agricultural Society, for the Department of Agriculture; £700 from Messrs. Joseph Booth and Brothers, Rodley, for the Department of Civil Engineering, to maintain a student for two years to undertake research work on the dynamic stresses induced in cranes; £3,000 for 1954–55 from the North-Eastern Division of the National Coal Board, for the Department of Mining; £940 from the Royal Society, for the Department of Physics, for research carried out by Dr. R. S. Tebble on the magnetic properties of metals and alloys at high temperatures.

## Salters' Institute of Industrial Chemistry: Awards

The Salters' Company has elected M. J. Stephen to be a Salters' Fellow for the year 1955–56. Mr. Stephen, who is a graduate of the University of the

Witwatersrand, Johannesburg, obtained an M.Sc. degree in 1953 and is at present studying for the degree of D.Phil. under Sir Cyril Hinshelwood at Oxford. During the coming year he will carry out research under Prof. C. A. Coulson, at Oxford, on the mechanisms and rates of reactions. The Salters' Company has offered a scholarship to a student from Canada, and, on the recommendation of the National Research Council for Canada, C. G. Miller, of Queen's University, Ontario, has been appointed; Mr. Miller will carry out research during the year of tenure of his scholarship under Mr. R. P. Bell, of the University of Oxford. The Court of the Company has also elected the following to be Salters' Scholars for the year 1955–56: M. McLeman (Imperial College, London); W. L. Wilkinson (Cambridge); D. Charlesworth (Hull); P. L. Levine (Imperial College, London); D. M. McMahon (Queen's University, Belfast); W. Kemp (Glasgow); B. B. Hunt (Cambridge).

## Colonial Service: Recent Appointments

The following appointments have been made recently in the Colonial Service: J. H. Gisborne (principal agricultural officer, Northern Region, Nigeria), assistant director of agriculture (research), Northern Region, Nigeria; T. N. Greeves (deputy director of agriculture, Sierra Leone), director of agriculture, Sierra Leone; T. S. Jones (senior agricultural officer, Sierra Leone), deputy director of agriculture, Sierra Leone; M. A. Blane and F. A. Leeds (senior agricultural officers, Gold Coast), assistant directors of agriculture, Gold Coast; C. R. Dickson, J. T. W. Gray, R. Mulholland, J. H. N. Pitman, W. Smith and T. M. Wiszniewski (agricultural officers, Gold Coast), senior agricultural officers, Gold Coast; P. Peterson (meteorological officer, Singapore), scientific officer, Royal Observatory, Hong Kong; W. G. G. Forsyth (principal scientific officer, Colonial Microbiological Institute, Trinidad), director of the Colonial Microbiological Institute, Trinidad; C. Turner, agricultural officer, Kenya; K. A. Exelby, chemist, Government Chemist Department, Tanganyika; D. McKie, mineralogical chemist, Tanganyika; R. N. Cope, geologist, Federation of Nigeria; J. R. Baker, scientific officer (protozoologist), East African Tsetse and Trypanosomiasis Research and Reclamation Organization; W. N. Beesley, scientific officer (parasitologist), Helminthiasis Research Unit, Kumba; P. E. S. Whalley, entomologist, Uganda; P. J. S. Anderson, veterinary officer, Tanganyika; A. T. Carey, assistant adviser on aborigines, Federation of Malaya.

## The Night Sky in August

Full moon occurs on Aug. 3d. 19h. 30m., U.T., and new moon on Aug. 17d. 19h. 58m. The following conjunctions with the moon take place: Aug. 19d. 0h., Mercury 7° N.; Aug. 24d. 04h., Saturn 5° N. Mercury is too close to the sun for observation during August. Venus, which rises about forty-five minutes before sunrise up to the middle of the month, rises almost at the same time as the sun at the end of the month, and is unfavourably placed for observation during August. Mars, in conjunction on August 17, cannot be observed during the month. Jupiter, in conjunction on August 4, is visible towards the end of the month when it rises about two hours before the sun, and can be seen in the constellation Cancer, in which it has an eastward movement. Saturn sets at 23h., 22h. and 21h. on August 1, 15 and 31, respectively; its eastward movement can be detected by comparing its positions at various times with the second-magnitude star α Librae from which it is receding. Its stellar magnitude varies from 0·7 to 0·8, the diminution in brightness being due to the increase in its distance from the earth by forty-five million miles. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: Aug. 6d. 01h. 18·4m., κ Aqr. (*R*); Aug. 7d. 01h. 56·8m., κ Psc. (*R*); Aug. 12d. 03h. 18·9m., *A* Tau. (*D*); Aug. 29d. 22h. 32 4m., 57 Sgr. (*D*). *D* and *R* refer to disappearance and reappearance, respectively. The Perseid meteors attain a maximum about August 10–13; moonlight will interfere to some extent with observations during that period.

## Announcements

Dr. A. Neuberger is resigning from the chairmanship of the Editorial Board of the *Biochemical Journal* on October 1, and will be succeeded by Dr. A. G. Ogston. The editorial office of the *Journal* will be transferred from the National Institute of Medical Research at Mill Hill to the Lister Institute of Preventive Medicine, Chelsea Bridge Road, London, S.W.1, as from September 1. Communications should be addressed from that date to Mr. F. Clark, secretary to the Editorial Board, *Biochemical Journal*, at the Lister Institute.

A symposium on "Cavitation in Hydrodynamics" will be held at the National Physical Laboratory, Teddington, Middlesex, during September 14–17. Attendance will be by invitation, and those interested are asked to communicate with the Director of the Laboratory.

The Universities Federation for Animal Welfare is holding its summer school this year at Westham House, Barford, Warwick, during September 24–October 1. There will be expeditions to a dairy farm, Dudley Zoo and a slaughterhouse, and lectures by experts on the following topics: animal behaviour, animals in zoos and circuses, slaughtering methods, animals in research, dairy husbandry and whaling. The fee for the school is five guineas (three guineas for students). Further information can be obtained from the Branch Organizer, UFAW, 7*a* Lamb's Conduit Passage, London, W.C.1.

The July–September 1953 number of the "Bibliography of Articles appearing in Turkish Periodicals", issued recently by the Turkish National Institute of Bibliography, Istanbul (pp. 116. Istanbul: Maarif Basimevi), contains a further seven hundred entries given, as previously, in French and Turkish and arranged under the first two figures in the Decimal Classification. Entries are limited to title, author and reference. There are an author index and a list of periodicals covered.

A report of the proceedings of the 1954 Conference of the Universities of Great Britain and Northern Ireland, held in London during December 17–18, 1954, is now conveniently available in pamphlet form (pp. 110. London: Association of Universities of the British Commonwealth; 1955; 2*s*. 6*d*.). It includes the text of the speeches of Dr. E. J. F. James and Prof. R. E. Peierls at the important discussion on the supply of teachers for mathematics and science, those of Mr. J. F. Wolfenden and Prof. H. S. W. Massey at that on whether undergraduate courses of study are overloaded, and of H. R. F. Harrod and Prof. J. F. Baker in opening the discussion on the retiring age for university teachers.

# BRITISH FOOD MANUFACTURING INDUSTRIES RESEARCH ASSOCIATION

## OPEN DAY

THE fine modern laboratories of the British Food Manufacturing Industries Research Association at Leatherhead, Surrey, were occupied in the latter part of 1950, and the opening ceremony performed in November of the following year was then made the occasion of an open day[1]. On June 21 last the laboratories were once again thrown open to representatives of member firms, while representatives of other research organizations, of the scientific, technical, trade and national Press, and others were present by invitation. Some three or four hundred visitors saw exhibits illustrating the course of research during the past four years and the main aspects of the current research programme.

The interests of the Research Association cover a wide range of manufactured foods, with the exception of flour-milling, bread and bakery products, dairy products, and fruit and vegetable canning, all of which are the concern of separate research organizations. The research programme may be divided into three main categories: analytical problems in the routine control of quality; problems directly concerned with particular aspects of food manufacture; and more general investigations into fundamental principles with a bearing on the quality of the manufactured foods concerned. Some aspects of the work having wider scientific interest are outlined below.

The rheological properties of certain foods, including such diverse products as toffee, margarine, chocolate (in its fluid state), and starch, gelatine, agar and pectin jellies, have received considerable attention. A number of experimental pieces of apparatus were displayed, each designed to measure the force required to deform, or cause flow in, margarine and its allied product, compound cooking fat. One of these in particular, the 'extrusion plastometer', shows much promise in relating plasticity and 'spreadability' to readings taken on the instrument. Chocolate is processed during manufacture in a liquid state, and measurement of its rheological properties is of great importance in the chocolate industry. It has been shown to behave as a Bingham material, and measurement of its 'viscosity' raises considerable difficulty in factory practice. A number of commercial and experimental instruments which have shown promise of proving useful in factory control were exhibited. Investigations into the pasting of starch have been carried out by means of the corn industries viscometer. The measurement of the properties of jellies of various types is of interest in a number of foodstuffs. The Research Association has recently contributed largely to the design of the F.I.R.A. jelly tester, which incorporates several refinements, particularly in respect of design of the spade and reduction of friction, in comparison with the older B.A.R. tester. Recent work on the gelling properties of agar has shown how the instrument may be used for characterizing jellies and obtaining information beyond the measurement of pure 'jelly strength'.

The Research Association is studying the plastic composition and crystallization behaviour of cocoa butter and other fats through determinations of the specific heats and heat contents over a wide range of temperatures. From the measurements obtained, the percentage of liquid phase at a given temperatur may be calculated. An adiabatic calorimeter ha been constructed for the purpose of these studies, description of which will shortly be published elsewhere by Mr. E. H. Steiner. The procedure followe is intermediate between that described by A. E Bailey *et al.*[2] and that of J. Straub and R. N. M. A Malotaux as adapted by S. V. Vaeck[3]. The investigation is important in the study of the tempering o chocolate and the use of alternative fats in certai types of confectionery. The control of particle siz is of importance in many food products, such as icin sugar, cocoa powder, chocolate and starch. Amon the exhibits were a commercial vortex sieve for coco powder, a modified Andreasen sedimentation apparatus for chocolate and a Lea and Nurse air-permeability apparatus for the determination of specifi surface of several materials.

In the field of biochemistry, a study of the natur of the changes undergone by meat products, particularly colour changes in sausages, ham and othe cured meats, is being made from a fundamental poin of view; a note on one aspect of this work wa recently published by J. I. Anderton and D. J Locke[4]. The separation and study of vitamin A an related substances in liver oils is being undertaken by the use of a 'short-path' molecular still, chromatographic methods and the use of the quartz spectrophotometer. Fruits for jam-making and brine vegetables for the manufacture of pickles are both subject to undesirable tissue breakdown under certain conditions. The part played by pectolytic enzyme of the fruits and vegetables and those produced by moulds naturally present on fresh fruit and vegetable is being investigated in this respect. The Research Association maintains an extensive microbiologica laboratory for the study of both the desirable organisms that are necessary to such processes as the curin of bacon and the preparation of pickles, and th spoilage organisms which are a source of trouble i canned meat and fish products, and in pickles an sauces. Investigations of the thermal death-rat characteristics of mould spores which may caus spoilage in jam and of the bacteria and yeast responsible for spoilage in pickles are being carrie out.

On the technological level, the Research Association maintains pilot plant for studying the rate o heat penetration into canned goods under commercial conditions, and a laboratory-sized apparatu for carrying out pasteurization tests on jars o pickled onions has recently been designed an constructed. The packaging of manufactured food is an integral part of the interests of the Researc Association. While it does not concern itself wit the study of the properties of the various wrappin and packaging materials, it is concerned with th choice of material best suited to particular products In this connexion, a number of studies are undertaken, such as measurement of the vapour pressur of confectionery products, the protection of meta closures on glass packages from any corrosive effect due to the nature of the product packed in them or conversely, discoloration of the product in contac with the closure, and the effects of transparency an air-permeability of wrappers for margarine. The permeability of rubber sealing rings to gases and volatile substances is a cause of deterioration in meat and fish pastes, and the most desirable formulation for such rubber rings is being sought in collaboration with the manufacturers.

# RADIATION CHEMISTRY OF SOLUTIONS

THE fifth annual meeting of the Société de Chimie Physique was held in Paris during May 31–June 3, the subject of the meeting being the chemical effects of ionizing radiation. It was organized by Prof. G. Emschwiller and was attended by chemists and physicists from Europe, the United States and the U.S.S.R.

Radiation chemistry is complicated by the fact that the primary events are confined to the tracks of the ionizing particles. It was pointed out that in aqueous solutions the yield varies with radiation quality, the principal change occurring in the range 3·5–25 keV./μ mean linear energy transfer of the radiation. On the assumption that only those parts of the ionizing tracks where the linear energy transfer is greater than 25 keV./μ are effective, and taking δ-rays into account, a curve for the efficiency of different radiations has been calculated which is in good agreement with the experimental data for the molecular hydrogen yield (L. H. Gray). A tentative mathematical picture was given of the kinetics of radicals formed in a track (J. L. Magee). With increasing intensity, the tracks overlap and the kinetics of homogeneous solutions apply. This change was demonstrated using diphenylpicryl hydrazine in chloroform (A. Chapiro). There is a possibility that excited water molecules play a part in the indirect effects in dilute solutions (J. Weiss). However, the strict proportionality of fluorescence and sodium salicylate concentration in an aqueous solution exposed to α-radiation suggests the absence of indirect excitation of the solute (N. Miller).

The most useful system for the chemical measurement of dose is still a solution of 0·001 *M* ferrous ions in 0·1 *M* sulphuric acid. Several recent determinations for X-rays and β-rays have all favoured a value close to $G_{Fe^{+++}} = 15·5$ molecules per 100 eV. (N. Miller; A. J. Swallow; M. Cottin). An accurate determination has been carried out with 2 MeV. electrons and gives $G_{Fe^{+++}} = 15·45 \pm 0·11$ (R. H. Schuler and A. O. Allen, reported by N. Miller). The kinetics for the oxidation of $10^{-3}$ *M* ferrous ions in 0·1 *M* sulphuric acid are fairly well understood, but are totally inadequate to explain the high yield $G_{Fe^{+++}} = 63$ obtained in aerated solutions of $3 \times 10^{-3}$ *M* ferrous ions in 4 *M* sulphuric acid (Proskurnin, quoted by S. S. Medvedev). The sensitivity of yield to the presence of impurities was demonstrated with the $Fe^{++}$ system (N. Miller; C. Vermeil). For the measurement of exceptionally high doses, oxalic acid was recommended (I. Draganic). The measurement of dose by the ionization method depends upon the energy *W* required to form one ion-pair in air. Recent measurements with polonium α-rays give values close to *W* = 35·5 eV., in agreement with older data. New results for fast electrons obtained from a comparison of absolute counting-rates and ionization measurements of sodium-24, cobalt-60, gold-198, iodine-131 and phosphorus-32 lead to a value of *W* = 34 ± 1 eV. in air, differing slightly from *W* = 32·5 eV., the value widely used in radiological work (W. Emery, reported by L. H. Gray).

It was generally agreed that the initial products in the radiolysis of water are the free hydrogen and hydroxyl radicals and the molecular products hydrogen and hydrogen peroxide. The mechanism giving rise to the formation of the molecular products is not understood, but evidently it occurs in those parts of the tracks where the linear energy transfer is very high. The yields of molecular hydrogen are less affected than the yields of hydrogen peroxide by the presence of various solutes (M. Lefort and M. Cottin). New light was thrown on these processes by studies of radiation-induced polymerization and of the production of hydrogen peroxide in gas-free aqueous solutions of acrylonitrile. Both the monomer and polymer are inert to hydrogen peroxide, but readily combine with hydrogen and hydroxyl radicals. The yield of hydrogen peroxide varies with monomer concentration. It is at a maximum at $10^{-3}$ *M* and drops by a factor of 6 at the highest monomer concentration used, 0·5 *M*, when the monomer reacts with precursors of hydrogen peroxide even in the densest parts of the tracks (E. Collinson, F. S. Dainton and G. F. McNaughton). No similar demonstration of precursors of molecular hydrogen has yet been made. It might be formed directly from one water molecule, but the dependence of the yield on the linear energy transfer suggests a recombination process (M. Haïssinsky; G. Stein; M. Magat). Oxygen-18 has been used in a study of the production and decomposition of hydrogen peroxide by radiation (E. J. Hart, S. Gordon and D. A. Hutchinson).

Some of the aqueous solutions investigated are of biochemical interest. Irradiation of phosphoric acid esters of the homologous series of methyl to amyl alcohols shows that the larger molecules are more stable. The main products of decomposition are inorganic phosphate, acyl phosphate, aldehyde and hydrogen peroxide. All solutions show an after-effect if irradiated in the presence of oxygen. Analogous results with solutions of mononucleotides were reported (R. W. Wilkinson and T. F. Williams; G. Scholes; M. Daniels). Radiation effects on catalase in dilute aqueous solution show that quantitative results depend to a very large extent on the purity of the enzyme preparation. The enzyme is inactivated by hydroxyl radicals and not by hydrogen radicals as has been previously assumed (W. M. Dale and C. Russell; P. Bonet-Maury and F. Patti; H. C. Sutton, quoted by L. H. Gray). In contrast, reduction processes occur in solutions of methylene blue, coenzyme I and diphosphopyridine nucleotide (G. Stein; A. J. Swallow).

Irradiation of aqueous solutions of polyvinylpyrrolidine and other water-soluble polymers leads to degradation if the concentration is less than 0·3 per cent, and to cross-linking if more than 1 per cent (A. Charlesby and P. A. Alexander). The mechanism of cross-linking, however, is not yet understood (A. Henglein; Y. Landler). Irradiation of air-free solutions of methacrylic acid leads to polymerization which continues after the end of the exposure. The resulting polymer, dried and exposed to air for several hours, can still initiate polymerization in new unirradiated monomer solutions (M. Fox and P. A.

Alexander). Similarly, irradiated dry polymers can initiate polymerization in their own or different monomer solutions, even months after the exposure, thereby forming so-called graft polymers. These show a mixture of the physical properties of the parent substances (A. Chapiro; M. Magat). The reactions of diphenylpicryl hydrazine have been studied in great detail, showing that substitution occurs in the *p*-position of the phenyl groups (A. Henglein; W. Wild). Irradiated solutions of diphenylpicryl hydrazine show an after-effect lasting for several weeks. Some discrepancies between the experiments with this substance in Britain, France and Germany seem to have been due to differences in analytical procedures and conditions of irradiation (W. Wild; A. Chapiro; A. Henglein). The loss of colour of diphenylpicryl hydrazine, irradiated in mixtures of organic solvents, does not follow a simple additive law, indicating energy transfer from one solvent molecule to the other (A. Chapiro; S. S. Medvedev). Similar evidence of a non-additive effect has been observed in the luminescence of *p*-terphenyl induced by γ-irradiation in mixtures of benzene and *cyclo*hexane (M. Burton, P. J. Berry and S. Lipsky). The use of radiation as an energy source in preparatory organic chemistry was demonstrated in halogenation reactions of aromatic compounds and in the synthesis of methylene blue and other organic substances (D. E. Harmer, J. J. Martin and L. Anderson; J. Loiseleur).

Many of those who attended both this meeting and the Faraday Society Discussion on radiation chemistry in Leeds in 1952 felt that in Paris there was less controversy about possible radical intermediates, most of the new results falling into line with accepted schemes of radical formation and reaction. Even the concept of the 'molecular yield' which has had considerable prominence showed signs of giving way to interpretation in terms of these schemes.

P. Howard-Flanders

# POLAROGRAPHIC INSTRUMENTATION

## FIRST SYMPOSIUM OF THE POLAROGRAPHIC SOCIETY

By invitation of Prof. F. S. Dainton, the first symposium of the Polarographic Society was held in the Chemistry Department of the University of Leeds on May 25. In its emphasis on the design of polarographic instruments, this meeting is believed to have been the first of its kind to be held in Great Britain. After Prof. Dainton had extended a welcome to the Society, the chairman mentioned the steps leading to its recent formation and briefly outlined its objects.

In most cases, those reading papers explained the essential principles of the circuits employed in their instruments. C. Wontner described a simple manual polarograph and demonstrated its use in obtaining current/voltage curves. These can be plotted with surprising speed because of the semi-automatic location of the voltage scale in a series of 10-mV. steps. By virtue of a magic-eye null-point detector, the manual polarograph described by G. O. Jolliffe measures the true maximum current and so eliminates assumptions about the detector's equation of motion. This instrument is also of interest to the polaro graphic research worker in that it contains facilitie for measuring both current and voltage potentio metrically.

A pen-recording polarograph, which possesses photovoltaic amplifier of very short time-constan was described by E. A. Wood and Mrs. B. Lamb The design of an associated condenser/resistanc differentiating unit for use in derivative polarograph was also explained. G. L. Young dealt with a pen recording instrument involving a different typ of amplifier and paid special attention to th theoretical aspects of an attachment which enable the instrument to record true derivative peaks b the a.c. polarographic method of Breyer and Gutmann

After dealing with the rather differently shape waves encountered in cathode-ray polarography G. F. Reynolds gave an outline of the theory b explaining the equations of Randles and Sevcik Apart from being more sensitive than conventiona instruments, the Chemical Inspectorate, Randles type, single-sweep polarograph can also be operate with greater speed and simplicity. In its resolutio of closely spaced steps and compensation for preceding step, the instrument's normal performanc is between that of the 'conventional' and th 'derivative' polarograph. However, the incorporatio of a derivative circuit enables it where necessary t achieve the resolution of the derivative polarograp together with a much greater sensitivity. Mr Reynolds expressed the view that, in general, th sensitivity and applicability of the cathode-ra polarograph are equal to that of the square-wav polarograph at its present stage of development The design principles of a single-sweep cathode-ra polarograph were then given by H. W. Rowe-Leete, who also dealt with the electronics in terms of block diagrams.

By way of a contrast to these purely instrumenta contributions, Mrs. N. Luthy read a paper on the application of the polarograph to pyrimidine chemistry, with particular reference to the detection o the —S—S— bond.

# LIBRARY RESOURCES IN THE MANCHESTER AREA

A CONFERENCE on library resources for industry and commerce in the Manchester area was held in Manchester on March 10 by the Northern Branch of Aslib. The speakers were Mr. D. I. Colley, Manchester City librarian; Mr. V. D. Freedland, information officer of the British Hat and Allied Feltmakers Research Association; Mr. L. L. Ardern, librarian of the Manchester College of Technology; and Mr. R. Brightman, bibliographer of the Dyestuff Division, Imperial Chemical Industries, Ltd.

In his survey of the services provided by the City Library, Mr. Colley emphasized their diversity. The main point is that these services have to meet the varied need of the rate-payers who pay for them. The commercial and technical libraries, while important and highly developed, are but two sections. This dependence on local finance necessarily limits developments. This is unfortunate, he said, because a census taken during 1954 showed that some 40 per cent of the users of the reference libraries were not rate-payers. Moreover, an analysis of this 40 per cent showed that Manchester is not only providing a gional service but also a national, even international, ne. In these circumstances, Mr. Colley maintained, it oes not seem unreasonable to seek national support.

The major part of Mr. Freedland's paper consisted f an analysis of the holdings of some forty special braries situated within a radius of twenty miles of he centre of Manchester. It was based on some of he replies to a questionnaire issued by Mr. A. L. myth, of the Reference and Special Libraries North-west Group) of the Library Association. For onvenience of presentation, Mr. Freedland grouped hem under broad headings such as chemical production, textiles, engineering and the production and istribution of fuel and power. There are, he egretted, certain libraries which he was unable to nclude in his survey as they appeared to pursue a olicy of non-co-operation in any of the various hemes for mutual assistance and collaboration.

Mr. Ardern spoke on the Manchester College of echnology Library and its assistance to industry. t began in 1824 as the library of the Manchester Mechanics Institute, and it still has many hundreds f the original volumes, of particular interest being he collection which had belonged to J. P. Joule. A ew weeks ago the draft of a twelve-page letter which oule had written in 1853 to William Hopkins, the ambridge scientist, was found in one of these books. ne of Joule's note-books, which was not recorded when r. Lowery described them in 1931, is in the library.

The library carries a stock of forty thousand olumes, five hundred current periodicals and the heses awarded for the degree of master of technical cience in the University of Manchester. A large ollection of standards is maintained, including those f the American Society for Testing Materials, the ociety of Automotive Engineers and the Society of lastics Industry. Many loans are made to industry, nd the library will continue to welcome inquiries.

Mr. Brightman addressed the meeting as a library ser. The public library, he thought, will be most seful to the firm which already possesses its own nformation service, and its chief value is in meeting marginal needs. Such a service can only be given if he public library does not fall below a minimum ze. By co-operation, industry expands the public brary service, and this implies development upon a egional basis. But it is not possible wisely to plan egional developments without regard to the national brary system as a whole. The Royal Society's cientific Information Conference in 1948 urged the overnment to give increased support to central cientific libraries and stressed the need for cooperation in local areas. The Advisory Council on cientific Policy appointed its own Scientific and echnical Information Committee, which reported on he needs of a national library of science and invenons, and plans for a new science centre were pproved in principle by the Government in 1950. n December 1952, however, the Minister of Works nnounced the postponement of the whole scheme—ven its planning. Apart from a protest in *Nature* nd by Dr. Colgate in his Armstrong Memorial ecture, this decision was unchallenged.

Last year, however, the Advisory Council expressed he hope that steps would be taken without undue elay to implement the scheme, and endorsed a report y its standing committee that there is a need for a ew science lending-library outside London, preferbly in a place easily accessible to the industrial reas of the North and Midlands, and that this library hould be the centre of a regional loan system based on selected municipal libraries. It is understood that the Government is now considering this.

The discussion which followed the four papers concentrated on the possibilities of achieving closer co-operation between local libraries and on the ways of bringing pressure on the Government to proceed with the science centre. The Northern Branch Committee was urged to take the matter up.

# RADIO COMMUNICATION BY WAVE SCATTERING

It has been known for some twenty years or more that in addition to the normal process of reflexion at the various regions of the ionosphere, by means of which most long-distance communication is conducted, radio waves could be scattered in various directions from the point of incidence on the ionosphere. Such scattered radiation is usually very weak and not easily detected by normal methods of reception. In 1952, however, a paper was published by a group of workers in the United States describing experiments conducted on a frequency of 49·8 Mc./s., during which easily measurable signals were obtained over an experimental path 1,245 km. long. While the strength of the observed signals passed through a maximum at about midday and a minimum at about 20 hr., there was no failure over a period of several months resulting from conditions in the scattering medium.

The success of such experimental transmissions relied on the concentration of the emitted radiation into a narrow beam directed at the correct angle to secure forward scattering from irregularities in the lower regions of the ionosphere. A narrow-angle receiving aerial was also used, directed so as to ensure maximum reception from the same portion of the ionosphere as was 'illuminated' by the radiation from the transmitter. Much interest was aroused by these and later experiments, which clearly offered the possibilities of opening up new channels in the very high frequency band between 30 and 100 Mc./s. for a limited range of distances between about 800 and 2,000 km.

While it has been known that further investigations were in progress in the United States, Canada and the United Kingdom, very little of the scientific or practical results obtained has so far been published. It is therefore of considerable interest to note the recent announcement by the Massachusetts Institute of Technology of the development of new methods of sending radio waves over useful distances for communications as a result of research conducted for the United States Air Force. Dr. W. H. Radford, head of the M.I.T. Lincoln Laboratory's communications division, is reported in *The Times* of July 18 to have said that the first application of these new systems would be in connexion with the defence of the United States and Canada. The use of very high frequency ionospheric scattering as referred to above is of particular advantage in high-latitude and arctic regions, where conditions in the ionosphere for normal high-frequency (30 Mc./s. and below) propagation are subject to storms, resulting in great variability and interruption of radio communications. It is understood that some circuits operating on these principles and using teletype transmission are already in operation.

In an analogous manner, radio waves in the ultra high frequency band above 300 Mc./s. can be used for communication over somewhat shorter, but still useful, distances of the order of 500 km., by forward scattering of the waves from irregularities in the troposphere at a height of a few kilometres. A similar use of high effective power, directive aerials and sensitive receivers is required but, on account of the higher frequency employed, a greater resulting band-width can be made available for normal radio telephony operation. Until more information is disclosed as to the scientific and practical results of the investigations in progress in various parts of the world, the full possibilities of communication systems based on the forward scattering of radio waves in the ionosphere and troposphere cannot easily be visualized. Further publication of the results of recent investigations in these fields will be awaited with interest by all those concerned with the future of radio communication.

# VEGETATION OF THE ASSAM VALLEY

IN Vol. 9, No. 1, of *Indian Forest Records* (pp. iv + 87 + 4 plates. Delhi: Manager of Publications, 1954), J. B. Rowntree, formerly conservator of forests, Assam, writes on an "Introduction to the Vegetation of the Assam Valley". In 1938 Dr. N. L. Bor, on deputation among the head-hunters of the Aka Hills, Assam, wrote a detailed account of the vegetation of that area. A first attempt to classify the vegetation of India was made by Mr. (now Prof.) H. G. Champion in 1935 in "A Preliminary Survey of Forest Types in India and Burma". The area covered did not permit of great detail being given. The present work is an attempt to do the same for the whole of the Brahmaputra valley.

The object aimed at was to collect all the existing data on the subject, with additions from personal knowledge of all the communities described, especially
with respect to the *Dipterocarpus–Mesua–Michei*
association and the *Shorea–Schima–Lagerstroem*
pro-climax. To the north of the Brahmaputra t
river runs practically north and south, and from t
foot of the hills the land drops on a gentler slop
The hill areas are covered with forests; but, owi
to the prevailing habit of shifting cultivati
(*jhuming*), the climatic climax formation is but rare
met with, and the forest is mostly of secondary growt
In most of India this practice was stopped by t
British Government; but this action did not exte
to the remote Assam of those days. As in the ca
of Africa, so here; Mr. Rowntree states: "In old
times when the population was kept in check l
wars and disease no great harm was done, b
nowadays with the population increasing (in plac
at alarming rates) this is no longer the case". T
*jhuming* rotation is becoming shorter and short
and in places is down to three years. As a resu
the ground-cover appears to be retrogressing fro
tree growth to bamboos and finally to grass, the s
is decreasing in fertility and erosion increasing fro
year to year, with floods silting up valuable pla
land.

The main reserved forests lie along the foothi
with detached blocks on higher land in the plair
The tropical evergreen formation is in Upper Assa
and the *Shorea robusta* association in Lower Assa
Among biotic factors man, as has been shown, pla
a predominant part, followed by animals, gia
climbers and epiphytes, insects, soil algæ, bacter
and earthworms.

Having disposed of the factors of climate, geolo
and soils and so forth, Mr. Rowntree, in a seri
of chapters, deals with the classification of th
communities, the tropical *Cinnamomum–Amoor*
*Michelia* formation and its associates, the deciduo
*Shorea* formation and other groups, grasslands a
savannahs, and so forth. Appendixes give map
and there are a few illustrations. To the fore
officers and those interested in the flora of this littl
known part of the world, the work should pro
invaluable.

E. P. STEBBING

# RELATIONSHIP BETWEEN CERTAIN COMPONENTS OF THE CYTOCHROME SYSTEM

By PROF. D. KEILIN, F.R.S., and DR. E. F. HARTREE
Molteno Institute, University of Cambridge

OF the components of a typical cytochrome system only cytochrome *c* has so far been isolated in a soluble and completely pure state. By a very simple procedure[1], cytochrome *c* containing 0·34 per cent iron can be obtained from heart muscle on a large scale, while further purification[2-4] yields fractions with iron contents of 0·43–0·45 per cent. Although the properties of this isolated or exogenous cytochrome *c* are in general independent of the method of extraction and of the degree of purification, its catalytic activity, as determined with a heart-muscle preparation of cytochrome oxidase[5], is much lower than that of the endogenous pigment present in this preparation[4,6-9]. Furthermore, only exogenous cytochrome *c* combines with cyanide within the physiological range of *p*H[10-14].

These differences between the two forms of cytochrome *c* appear to favour the view that it undergoes a marked change on extraction. However, two considerations militate against this view. (1) Cyt
chrome *c* which has been obtained by a very mi
method of extraction of washed heart-muscle min
with phosphate buffer has the same properties[15]
the pigment obtained by the usual, more drast
method[1]. (2) The catalytic activity of the cyt
chrome system in a particulate heart-muscle prepar
tion depends upon appropriate spatial distributi
of all components of the system; in other wor
upon an arrangement within the particles whi
assures their mutual accessibility. In this respe
endogenous cytochrome *c* is more favourably plac
for electron transfer reactions than is the exogeno
pigment. That there is no essential difference betwe
the exogenous and endogenous forms was demo
strated by a transformation of the former into t
latter[15]. This was achieved by adding extract
cytochrome *c* to a washed heart-muscle min
previously made deficient in cytochrome *c*, and th

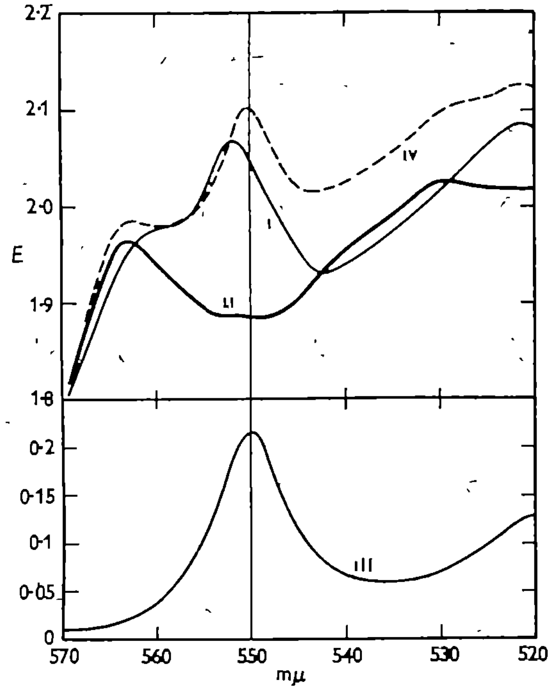

Fig. 1. Absorption spectra of heart-muscle preparation reduced with succinate or with succinate + antimycin *A*. Effect of adding cytochrome *c* to the latter. (i) Preparation + succinate. (ii) As (i) + 20 μgm./c.c. antimycin *A*. (The solution was aerated periodically to maintain all cytochromes except *b* in the oxidized state.) (iii) 16 μ*M* cytochrome *c* + sodium dithionite. (iv) Optical mixture of solutions (ii) and (iii). *E* = extinction (optical density)

obtaining from this mince our standard type of muscle preparation[8]. The now re-incorporated cytochrome *c* was found to be indistinguishable from the normal endogenous cytochrome *c* of such preparations[10].

## Variations in the Position of the c-Band of the Cytochrome Spectrum and Evidence for an Additional Cytochrome Component

While the α-band of reduced cytochrome *c* in solution lies at 550 mμ, the position of this band in preparations of heart muscle and other tissues, as well as in certain bacteria, has been recorded spectrophotometrically as 551–552 mμ[1-5].

The study by conventional spectrophotometric methods of heart-muscle preparations suspended in buffers is scarcely practical since the loss of light by scattering is much greater than the decrease arising from absorption. It has been customary to add bile salts to such preparations, which leads to a considerable degree of clarification and, in addition, to plot difference spectra (for example, oxidized against reduced forms) in order to reduce still further the effects of scattering. Since bile salts have inhibitory actions on some catalytic components of the heart-muscle preparation, we have used high concentrations of sucrose in place of bile salts.

In order to determine as precisely as possible the relative α-band positions for soluble cytochrome *c* (horse heart) and for endogenous cytochrome *c* in the heart-muscle preparation, we have used a Hilger 'Uvispec' spectrophotometer fitted with a glass prism. The resulting high dispersion allows wavelength settings to be made accurately to 0·1 mμ in the greater part of the visible region. By reading extinctions at 1 mμ intervals and constructing a smooth curve the band maxima could be estimated with an error of ≯ 0·3 mμ. A comparison between a calibrated didymium glass filter and a solution of reduced cytochrome *c* in phosphate buffer *p*H 7·3 at 20° gave the position of the α-band of soluble cytochrome *c* as 550·0 mμ. Heart-muscle preparations were suspended, after isoelectric precipitation[6], not in the customary phosphate buffer but in a sucrose phosphate solution (200 gm. sucrose in 100 c.c. 0·25 *M* disodium phosphate) and examined in 0·5 cm. cuvettes. The extinction of these suspensions was 1·5–2·0 at 550 mμ. Repeatable readings of these high extinctions were obtained by using the makers' high-intensity filament lamp, taking extinction (*E*) readings against a blank cuvette containing paraffin-soaked filter paper (*E* ~ 1) and correcting for the extinction of the latter. Under these conditions it was possible to work with a slit-width of 0·2 mm., which is equivalent to a 5 mμ band-width at 550 mμ.

The results of our experiments can be summarized as follows.

(1) The position of the α-band of cytochrome *c* in heart-muscle preparations reduced with either sodium succinate or sodium dithionite is near 552 mμ (Fig. 1, (i)), the mean figure from numerous experiments being 551·7 mμ. In no case was the band position modified by treatment with cyanide (1 m*M*) or carbon monoxide.

(2) The equivalent band in a cytochrome *c*-deficient heart-muscle preparation, which is measured as a shoulder on the short-wave side of the band *b*, lies between 553 and 554 mμ (Fig. 2, (ii)).

(3) When a solution of cytochrome *c* (α, 550 mμ) is added to cytochrome *c*-deficient heart-muscle preparation in amounts approximately compensating the deficiency and the mixture is reduced with succinate or sodium dithionite, the α-band of the added cytochrome *c* is seen to be at 552 mμ (Fig. 2, (iv)). This band-shift could conceivably be due to four causes: (i) A reaction between exogenous cytochrome *c* and some constituents of the heart-muscle preparation which affects the absorption

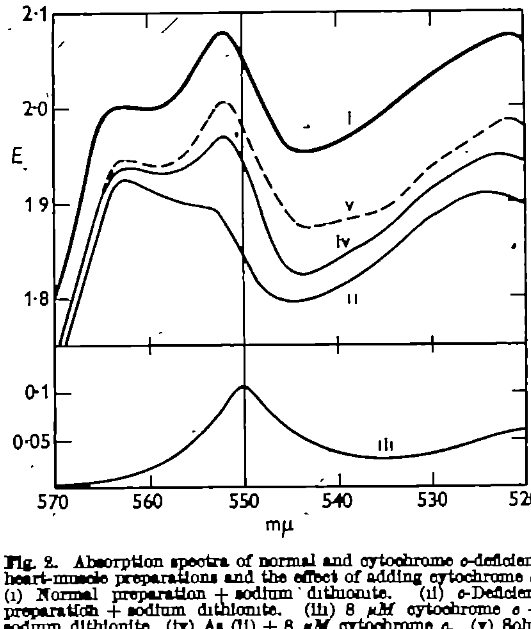

Fig. 2. Absorption spectra of normal and cytochrome *c*-deficient heart-muscle preparations and the effect of adding cytochrome *c*. (i) Normal preparation + sodium dithionite. (ii) *c*-Deficient preparation + sodium dithionite. (iii) 8 μ*M* cytochrome *c* + sodium dithionite. (iv) As (ii) + 8 μ*M* cytochrome *c*. (v) Solutions (ii) and (iii) in adjacent cuvettes (optical mixing). *E* = extinction (optical density)

spectrum of cytochrome *c*. (ii) An effect of the overlap of the α-bands of cytochrome *c* and cytochrome *b* (563 mμ). (iii) A result of light-scattering by the heart-muscle preparation. (iv) An effect of some other component with an absorption band close to that of cytochrome *c*. Each of these possible causes will be examined separately.

(i) The possibility of a reaction between exogenous cytochrome *c* and a constituent of the heart-muscle preparation was easily dismissed, since the shift of the α-band towards 552 mμ takes place not only when cytochrome *c* is added to cytochrome *c*-deficient heart-muscle preparation but also when they are mixed optically, that is, by placing a solution of cytochrome *c* and the deficient heart-muscle preparation in separate adjacent cuvettes in the light-beam (Fig. 2, (v)).

(ii) An effect of the absorption spectrum of cytochrome *b* can be readily eliminated. Thus, if a solution of cytochrome *c* is added to cytochrome *c*-deficient heart-muscle preparation and the mixture reduced with either ascorbic acid or cysteine, which do not reduce cytochrome *b*, the α-band of cytochrome *c* appears to be nearer to 552 mμ than to 550 mμ.

(iii) An explanation in terms of light-scattering is improbable since the addition of light-scattering material, such as milk, to a solution of reduced cytochrome *c* does not change the position of its absorption bands.

(iv) The shift of the α-band of reduced cytochrome *c* from 550 to 552 mμ must therefore be due to the presence in heart-muscle preparations of an extra pigment, which we shall temporarily refer to as *P*, with an absorption band lying near 550 mμ. The following experiments provide further evidence for this view and also reveal the nature and function of *P*.

(4) Since cytochrome *c* is the only cytochrome component which is known to be thermostable, it was of interest to determine the absorption maximum in the heart-muscle preparation after heat treatment. After heating heart-muscle preparation for twenty minutes at 70° and then reducing it with sodium dithionite or ascorbic acid, the only bands visible are those of cytochrome *c*, the α-band of which is now at 550 mμ.

(5) An optical mixture of reduced cytochrome *c* and untreated (that is, oxidized) heart-muscle preparation shows an α-band at 550 mμ. This indicates that *P* undergoes oxidation and reduction and that only its reduced form affects the spectrum of reduced cytochrome *c*.

(6) In an optical mixture of reduced cytochrome *c* in solution and heart-muscle preparation reduced in presence of antimycin *A* with either succinate or DPNH (reduced coenzyme I), the α-bands of cytochromes *c* and *b* are at 550 and 563 mμ respectively (Fig. 1). If it is assumed that *P* is a cytochrome type of pigment showing only diffuse absorption in the visible region when it is in the oxidized form, this experiment indicates that *P* remains oxidized while component *b* is reduced. In other words, the reduction of *P*, like that of cytochromes *a* and *c*, is inhibited by antimycin *A*.

(7) The positions of the *c* band in a heart-muscle preparation containing 1 m*M* cyanide and reduced with either 10 m*M* potassium ferrocyanide or a 10 m*M* mixture ferrocyanide/ferricyanide = 70 were at 551 and 550 mμ, respectively. Since cytochrome *b* remained completely oxidized in both cases, these results indicate that the oxidation-reduction potential of *P* lies between those of cytochromes *b* and *c*.

(8) The main properties of *P* can thus be enumerated as follows. (i) It is thermolabile. (ii) It can undergo oxidoreduction. (iii) It can be reduced in the heart-muscle preparation with those reagents which also reduce the cytochrome *c* of the preparation, for example, ascorbic acid, cysteine, sodium succinate and DPNH. (iv) Its reduction by succinate or DPNH is inhibited by antimycin *A*. (v) Its oxidation is catalysed by the cytochrome oxidase system; the compound is therefore not autoxidizable. (vi) It does not appear to react either with cyanide or with carbon monoxide. (vii) Its oxidation-reduction potential lies between those of cytochromes *b* and *c*. (viii) In the oxidized state it has a diffuse absorption spectrum, whereas in the reduced state it must show a strong absorption band lying between the α-bands of cytochromes *b* and *c* and close enough to the latter to shift its apparent maximum from 550 to ~ 552 mμ (Fig. 2). These points suggest that *P* is a thermolabile, non-autoxidizable, antimycin-sensitive cytochrome component with absorption bands in the reduced state lying near those of cytochrome *c*. Like other components of cytochrome, it forms an integral part of the electron transfer chain between activated substrate molecules and molecular oxygen.

## Identity of the Pigment responsible for the Shift in the *c*-Band with Cytochrome *e*

A component of cytochrome which exhibits the properties enumerated above is cytochrome *e*, which we discovered during spectroscopic examination of heart-muscle preparations, and of suspensions of different cells, at the temperature of liquid air[11,12].

The success of such experiments at liquid-air temperature (– 190°) depends upon the presence of glycerol in the suspending medium and upon the use of a low-dispersion (direct-vision) spectroscope. When the glycerol concentration exceeds 55 per cent (v/v) the suspension freezes to a translucent glass, while the absorption bands of pigments in the suspension become very sharp and move towards the blue end of the spectrum. Furthermore, groups of bands that cannot be resolved at room temperature become distinctly separate and may themselves show additional fine structure. When the glycerol concentration is 48–50 per cent, further band modifications can be observed. On rapid cooling to – 190° such suspensions freeze to a glass and show the same band-sharpening as was observed with higher proportions of glycerol. When these frozen samples are allowed to warm up slowly they devitrify to a microcrystalline mass which, after re-cooling in liquid air, shows the bands not only sharpened and shifted to lower wave-lengths but also very markedly intensified. Under these conditions a much lower concentration of material is required, but the devitrified mass, being opaque, can be studied only by means of a very low dispersion spectroscope (for example, microspectroscope or hand spectroscope) together with a powerful source of light.

Both methods of cooling have been applied to the study of cytochromes. Spectroscopic examination at low temperatures of the heart-muscle preparation reduced with succinate or sodium dithionite shows the recognized cytochrome components with very sharp bands displaced 2–3 mμ towards the blue. Thus the α-bands of cytochromes *a*, *b* and *c* now lie at about 600, 560 and 548 mμ, respectively. More-

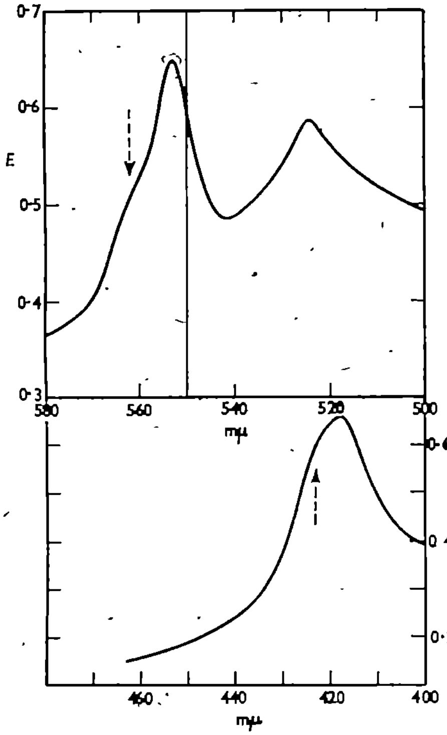

Fig. 3. Absorption spectrum of cytochrome $c_1$ (= cytochrome *e*) (reduced by sodium dithionite in presence of 0·4 per cent sodium cholate at pH 7·3). Upper curve: 2 cm. cuvette. Lower curve: 0·5 cm. cuvette. Shoulders to α- and γ-bands (arrows) represent residual cytochrome *b*

ver, the space between the *b*- and *c*-bands becomes learer and a very sharp band appears at about 551–552 mμ. As the temperature rises, this band isappears rapidly—well before bands *b* and *c* begin o lose much of their acquired sharpness. This and ther similar observations lead us to believe that – 190° is near the upper limit of a range of temperatures within which more dramatic changes of lready sharpened bands would be observed. It can eadily be shown that the sharp band at 551–552 mμ, bserved at low temperatures, belongs to the component which we called cytochrome *e* and is not an dditional peak in the sharpened absorption spectra f cytochromes *b* or *c*. Thus this band fails to appear n cooling a heart-muscle preparation in which only ne of the cytochromes, either *b* or *c*, is present in he reduced state. The '*c* only' spectrum was obtained y heat treatment and reduction with sodium ithionite, while the '*b* only' spectrum was obtained y aerating heart-muscle preparation in presence of uccinate and antimycin *A*.

As judged by the wave-length of the *c*-band in a ariety of cells and tissue preparations, the distribution of cytochrome *e* is very wide. Since cooling o liquid-air temperature shifts the positions of bsorption bands 2–3 mμ towards the short-wave nd of the spectrum, the position of the α-band of ytochrome *e* at room temperature should be at 553–554 mμ. By applying to a horse-heart muscle xtract a modification of the method used by mith and Stotz[13] for extracting cytochrome oxidase rom pig heart we have been able to obtain a clear olution of cytochrome *e* which shows the absorption axima α-553, β-524, γ-418 mμ. As will be shown ater, this compound is identical with the previously escribed cytochrome $c_1$. This solution is free from cytochrome *c* and contains only traces of cytochromes *a* and *b* (Fig. 3). Its absorption spectrum is unchanged by treatment with carbon monoxide.

## Limits to Resolvability of Groups of Absorption Bands

The question that now arises is whether the α-band of cytochrome *e*, lying in the region of 554 mμ between those of cytochrome *b* (563 mμ) and cytochrome *c* (550 mμ), should be detectable spectrophotometrically in a heart-muscle preparation.

Three possibilities can be considered. Thus the *e*-band might form a distinct maximum in the absorption curve, it might form a shoulder to the *b*- or *c*-bands, or it might fuse with the closely situated *c*-band to give a virtually symmetrical band with a peak at an intermediate wave-length. We shall assume that the α-bands of cytochromes *b* and *e* are of the same shape as that of cytochrome *c* and then consider to what extent the three bands would be resolvable if their relative heights were varied and if the position of the *e* maximum were varied over the range 553–555 mμ.

Fig. 4 shows four such absorption curves with peaks at 563 (*B*), 554 (*E′*), 553 (*E*) and 550 mμ (*C*), corresponding to the α-bands of cytochrome *b*, cytochrome *e* (two alternative positions) and cytochrome *c*. In Fig. 5 are shown curves obtained by summation of the curves in Fig. 4 as follows:

$l = B + E + C \qquad l' = B + E' + C$
$m = B + 0{\cdot}5\,E + C \qquad m' = B + 0{\cdot}5\,E' + C$
$n = 1{\cdot}5\,B + 0{\cdot}5\,E + C \qquad n' = 1{\cdot}5\,B + 0{\cdot}5\,E' + C$

The upper set of curves in Fig. 5 shows that a symmetrical '*c*-band' can be expected when the heights of the individual bands *C* and *E′* are equal (*l′*), but that a shoulder appears at about 554 mμ when the concentration of *E′* is reduced (*m′*, *n′*). Since the original spectroscopic observations on cytochrome *e* indicated that its concentration in heart-muscle preparation is less than that of cytochrome *c*[11], the absence of any shoulder to the *c*-band in spectrophotometric curves of heart-muscle preparations would suggest that the α-band of cytochrome *e* is less than 4 mμ from the α-band of cytochrome *c*. If a similar summation of α-bands is made on the basis of an *E′* maximum at 555 mμ, the *c*-bands of all three curves are very asymmetrical. Curves *l*, *m*, *n*, which are calculated from an *E*-band at 553 mμ,

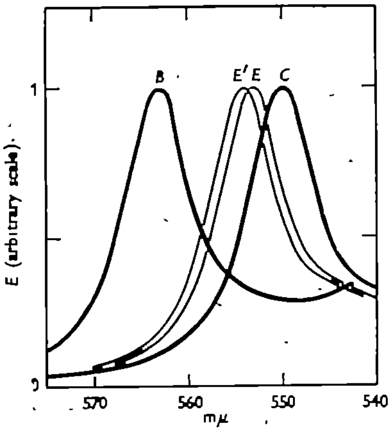

Fig. 4. α-Band of cytochrome *c* (*C*) together with the same band reproduced with maxima at 563, 554 and 553 mμ (*B*, *E′*, *E*)

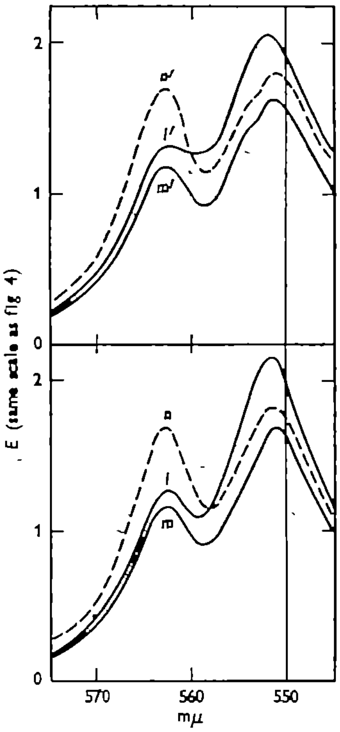

Fig. 5. Curves obtained by summation of curves in Fig. 4 as described in the text. Band peaks: *l*, 551·7; *m*, 551·0; *n*, 551·5 mμ

differ from *l'*, *m'*, *n'* mainly in the absence of shoulders to the *c*-bands. On the basis of experiments to be described elsewhere, the $B:E:C$ ratio represented in summation by curve *n* is considered to approximate to that in a normal heart-muscle preparation, and the wave-length of maximum extinction in this curve (551·5 mμ) agrees within experimental error with the wave-length found for heart-muscle preparation (551·7 mμ). Furthermore, the difference between the *c*-band maxima of *n* and *m* indicates that the *b*-band can influence the position of a maximum due to the fused bands of cytochromes *c* and *e*. This shift can be demonstrated experimentally with the cytochrome *c* - deficient heart-muscle preparation (Fig. 6). The difference spectrum *x* (heart-muscle preparation reduced with succinate *minus* oxidized preparation) shows the α-peak of cytochrome *b* at 562·5 and that of cytochrome *e* at 553·7 mμ. When succinate is replaced by ascorbate (*y*), cytochrome *b* is not reduced and the *e*-maximum now appears at 552·8 mμ, which is essentially identical with the 553 mμ maximum found for isolated cytochrome *e* (Fig. 3). (As stated above, the positions of band maxima could be determined to within 0·3 mμ.) The effect of liquid-air temperature is thus to shift the position of the *e*-band in the heart-muscle preparation from 554 to 552 mμ. An examination of isolated soluble cytochrome *e* (= cytochrome $c_1$) revealed a similar shift from 553 to 551 mμ. The outstanding difference between the summation curves of Fig. 5 and those obtained from the heart-muscle preparation lies in the more pronounced minimum between the *b*- and *c*-bands of the former. While the virtual absence of a minimum in heart-muscle preparation curves (see Fig. 2, (i)) may be the result of absorption by a so far unidentified pigment or of a minor contribution from cytochrome *a*, we hope to show, in a later publication, that the discrepancy arises more probably from the light scattering properties of the preparation.

## Cytochrome $b_5$ and Cytochrome *e*

Already at an early stage of the work on cytochrome it was recorded that the fat body of blowfl larvæ shows an absorption spectrum composed o three bands at 603, 558 and 524 mμ[14]. Thus th components *b* and *c* are replaced in this instance b a single component showing a protohæmochromoge type of absorption spectrum (α-558, β-524 mμ). A component with a similar absorption spectrum wa later found by Sanborn and Williams[15] to be generall distributed in tissues of the *Cecropia* silkworm an was described by them as cytochrome *x*. Anothe very similar pigment with bands at 557, 527 an 424 mμ was found by Strittmatter and Ball[16,17] to b the main cytochrome component of rat-liver microsome fractions. This pigment was probably responsible for masking the α-bands of cytochromes *b* and in our earlier cell-free preparations from liver an kidney[18], and, in fact, by modifying our procedur in such a way that the microsome fraction would b discarded, Slater[8] was able to obtain kidney preparations which showed clear *b*- and *c*-bands. Mor recently, the pigment from *Cecropia* silkworm midgut under the name of cytochrome $b_5$, was re-investigate by Pappenheimer and Williams[17]. According to thes authors, "cytochrome $b_5$ probably accounts for muc of the cyanide-, carbon monoxide-, and antimycin- resistant DPNH oxidation, not only in the insect but also in plant and animal tissues as well". Chanc and Pappenheimer[18], who believed they could identif cytochrome $b_5$ with cytochrome *e*, wrote, "The clea absorption bands of cytochrome $b_5$ as measured b the recording spectrophotometer are in considerabl contrast to the wide, indistinct band that is seen i the microspectroscope, on the basis of which Keili and Hartree identified the pigment as a specia cytochrome *e*. Thus the peculiar appearance of th

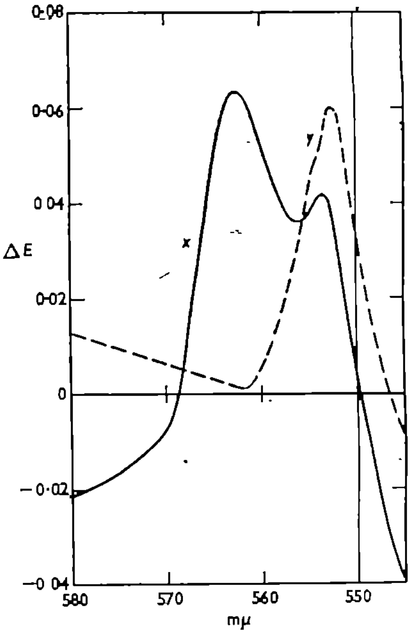

Fig. 6. Difference spectra of cytochrome *c* - deficient heart-muscle preparation. *x*: Preparation + succinate *minus* untreated preparation. *y*: Preparation + ascorbate *minus* untreated preparation

band of this pigment in the microspectroscope ould no longer be a bar to its identification with e cytochrome $b$ family in view of the clear cut band bserved in our recordings". This very misleading atement raises a number of points which call for iticism.

(1) Cytochrome $e$ was observed by us in cells, ssues and cell-free preparations only when they ere cooled to liquid-air temperature, and under ese conditions we described the α-band, as seen ith a microspectroscope, not as wide and indistinct ut as exceptionally sharp[21]. In fact, as we have own, it is the band sharpening at low temperatures hich makes possible the resolution of bands as close gether as those of cytochromes $c$ and $e$.

(2) Contrary to the view developed in the above otation, it is generally recognized that a band hich appears wide and indistinct when examined ith a low-dispersion spectroscope will appear still ss distinct when recorded with a spectrophotometer hich, of necessity, must have a much higher dis- ersion. As an example, we may consider the oulder at 563 mμ in Fig. 3, which appears as a istinct band when examined with a microspectro- ope. The same applies to the α-band of ferricyto- rome $c$ or other parahæmatin compounds which n be seen as a separate band with a microspectro- ope but which appears as a scarcely perceptible regularity on the long-wave side of the β-band in spectrophotometric curve.

(3) The view as to the identity of cytochromes $b_5$ nd $e$ put forward by Chance and Pappenheimer[22] is ot supported by a systematic comparison of these wo components. Thus it was previously shown that tochrome $b_5$ is autoxidizable, that its reduction by e succinic dehydrogenase system is very slow, that s reduction by DPNH is rapid but not affected by timycin $A$ and that its α-band lies at 558 mμ. We ave now shown that cytochrome $e$ is not autoxidiz- ble, that its reduction by the above systems is pid and inhibited by antimycin $A$, and that its band lies at 553 mμ. Moreover, where structural ements of cytoplasm could be separated, cyto- rome $e$, like cytochromes $a$, $b$ and $c$, was found to localized within mitochondria, whereas cyto- rome $b_5$ was found associated with the microsomes. hile cytochrome $b_5$ shows a marked resemblance to her components of the $b$-group, cytochrome $e$, as ill be seen, is more appropriately classified with tochrome $c$.

## Identity of Cytochrome e with Cytochrome $c_1$

If a cell-free ox heart-muscle suspension is washed ith acetate buffer ($p$H 4·6) and phosphate buffer H 7·5) and then treated with succinate and cyanide shows, according to Yakushiji and Okunuki[23,24], in dition to the absorption bands $a$ and $b$, a band at 2 mμ. They ascribed this band to the presence of new cytochrome component which they named tochrome $c_1$. In a normal heart-muscle prepar- tion they could not distinguish this component om cytochrome $c$. Cytochrome $c_1$ was separated y them from other components of cytochrome y extracting a heart-muscle preparation with dium cholate, fractionally precipitating the extract ith ammonium sulphate and dissolving the opropriate fraction in phosphate buffer $p$H 7·3. he main properties of cytochrome $c_1$ as given by ese workers can be summarized as follows. (1) In e reduced state it shows three absorption bands: 552, β-522 and γ-416 mμ; on oxidation the γ-band is shifted to 410 mμ. (2) It is not autoxidizable, but is rapidly oxidized by ferricytochrome $c$ or by a mixture of 99·25 per cent potassium ferrocyanide and 0·75 per cent potassium ferricyanide, which indicates that its oxidation-reduction potential lies between those of cytochrome $b$ and cytochrome $c$. (3) On treating this component with pyridine and sodium dithionite, its α-band shifts from 552 to 550 mμ, which is the position of the α-band of cytochrome $c$. (4) A similar compound can be obtained from heart muscle of other mammals, *Acetobacter pasteurianum*, baker's yeast, a red alga *Porphyra tenera*, and from other organisms.

The position of cytochrome $c_1$ in the electron transfer chain was represented by Yakushiji and Okunuki as follows:

$$\begin{tikzcd}
O_2 \arrow[r, dash] & \text{Cytochrome oxidase} \arrow[r, dash] & c \arrow[d, shift left] & c_1 \arrow[l] \arrow[dl] & b \arrow[l] \arrow[r, dash] & \text{succinic dehydrogenase} \\
 & & a \arrow[u, shift left] & & &
\end{tikzcd}$$

Our suggestion[7] as to the possible identity of cytochrome $c_1$ with the BAL (2:3-dimercaptopropanol)-sensitive factor[21], which forms an important link between cytochrome $b$ and cytochrome $c$, was not confirmed by Slater[22]. He repeated Yakushiji and Okunuki's experiments and also obtained their type of preparation, with the band at 552 mμ, from a heart-muscle preparation treated with BAL, which irreversibly destroys the 'factor'. We have re-examined this BAL-treated heart-muscle preparation and conclude that, since the wave-length of its $c$-band (551·8 mμ) is virtually identical with that shown by a normal preparation, the BAL treatment does not destroy the component responsible for shifting the α-band of cytochrome $c$ from 550 to 552 mμ. Furthermore, Slater[22] could find no clear evidence in support of the existence of cytochrome $c_1$, and he explained the position of the absorption band at 552 mμ as being due to displacement of the α-band of cytochrome $c$ by the presence of a band due to the denatured protein protohæmochromogen in such preparations.

Having repeated the experiments of Yakushiji and Okunuki and, by a similar method, obtained their cytochrome $c_1$ (Fig. 3), we were able to corroborate their main observations. The similarity in properties of cytochromes $c_1$ and $e$ described above strongly supports the view that these two components are identical. We have reached this conclusion despite the fact that the band positions given for cytochrome $c_1$ (α-552, β-522, γ-416 mμ) do not agree closely with those that we have found for cytochrome $e$ (α-553, β-524, γ-418 mμ). These differences are, however, very small and may be due either to the presence in their material of a small amount of cytochrome $c$ or to the fact that their spectrophotometric equipment lacked the precision of modern photoelectric instruments. While it is true that in attempting to follow the incompletely described method for preparation of cytochrome $c_1$ we obtained material containing protein protohæmochromogen, we do not believe that its presence could bring about a shift of the α-band of cytochrome $c$. Our analysis of the mutual interference to be expected from neighbouring absorption bands can be extended to show that the α-band of such a hæmochromogen, which would lie at about 558 mμ, could not bring about an apparent shift of 2 mμ in the position of a markedly stronger α-band of cytochrome $c$. On treating a solution of cytochrome $c_1$ with sodium hydroxide (0·1 $N$), pyridine and sodium dithionite, its α-band shifts to 550·4 mμ and the absorption spectrum is then indistinguishable from that of cytochrome c treated in the same way. Similar changes in the α-band of cytochrome $c_1$ are obtained when a cytochrome c - deficient heart-muscle preparation is warmed to 70° and reduced with sodium dithionite. It is conceivable that cytochrome $c_1$ occupies an intermediate position between cytochrome c and a more primitive protohæmochromogen precursor. However, problems involving the relationship between structure and absorption spectra of hæmoproteins must await solution until the reactions of hæms and hæmoproteins with different substances are better understood[33]. Since cytochromes $c_1$ and e appear to be identical, the term cytochrome e, proposed in 1949, should be replaced by cytochrome $c_1$, which was introduced in 1940. Furthermore, the designation $c_1$ more clearly indicates the relationship of this component with cytochrome c.

## Summary and Conclusions

(1) It is known that the extracted, soluble or exogenous cytochrome c differs in some of its properties from the endogenous form present within cells or cell-free preparations. That these differences do not reflect any marked change in the structure of cytochrome c during its extraction and purification is indicated by the ease with which extracted cytochrome c can be re-incorporated into cytochrome c-deficient heart-muscle preparations, after which it appears to re-acquire the properties of the endogenous pigment originally present in the preparation.

(2) The difference in the absorption spectra of these two forms of cytochrome c in the reduced state is of special interest since it has now been shown to depend upon the presence within cells or cell-free heart-muscle preparations of another component of cytochrome the α-band of which fuses with that of cytochrome c (550 mμ), forming a single band with a maximum at 552 mμ.

(3) This additional component is the cytochrome $c_1$ of Yakushiji and Okunuki[29,30], which we now identify with a component formerly described by us as cytochrome e [21].

(4) The evidence for the existence of cytochrome $c_1$ (= cytochrome e), which is based upon the study of absorption spectra at low temperatures, the displacement of the α-band of cytochrome c when it forms part of a complete cytochrome system and the isolation of component $c_1$ virtually free from other cytochrome components, can be summarized as follows.

(i) The α-band of cytochrome $c_1$ can be easily seen together with all other components of the cytochrome system in cells and cell-free heart-muscle preparations suspended in aqueous glycerol and cooled to the temperature of liquid air. It is the great sharpening of absorption bands at very low temperatures that resolves the fused α-bands of cytochromes c and $c_1$ into two distinct bands with peaks about 3 mμ apart.

(ii) The α-band of cytochrome $c_1$ can be seen at 553–554 mμ in a heart-muscle preparation made deficient in cytochrome c and reduced with ascorbic acid.

(iii) In an optical mixture of the reduced cytochrome c - deficient heart-muscle preparation and reduced soluble cytochrome c, the α-band of the latter is displaced from 550 to 552 mμ.

(iv) On the other hand, the α-band of endogenous cytochrome c (which represents a mixture of those of cytochrome c and cytochrome $c_1$) is shifted from 5 to 550 mμ when cytochrome $c_1$ is either denatured oxidized.

(v) A preparation of cytochrome $c_1$, rendere soluble by means of sodium cholate, has been isolat from heart muscle. It shows absorption maxima 553 (α), 524 (β) and 418 (γ) mμ.

(5) It has been shown that two absorption ban even as sharp as the α-band of cytochrome c cann be resolved spectrophotometrically if their maxim lie 4 mμ or less apart. However, two such ban with maxima only 3 mμ apart can be easily resolve if the bands are made much sharper by cooling th material to the temperature of liquid air.

(6) Contrary to the view put forward by som workers[28], cytochrome $c_1$ (= cytochrome e) is n identical with cytochrome $b_2$. These two component show marked differences in their localization withi cells, in their absorption spectra, in their reactio with biological reducing systems in presence and i absence of antimycin A, and in their reactions wit oxygen.

(7) Cytochrome $c_1$, like cytochrome c, is n autoxidizable, and its reduction by the succini dehydrogenase system or by DPNH (reduced c enzyme I) is inhibited by narcotics and by antimyc A. It reacts neither with carbon monoxide n with cyanide. Unlike cytochrome c, but like oth components of cytochrome, it is thermolabile an more intimately linked with structural elements the cell.

(8) Cytochrome $c_1$ (= cytochrome e) is a widel distributed component forming an integral part the intracellular electron transfer chain betwe activated molecules of substrate and oxygen.

We wish to thank Dr. F. M. Strong for a generou gift of antimycin A.

## Function of the Bower of Bower-birds

There exist two widely divergent and irreconcilable theories concerning the nature and function of bower-building in bower-birds (Ptilonorhynchidae). The first, which may be called the traditional view, finds s expression in numerous writings (references in Marshall[1,2]) which describe bower-birds as intelligent and consciously æsthetic (in the human sense of the xpressions) in their collection of colourful display-things and in bower-building. This view involves lso the stated belief that bowers are built for recrea-onal purposes and are little concerned with reproductive processes, even though the latter may have accounted for the origin of display in the early history of the species.

The second view is that the bower and display-round form the centrepiece of the male bird's territory, and that to it is attracted a female to which the male displays (sometimes for several weeks) until the environment, and next the female's internal exual processes, come seasonally to a state appropriate for successful reproduction, after which copulation occurs. Thus, the copulation-date, and hence he ultimate timing of the breeding season, is con-idered to be controlled by environmental factors operating through the exteroceptor organs of the female.

In advancing the latter hypothesis Marshall[2] has written that it is not yet known what are the events that "cause sudden transference of the physical attention of the male from his display-things to the . . female which has been waiting alongside for so many weeks".

Observations made by me in the Cordeaux River area, south-eastern New South Wales, on October 2, 1954, perhaps supply these missing data.

A blue-black male satin bower-bird (*Ptilonorhynchus violaceus*) came to its highly decorated display-ground, renovated the bower, painted its walls (with charcoal mixed with saliva) and then flew to a tall *Acacia* tree near by, where he repeatedly produced a long-drawn territorial whistle for about half an hour. A female now came to the bower and, after moving around, went to the central avenue at the entrance facing the display-ground. Here she stood. The male then flew down to the display-ground and began to display (Fig. 1). After a few minutes the female assumed the peculiar squatting or flattened crouching attitude, shown approximately in Fig. 2. The male now intensified his performance. The female maintained the crouching position for no less than ten minutes, her only appreciable motion being a rotation of the head as her gaze followed the actions of the male. The male displayed back and forth, holding blue flowers in his beak. Then he moved quickly to the front entrance of the bower where copulation occurred, considerably disordering the bower. The male next departed, and then the female disappeared. Twenty minutes later the male returned and renovated his damaged bower.

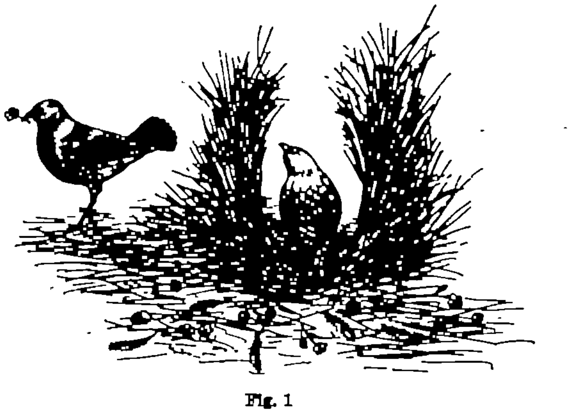

Fig. 1

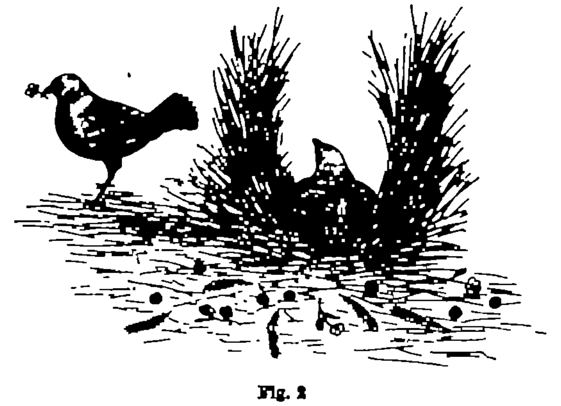

Fig. 2

Although several observers have reported the presence of a single female *Ptilonorhynchus* standing passively watching the displaying male, this appears to be the first occasion on which a female has been seen to strike a special attitude, and the first time, moreover, on which copulation has been observed, although it has been reported at the bower of the spotted bower-bird (*Chlamydera maculata*)[3]. It seems reasonable to suppose that it was the prolonged and peculiar crouching attitude adopted by the female at the bower that released in the male the drive towards coition.

No evidence that polygamy occurs in the above species was obtained. Only one female was seen near the bower; and I have never found more than one nest near a display territory.

A longer account of the present and allied observations will be published in *The Emu*, the journal of the Royal Australasian Ornithologists' Union.

## Aphid Chromosomes

During the early years of this century several workers, notably Morgan[1] and Stevens[2], became interested in the chromosomes of Aphididae, mainly in connexion with their studies on the behaviour of the sex chromosomes and on the phenomenon of parthenogenesis. Shinji[3] wrote on the evolutional significance of the chromosomes of the Aphididae. He investigated some thirty-seven species of American aphids, of which the somatic chromosome numbers ranged from six to thirty-eight, and claimed that the number of chromosomes and the physical characteristics of a species are so closely correlated that the 'evolutional scale' of any aphid can safely be judged from its chromosome number.

Unfortunately, in view of the confused state of systematics and nomenclature of aphids at that time, together with the complete lack of descriptions, no reliance can be placed on Shinji's identifications, even though his general conclusions may retain some validity.

Owing to the recent advances in the study of aphid systematics, a general survey of chromosome numbers on the lines attempted by Shinji, but with reliably identified species, is now possible and is being conducted. This should provide interesting information on the evolution of Aphididae, and it is hoped also that new light will be shed on some of the problems connected with speciation, hybridization, the initiation of wing production in the viviparous generations, and the production of the sexual forms.

For several reasons it has been found best to work with diploid material. Though testis material would provide large numbers of dividing nuclei in suitable stages, and the counting of haploid numbers would be easier, in practice it is impossible to identify with sufficient certainty the naturally occurring male aphids in the early instars which alone are of use. Spermatogenesis is completed in the nymphal stages, and adult males contain only mature sperms. The use of males is further limited by the short period of the year during which they are obtainable. Hence, smears are made of the body contents of viviparous parthenogenetic females. These females are readily identifiable and, in addition to being available in large numbers from spring to autumn, can in many cases be cultured indoors during the colder months.

The advanced embryos removed from mature viviparous females themselves already contain parthenogenetic ova and embryos in the early stages of segmentation, and it is in these early cleavage divisions that the largest chromosomes are to be found. Even here, however, the average chromosome size during metaphase is only about 1μ, and the diameter of the metaphase plate is about 4μ.

Because of the small size and close approximation of these chromosomes, only the very best prophase and metaphase figures can be used for reliable counting and comparison. As such figures are relatively scarce in the preparations, large numbers of smears are necessary. Temporary preparations, though occasionally useful, are not suitable for mass production and lengthy examination, so permanent slides are the rule. Fixation and staining must be of high quality, and though many techniques have been tried, the best results have been obtained from permanent smears fixed in osmic acid and stained with crystal violet or by the Feulgen method.

The somatic chromosome numbers of the species of aphids so far investigated are multiples of four; for example, in *Aphis fabae* Scop., *Aphis rumicis* L., *Aphis viburni* Scop., and *Acyrthosiphon pisum* (Harris), $2n = 8$; in *Brachycaudus prunicola* Kltb., *Hyperomyzus lactucae* L., *Myzus persicae* (Sulz.) and *Pachypapella reaumuri* Kltb., $2n = 12$; and in *Brevicoryne brassicae* L., $2n = 16$.

Although the examples quoted are insufficient to show any general trends, it is obvious that the possession of the same chromosome numbers is not necessarily an indication either of close morphological relationship or of 'evolutional' affinity, despite Shinji's assertion to the contrary.

On the other hand, it appears that very clos allied forms, as, for example, members of the *Ap* *fabae* 'complex', a few of which have been investigat do have the same chromosome numbers. Furt comparison of such forms must be conducted on t basis of the relative sizes and shapes of individ chromosomes.

## Regeneration of the Filtrable Forms of *Salmonella enteritidis* in Media containing Blood Plasma (Fibrin Structure)

THE experiments to be described were conduct with the purpose of attaining a more extensive generation of filtrable forms by modifying t technique. In analogy with the use of blood plasm in tissue cultures, we also added blood plasma media for regeneration, as it was thought th granules capable of regeneration would be adsorb on the submicroscopic network of fibrin, creati thereby more favourable conditions for assimilati processes than would be brought about had t granules settled to the bottom of the tubes.

In these experiments 'regeneration' was understo to mean growth through intermediate forms, aft a period longer than 72 hours in media enriched wi native proteins, as compared to the sterility of t control media.

There were three series in which filtrable forms we obtained partly by ageing of the cultures and part by exposure to a sublethal dose of penicillin[1]. Filtr tion was through Seitz *S* filters at a negative pressu of 10–15 mm. mercury for about 10–15 min.

One part of the filtrate was then centrifuged 9,600 r.p.m. for 45 min. in an angle centrifuge (Vif Stockholm, type *B*). This was done for the followi reasons: (1) to obtain an inoculum containing unusually high number of filtrable forms per un volume; (2) to make the sterility tests even mo

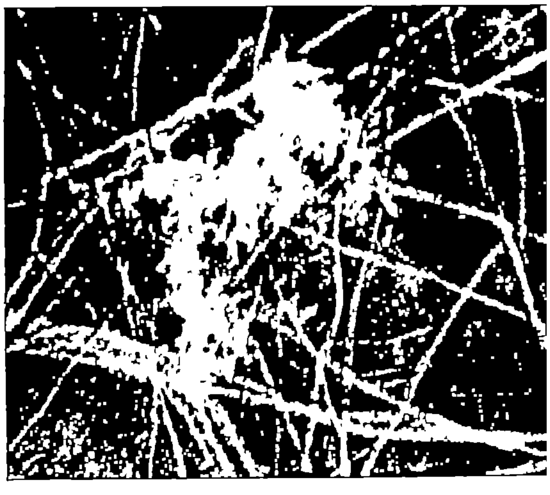

Fig. 1. Granules from the filtrate on the fibrin network. (Th electron micrograph was taken by M. D. Egyessy, of the Electron Microscope Laboratory, Hungarian Academy of Sciences, t whom we express our thanks)

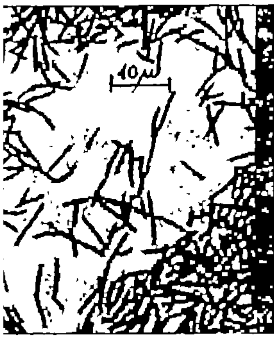

Fig. 2. Atypical *Salmonella* regenerated from filtrate

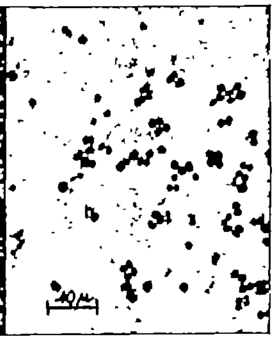

Fig. 3. Polymorphous culture of cocci grown from filtrate

luable and convincing. It is obvious that even only a few bacteria pass through the filter, they will easily detectable in the sediment; (3) to obtain preparation which is pure and concentrated for ctron microscopic studies.

The inocula were: the filtrate, the sediment and e supernatant fluid obtained by centrifugation. ch of these was inoculated into the following dia: (*a*) serum broth; (*b*) serum broth containing proximately 5 per cent chicken plasma; (*c*) comnly used media for sterility tests aiming at tecting the eventual presence of *Salmonellae*.

In none of the control media could we demonstrate e growth of *Salmonella* or any related organism. To avoid subsequent contamination, the closed bes were kept in an incubator at 37° C. and reained unopened until cloudiness or formation of a posit visible to the naked eye could be seen in em.

Irrespective of the method used for inducing trable forms (ageing or penicillin treatment), the edia containing blood plasma proved to be superior serum broth so far as the reversion of filtrable forms microscopically visible forms was concerned. In edia enriched with plasma, regeneration was more arked, and the cultures grown in them resembled e initial strain more closely than those grown in rum broth. Moreover, complete reversion to the itial strain resulted exclusively in the serum broth ntaining plasma in the above experiments. The verted strains were identified on the basis of rphological appearance, fermentation and serogical (agglutination) tests and ouse pathogenicity.

Regeneration took place in thiren of a total of fifteen plasma ltures; of these, complete rersion occurred in two cases; cillary cultures differing mainly rologically and pathologically m the original *Salmonella* strain ose in six cases; polymorphous lture consisting of coccoids and ds in one case; coccoid cultures four cases and only in six of total of fifteen serum broth ltures (yielding all coccoid cultres).

Further experiments are necessary to elucidate whether the role fibrin in the process of regeneran as a network is a purely chanical one or whether it has chemical implications as well.

As in similar experiments by other workers, in the series reported upon here, evidence was obtained to show that bacterial life-cycles exist and that bacteria are extremely variable. It appears to be beyond doubt that in many cases the transformation of bacteria will take place through filtrable forms.

## Manganese Requirement and Carbon Source in *Chlorella*

Photosynthesis of unicellular green algae (*Chlorella*[1], *Ankistrodesmus*[2], *Scenedesmus*[3]) requires the presence of small quantities of the micronutrient manganese ($Mn^{++}$). Manganese-deficient cells show a much-reduced photosynthesis, which can be rapidly brought to normal by addition of manganese (short-term recovery effect). This effect of manganese has been shown to occur both in strong and in weak light[2,3].

During a comparative examination of the mineral requirements of auto-, hetero- and mixo-trophically grown *Chlorella vulgaris*[4] the role of manganese has also been followed. As Fig. 1 shows, manganese deficiency (manganese being omitted from the solution, which was not specially purified) has no influence upon growth in green heterotrophic culture in darkness (1 per cent glucose, air + 3 per cent carbon dioxide); however, cells of this culture show an inhibited photosynthesis in light and give the well-known recovery effect. Cells cultivated autotrophically and mixotrophically (glucose + light) are strongly inhibited in their growth by manganese deficiency. In mixotrophic cultures the glucose is not completely used up. If transferred to darkness, the manganese-deficient mixotrophic cells continue glucose consumption and growth. Conversely, growth and glucose consumption are stopped when heterotrophic cells from manganese-deficient cultures are transferred from darkness into sufficiently strong

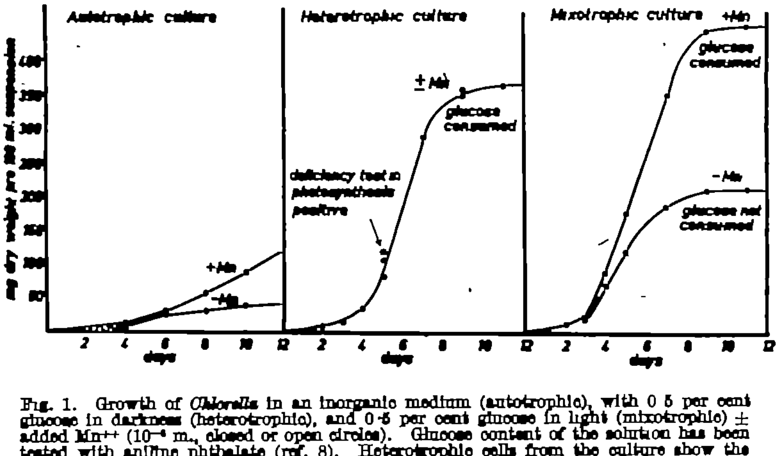

Fig. 1. Growth of *Chlorella* in an inorganic medium (autotrophic), with 0·5 per cent glucose in darkness (heterotrophic), and 0·5 per cent glucose in light (mixotrophic) ± added $Mn^{++}$ ($10^{-4}$ m., closed or open circles). Glucose content of the solution has been tested with aniline phthalate (ref. 8). Heterotrophic cells from the culture show the typical photosynthetic symptoms of manganese deficiency, when transferred to light at the time marked by the arrow

light. The question why mixotrophically grown manganese-deficient cells in the light are prevented from adopting the heterotrophic form of nutrition is being explored at present. The available data suggest a photometabolism of glucose, which is different from that in darkness, and which is linked to the photosynthetic apparatus of the cell[3]. Other results obtained with normal and deficient cells point in the same direction[4].

Whether the photometabolism of glucose can be compared with the consumption of organic material by green and purple bacteria[5] during anaerobic photosynthesis must be further studied. *Chlorella*, which has been grown anaerobically without carbon dioxide but with glucose in the light[7], proves, according to our observations, to have the same requirement of manganese as autotrophic and mixotrophic cultures. Manganese deficiency manifests itself in all the cases examined, where the cells make use of their photosynthetic apparatus.

## Genetics of Endosperm

In *Trillium grandiflorum* and other species of the same genus, cold treatment reveals differences between homologous chromosomes with regard to number and/or length of heterochromatic segments[1]. In our experiments, differences have been found in the $B$-, $C$- and $E$-chromosomes (Figs. 1, 2$A$). According to the number and length of these segments, the following types of chromosomes have been distinguished: $B_1$, $B\frac{1}{2}$, $C_1$, $C_2$, $E_2$ and $E_3$ (where the suffixes give the number or length of the heterochromatic regions).

In order to learn how eu- and heterochromatic blocks are carried over into daughter plants, crosses between individuals of *T. grandiflorum* differing in the structure of homologous chromosomes have been made (for example, $C_1C_2 \times C_1C_1$).

Fig. 3 illustrates the embryo sac development of *T. grandiflorum* and the possible ways of distribution of the homologous chromosomes $C_1$ and $C_2$ in the cross $C_1C_2 \times C_1C_1$. It will be evident that the chromosomal differences in *T. grandiflorum* may serve as markers in a 'tetrad analysis' if endosperms are used as $F_1$-progeny. All $C_1C_1C_1$- and $C_1C_2C_2$-endosperms are the product of a first-division segregation, whereas the $C_1C_1C_2$-endosperms arise as the result of a second-division segregation of the heterochromatic region (Fig. 2$B$).

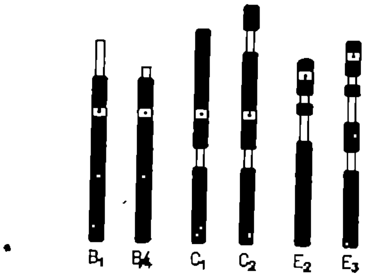

Fig. 1. Chromosomes of *Trillium grandiflorum* (euchromatin in black, heterochromatin in white; centromere region dotted). × 5,000

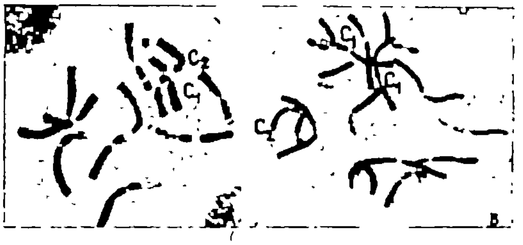

Fig. 2. Chromosomes of *Trillium grandiflorum*, × 800. ($A$) Metaphase from a cold-treated root tip, ($B$) metaphase from a cold-treated endosperm of the cross $C_1C_2 \times C_1C_1$ ($C_1C_1C_2$ indicating second-division segregation)

In our experiments, all three types of endosper occurred (see Table 1). In agreement with expecta tion, the ratio of the two types of first-divisio segregation, $C_1C_1C_1$ and $C_1C_2C_2$, was found to b around 1 : 1. The frequencies of second-divisio segregation, of type $C_1C_1C_2$, proved to be fairly hig ($x = 37$, $y = 28$, $z = 42$). Mather[2] has shown tha in the absence of interference, the frequency c second-division segregation approaches a randor value of 2/3 when the distance between the centrc mere and a given locus becomes large. In two case our experimental data do not deviate significantl from this theoretical value ($P_x < 0{\cdot}2$, $P_y < 0{\cdot}3$). I the third case, however, the observed proportion c second-division segregation is significantly highe

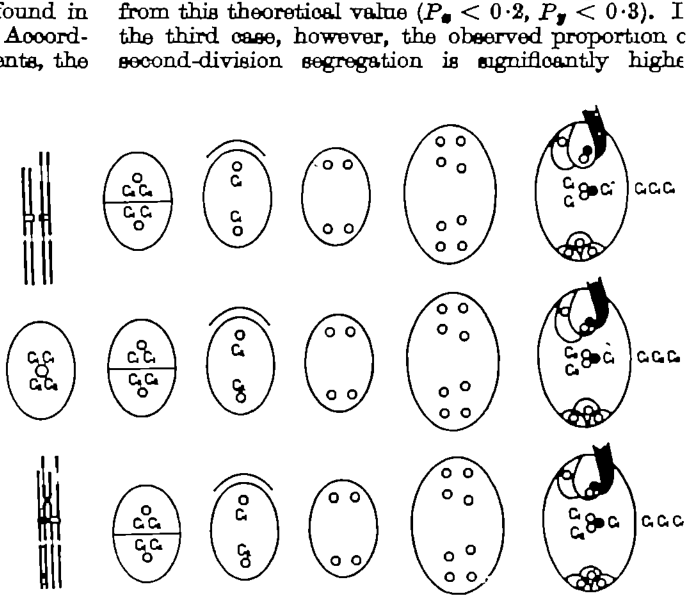

Fig. 3. Illustration of embryo-sac development in *Trillium grandiflorum* (*Allium*-type), showing distribution of homologous chromosomes (sperm nuclei and pollen tubes shown in black)

## Influence of the Origin of the Isolate of *Rhizoctonia solani* on its Pathogenicity

THE fact which has received most attention in nnexion with investigations on the pathogenicity *Rhizoctonia solani* strains is the influence of the igin of the isolate on its pathogenicity. The results these investigations are rather contradictory. hus, Wellman[1], Gram and Webber[2] and others aim that each isolate is most pathogenic to that ant species and its close relations from which it has en obtained. On the other hand, the results ported by Storey[3], Peltier[4], Houston[5], Bosch[6], innasalmi[7] and others seem to oppose this theory of ecificity.

In the present investigation, *Rhizoctonia* strains olated from Ashmouny and Giza '30' cotton rieties, tomato, water-melons, *Phaseolus* and *isum* damped-off seeds and seedlings were used. he different strains were inoculated separately into erile soil in the usual way. Seeds of the different ants mentioned above were sown in soils containing ch of the *Rhizoctonia* strains after adjusting their oisture content to 60 per cent water-holding cap- ity. Controls were kept in sterile soil at the same oisture-level. The containers were incubated at vo temperature-levels, namely, 9°–15° C. and 21°– ° C., for a period of four weeks, during which nergence, post-emergence damping-off and survival ounts were made.

Examination of the results obtained from the high-temperature series showed that: (1) Within the same plant species, for example cotton, isolates obtained from Giza '30' variety showed a striking difference in their pathogenicity from that of Ashmouny. Thus, two isolates obtained from Giza '30' cotton were almost non-pathogenic to tomato and slightly pathogenic to the other hosts. The isolate obtained from Ashmouny cotton, on the other hand, proved to be very pathogenic to the two cotton varieties and *Pisum*. The other three hosts, namely, tomato, *Phaseolus* and water-melon, showed appreciable susceptibility to this isolate. (2) The isolate from water-melon proved to be weakly parasitic, if at all, on the various host plants used. (3) The isolate from *Phaseolus* was very active against water-melon and *Pisum* and moderately active against the rest of the host plants. (4) The isolate from tomato attacked all seedlings of the two cotton varieties and about 60 per cent of the seedlings of *Phaseolus*. On tomato seedlings themselves this isolate proved to be a weak parasite, particularly as a cause of pre-emergence damping-off, although it was quite active as a post-emergence damping-off causal agent. (5) The most active isolate was that of *Pisum*. It destroyed the seedling stands of five host plants completely and the sixth, that is tomato, was badly injured.

The results of the low-temperature series showed that: (1) The pathogenicity of the isolate obtained from Giza '30' cotton, the isolate from Ashmouny cotton and that from water-melon followed, more or less, the same trend as that at high temperature. (2) The isolate from water-melon again proved to be non-pathogenic to the various host plants used. (3) The isolates from tomato, *Phaseolus* and *Pisum* were destructive to all host plants.

The hosts used in this investigation are of very widely separated families of the angiosperms, and yet all, or nearly all, of them were destroyed by several isolates obtained from unrelated plants. This fact supports the view that there is no specificity of the attack of *Rhizoctonia* isolates on the host plants. The facts that the isolate of Ashmouny cotton destroyed the whole stand of *Pisum* seedlings and was only moderately pathogenic at high temperature to *Phaseolus*, which belongs to the same family, and that the isolates of tomato and *Phaseolus* revealed the same effect at both temperature-levels may be taken as circumstantial evidence supporting the view of non-specificity of *Rhizoctonia* isolates.

The results of the present investigation also refute the view that the isolate is usually most active on the plant species from which it has been obtained, since it can be seen from the results of the high-temperature series that the isolates from tomato and *Phaseolus* were more active on other hosts than the respective plants from which they were obtained.

## Apparent Reciprocal Exchange of Characters between the *Mel* and *NWS* Strains of Influenza *A* Virus in the Brain of One-day Old Mice

EVIDENCE has accumulated in the work of Burnet and his colleagues[1,2] that some form of genetic interchange takes place between two strains of influenza virus that have been inoculated into a susceptible host in adequate amounts. However, information about the interaction between the non-neurotropic, *Mel*, and the neurotropic, *NWS*, strains of influenza *A*, which was among the first to be described[1], remained deficient in some important respects.

The recombinant recovered from this system was *N-M* (neuro-*Mel*) virus; but mouse-neuropathogenic *N-M* strains were recovered only from doubly infected mouse brain, not from the infected allantoic cavity of the chick embryo. They were recoverable only after four days had elapsed from the time of intracerebral inoculation[1]. The yield of *N-M* strains from the allantoic cavity was always too small to permit its recovery by direct dilution of the primary product of double infection[3]. No non-pathogenic strain of *WS* serological type was obtained either from the mouse brain or from the allantoic cavity[4]. All this cast some doubt on the mode of origin of *N-M* strains.

In order to investigate these deficiencies, experiments were undertaken to determine how early, after double infection of brain, recombinant strains could be obtained, to find out to what extent neuropathogenicity was transferred at this stage and to search for non-neurotropic viruses of the *WS* type which could be regarded as the 'reciprocal recombinants' to *N-M* in the *NWS* – *Mel* recombination system.

Double intracerebral infection of the one-day old mouse provided a successful method. Such a site of genetic interaction has several disadvantages. The original inoculum is not confined to the site of inoculation[5]; there is no hope of preventing the product of the first cycle of multiplication from being similarly dispersed or from initiating a second reproductive cycle; the cerebral tissue, unlike the allantoic membrane, is heterogeneous and some cells may support the growth of one virus strain better than another. On the other hand, tł unadapted *Mel* strain will grow for at least oı reproductive cycle[6] and the growth of *NWS* ougł to be favoured by this environment.

In spite of these complexities, direct titration ɛ the limit of infectivity of suspensions of braı harvested at various intervals after the inoculatic of approximately $10^{7\cdot6}$ $ID_{50}$ of each strain of virı revealed the presence of virus strains which cou be regarded as reciprocal recombinants of the tw parent strains *Mel* and *NWS*.

Table 1 shows their origin, the time after inoculatic at which they were found and the properties by whic they are ordinarily distinguished. The numbere fluids were obtained by two successive passages ɛ limiting infective dilution from the original suspensic of infected brain, and the properties to which tł table refers were tested on freshly harvested fluic prepared from the numbered fluids by one furth allantoic passage at the limit of infectivity in elever day old chick embryos.

The interesting features of the results are:

(1) Recovery of non-neurotropic virus of the *W* type at a slightly earlier stage than that at whic *N-M*'s were isolated. It is recognizable *in vitro* t some degree of stability against heating at 56° C. fo 30 min. and by its lack of sensitivity, when heate to the inhibiting effect of ovomucin.

(2) *N-M* strains were recovered after 12 hr. I this time it is unlikely that spontaneous mutatıc and selection by the favourable environment ɛ nervous tissue could account for their origin in suc numbers.

(3) The distribution of pathogenicity in the *N-1* strains extended over a wide range, from three straiı which were non-pathogenic to the chick embryo c chorio-allantoic inoculation, but which proved leth intravenously, to two strains which were fully leth for both the chick embryo and the adult mous This distribution at an early stage in the series ɛ reproductive cycles is similar to that of fourth-da fluids and to that obtained for other recombinaı systems by Lind and Burnet[7].

(4) The total yield of recombinants as compare with the proportion in the chick allantoic cavity aı the recovery of a possible *WS* recombinant sugge that the opportunities for genetic interaction ɛ these two strains may vary from one tissue to anothe

Table 1

## A New Species of Sporozoan ?

In the course of research on digestion in *Cardium dule*, Mr. G. Owen, of this Department, noticed tructures, which he termed 'spicules', occurring in he epithelia of the ducts of the digestive diverticula, tomach and midgut. I believe these 'spicules' to be stage in the life-cycle of a coccidiomorph sporozoan, ut can find no account of them in the literature. he following description of them is offered in the ope that if they have already been described I will ceive notice of it.

The 'spicules' are slender cylindrical structures bout 1·5μ in diameter, tapering quite sharply at ne end (the proximal end) and more slowly at the ther. They range in length from 10μ to 50μ and are ound intracellularly, with the long axis perpendicular o the plane of the epithelium (Fig. 1).

The nuclear region (so designated on the strength f Feulgen-positive staining) is situated about one-fth of the overall length from the proximal end, that s, the end in the basal region of the epithelium. The pparent structure of this region varies somewhat, epending on both the state of development of the picule' and the staining method used. In any event seems to consist of a capsule 2–7μ in length con-aining a Feulgen-positive particle or particles 1–4μ in length. The 'spicule' is a little swollen in this region.

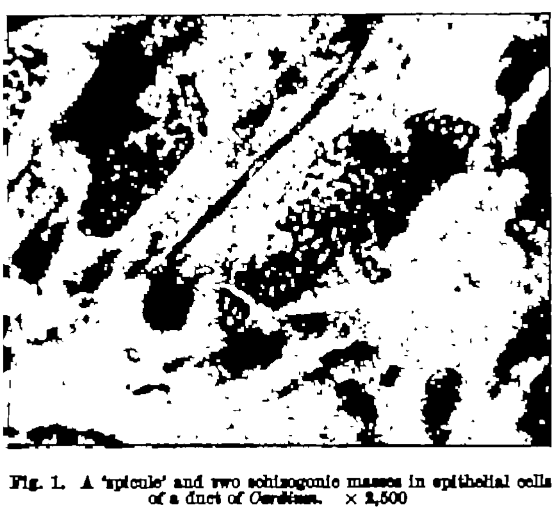

Fig. 1. A 'spicule' and two schizogonic masses in epithelial cells of a duct of *Cardium*. × 2,500

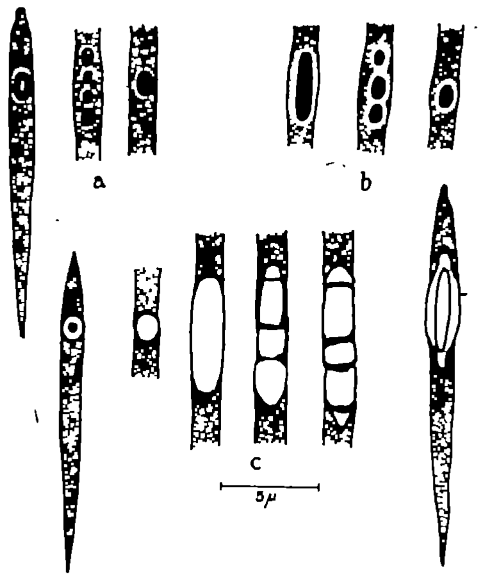

Fig. 2. Appearance of nuclear region produced by (*a*) iron haematoxylin; (*b*) Feulgen; (*c*) crystal violet

Epithelia in the ducts of the digestive diverticula contain many schizogonic masses, in highly hypertrophied cells, besides the 'spicule' stage. These schizogonies make the interpretation of feeding experiments very difficult unless the material fed is quite characteristically distinct from them in staining properties. Still other stages can be seen in the connective tissues and amoebocytes between the ducts.

Practically 100 per cent incidence of infection has been recorded in specimens of *C. edule* from Plymouth, Bangor and Millport. The infection is frequently so heavy that it obliterates much of the epithelium.

A full and complete description of the organism will be published later.

## Glacial Shore-lines

The transition of the shore-line in the neighbourhood of a large ice sheet has been calculated on the assumption that the Earth behaved under the load as an elastic spherical shell enclosing incompressible fluid. The analysis is an extension of that of Niskanen[1], who considered uniformly thick and terraced ice caps, but who calculated the shore-line movement only at the centre, at the edge, and 90° from the centre of these caps.

In the present calculations, the ice load was taken to be that of two polar caps the thickness of which is given by

$$h = h_0 \left( \frac{P_2 (\cos \theta) - P_2 (\cos \theta_0)}{1 - P_2 (\cos \theta_0)} \right)$$

where $h_0$ is maximum thickness of either cap; $\theta_0$ is angular radius of either cap; $\theta$ is latitude of any point on the sphere measured from the North Pole; $P_2$ is a Legendre polynomial of order two.

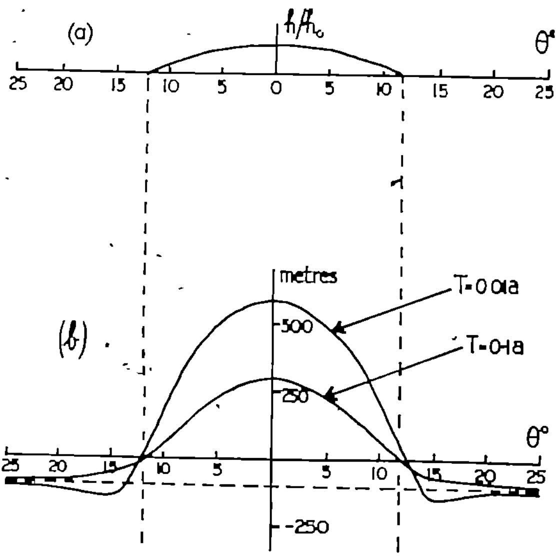

Fig. 1

Fig. 1a shows the shape of the northern cap when θ = 12°.

In order to simplify the problem further, it was assumed (following Niskanen) that where there is no ice there is ocean, and that there occurs in this oceanic region a general or eustatic lowering of the sea corresponding to the abstraction of water to form the ice caps. This removal of water from the ocean affects the elastic solution only very slightly, so that in the final calculation of the shore-line movement one may insert any reasonable value of the eustatic lowering without vitiating the elastic solution. In the present case, the volume of ice in two polar caps of maximum thickness 2,500 m. and of angular radius 12° actually corresponds to a eustatic lowering of only 50 m. over the remaining portion of the Earth's surface.

The transition of the shore-line at any point in the oceanic region was obtained by adding algebraically the four quantities: $U$ (radial elastic displacement of the originally spherical surface of the Earth), $\zeta_1$ (radial displacement of the geoid produced by the elastic displacement $U$), $\zeta_2$ (radial displacement of the geoid produced by the gravitational attraction of the ice cap) and $d$ (eustatic lowering of sea-level). The effect of the mutual attraction of the rearranged water was negligible. A correction to $\zeta_1$ was made to account for the effect of compressibility of the elastic crust.

The rigidity of the crust was taken to be $3 \times 10^{11}$ dynes per sq. cm., the density to be 3·3 gm. per c.c. and the density of the fluid interior to be 4 gm. per c.c. The transition of the shore-line was calculated for the two cases $T = 0{\cdot}1a$ and $T = 0{\cdot}01a$, where $T$ is the thickness of the elastic shell and $a$ is the mean radius of the Earth. In both cases the eustatic lowering accompanying the glaciation was assumed to be 100 m.; Fig. 1b shows the present position of the former glacial shore-line in the northern hemisphere. The glaciated region was not, of course, affected by the eustatic lowering; but if the sea had had access to that area, the present position of the shore would be that shown in the diagram.

It can be seen that, in the area over which there was no ice, there ought now to be raised beaches very near the edge of the former ice cap; but th farther off, the glacial shore-lines should now submerged. For the case $T = 0{\cdot}01a$, the prese depth of these shore-lines increases rather rapid with increasing θ (in the northern hemisphere), un it reaches a maximum at about 300 km. from t edge of the cap. Thereafter, the depth decreases a approaches the eustatic limit (100 m.) from bel and is nearest to that depth on the equator. For $T$ 0·1$a$, the maximum depth of the shore-line is d placed to θ = 30° approximately. It is clear, howev that beyond θ = 45° the departures of the transit from the eustatic limit in either case will be sma and that measurements of the depth of submerg glacial shore-lines made in middle latitudes so to spe will give $d$ fairly accurately. But over a considerab area in the neighbourhood of a former ice cap, t present depth of glacial shore-lines may diff appreciably from that calculated by assuming se level changes there to have been wholly eustatic.

Applying these results to south-west England, f example, and to Devon in particular, which i about 1,600 km. from the centre of the Scandinavi ice cap, we find that the present depth below se level of the glacial shore-line should be either 137 ($T = 0{\cdot}01a$) or 56 m. ($T = 0{\cdot}1a$), both nearly 40 p cent different from the value of the eustatic lowerin

This work was carried out while I was a resear student in the Department of Geodesy and Ge physics, University of Cambridge, and I am indebt to Dr. R. Stoneley for much helpful criticism.

## Slow Disappearance of Fluorescence in Thionine on Addition of Abietic Acid

THE quenching of fluorescence in solution by adde substances is generally regarded as an almost i stantaneous process[1]. We have observed that a quench ing process takes a considerable time for completio affording thereby an opportunity of a very detaile study of the process. If an alcoholic solution abietic acid be added to a solution of thionine i the same solvent, a slow and continuous decrea of fluorescence occurs until it is practically com pletely quenched. The change has been measure fluorimetrically, and a few typical results are repr sented graphically in Fig. 1.

It can be seen from Fig. 1 (curves 1, 2 and 3) tha the higher the concentration of the acid or the dy the more rapid is the quenching. Curve 4 shows tha a higher temperature brings about faster quenchin and curve 5 shows that the medium strongly i fluences the process, $n$-butyl alcohol bringing abou faster quenching than ethyl alcohol.

The most likely explanation seems to be that slow chemical reaction takes place with the formatio of a thionine–abietic acid complex which provide little scope for any intermediate transition to th metastable energy-level responsible for fluorescenc The structures of thionine and abietic acid, howeve do not readily suggest a hitherto known type chemical combination. But the chemical interactio if there be any, must be a very pronounced on since the equilibrium mixture eventually obtaine

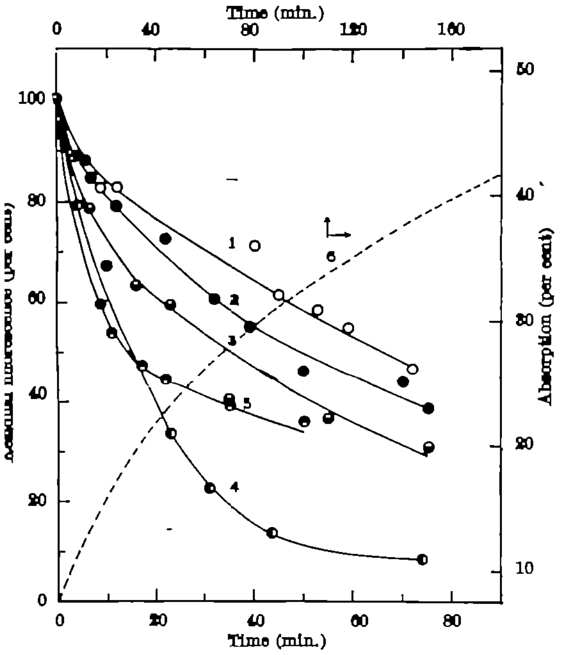

Fig. 1. Change in fluorescence of thionine with time in the presence of abietic acid

| Curve No. | Concentration of thionine ($M$) | Con. of abietic acid ($M$) | Temp. | Solvent. |

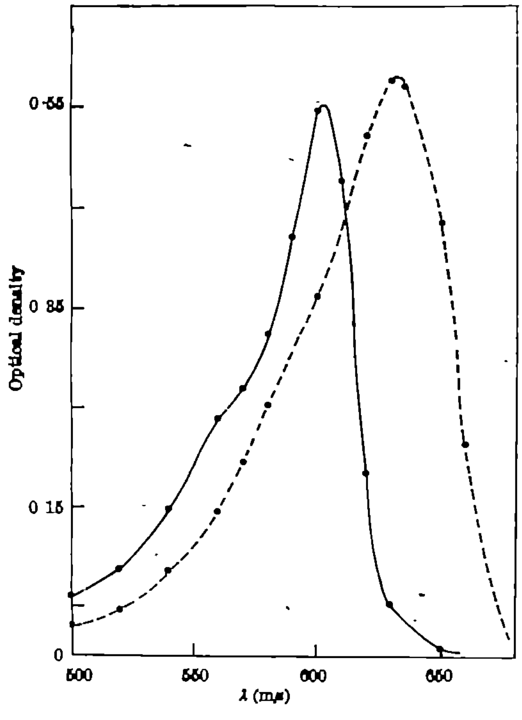

Fig. 2. Change in the absorption spectra of thionine due to quenching by abietic acid. ———, thionine ($10^{-5}$ $M$), max. at 602 m$\mu$; - - - -, quenched thionine, max. at 631 m$\mu$

contains practically no free thionine. On a rough computation, the energy of activation is about 15,000 cal. Moreover, the interaction seems to be highly specific, as a large number of organic substances have been tested by us and found to have no such effect on thionine. Even dihydroabietic acid (differing from abietic acid in one double bond) and its lactone do not quench the fluorescence of thionine. The last observation gives significance to the particular double bond in the abietic acid molecule. Unsaturation, however, is by itself not a factor for quenching, as oleic acid and styrene have been found to be ineffective.

Absorption spectra of thionine in alcohol (Fig. 2) show that, concomitant with quenching by abietic acid, there is also a small shift of about 30 mμ of the absorption maximum towards longer wavelengths. As a result of this shift, absorption is also markedly higher near the new peak, and it is possible to follow the kinetics by measurement of absorption in this region. A typical case of change of absorption with time observed at 635 mμ, which goes parallel with the quenching process, is shown as a dotted curve in Fig. 1 (curve 6).

The above observations thus provide us with a method of studying precisely the kinetics of an addition reaction at extreme dilutions ($10^{-4}$–$10^{-6}$ $M$ or less), and this may have some importance in connexion with biochemical studies involving thionine and similar compounds which are known to affect tissue oxidation and other physiological processes strongly[2]. Also the striking selectivity of abietic acid as described here may be made the basis of a method of its estimation. Detection and estimation of abietic acid have commercial importance since rosin, containing about 85 per cent abietic acid, is very often used as an adulterant to costlier gums such as shellac.

Further investigation is in progress, and detailed results will be published elsewhere.

## Micro-determination of Phosphorus

The increasing application of chromatography to the separation of phospholipids[1] has emphasized the need for greater sensitivity in the estimation of total phosphorus.

Sensitive methods have been described for inorganic phosphate, for example in serum[2], using small volumes of reagents; but they are not readily applicable to the perchloric acid digests obtained in the total phosphorus method, where the volume of acid cannot easily be reduced to less than 2 ml. The method of Allen[3] has proved satisfactory for routine use, but the transference of the digest to a standard flask for development of the molybdenum blue colour results in a final volume of 25 ml. of solution for measurement. The procedure described by Allen for inorganic phosphate in turbid or coloured solutions utilized extraction of the blue compound with isobutyl alcohol, and this principle can be used for simplifying the method for total phosphorus and for increasing its sensitivity about tenfold.

Following digestion with perchloric acid, the colour is developed in the digestion flask as described by Allen and, after 5 min., 3 ml. methyl*iso*butyl ketone is added and the flask shaken for 1 min. To facilitate removal of the coloured ketone layer by pipette, the contents of the flask are poured into a ½-in. diameter test-tube, or the interface is brought into the neck of the digestion flask by adding water saturated with the ketone. The blue colour tends to fade slightly during the first thirty minutes after extraction, but then remains constant for at least one hour and is read during this period.

The calibration curve is linear and passes through zero; 10 μgm. phosphorus gives an extinction of 0·57 at 680 mμ in a 1-cm. cell. As described above, as little as 1 μgm. phosphorus can be estimated; by taking less of the extracting solvent and using micro-cuvettes, the limit could be lowered.

This work was carried out as part of the programme of the Food Investigation Organization of the Department of Scientific and Industrial Research.

## Infra-Red Spectra and the Polymorphism of Glycerides

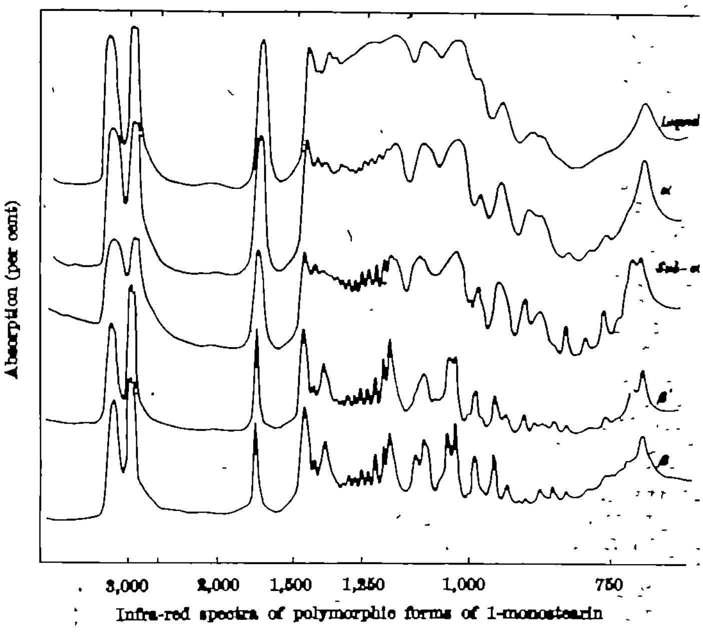
ALTHOUGH it is known that abrupt changes can occur in the infra-red spectra of the crystalline phase when polymorphic transitions occur[1], comparatively little use has been made of this fact to investigate polymorphic changes themselves. The purpose of this communication is to point out that the use of the infra-red technique can be extremely valuable in such cases. The speed of obtaining a spectrum can be useful in those cases where transitions are fairly rapid. Furthermore, information about the molecular structures, for example, hydrogen bonding, etc., can be obtained, and in some cases perhaps even the site symmetry of the molecules in the various polymorphic forms can be deduced.

The polymorphism of some 1-monoglycerides has been investigated using this technique. These glycerides are thought to exist in at least three different forms[2,3], namely, a low melting α-form (vertical rotating chains), two higher-melting forms β′- and β- (inclined chains, alternating melting points). Lutton and Jackson[3] state that the α-form is reasonably stable down to a lower transition temperature, at which point it changes into a new crystalline modification, sub-α, giving a distinctive set of short spacings. Controversy exists over whether the sub-α form is, or is not, crystalline, whether the sub-α α-transformation is genuinely reversible, and wheth the α-form is stable down to the lower transitic temperature.

The infra-red spectra of 1-monostearin in the liqu state and in various polymorphic forms are shov in Fig. 1. These spectra show that quite distinctr differences exist between the various forms. particular, differentiation between the sub-α and t β′-forms is easy, whereas clear differentiation difficult using X-ray powder photographs. T spectra of the liquid, the α- and the sub-α forms we obtained by using a heated infra-red cell *in situ* the infra-red beam. By this means it was possil to observe the transformation of the α- to sub-α for at the transition point 47° C., and the transformati appears to be reversible. The α-form was observ to be quite stable down to this temperature. T spectrum of the α-form indicates clearly that rotati is occurring in this phase, while considerable orient tional freedom is indicated in the sub-α form in t high-temperature regions. An indication of t crystallinity of the sub-α form may be obtained l observing that a band near 720 cm.$^{-1}$ in the α-for is single; but in the sub-α form it splits into tv components.

An analogous situation exists with solid *n*-paraffi in this region of the spectrum. In the liquid state, single band is observed, near 720 cm.$^{-1}$; this bar increases in intensity at the solidification point, ar at a lower transition point two components occu Between the solidification and transition points, t paraffin exists in a hexagonal form, and rotation the hydrocarbon chains about their axes takes plac whereas below the transition point the crystal syste becomes orthorhombic. It can also be compar with the spectrum of polythene, where a band 725 cm.$^{-1}$ is single in the amorphous or liquid stat but double in the crystalline form. The doubling he occurs because of coupling between the two molecul in the unit cell.

Crowe and Smyth, in an investigation of t dielectric behaviour of 1-monoglycerides[4], suggest orientation of various molecular segments in ord



Infra-red spectra of polymorphic forms of 1-monostearin explain the wide distribution of relaxation times erved in the sub-α phase despite the order observed X-ray methods. However, even in the orthombic form of *n*-paraffins, rotation of the hydrobon chains can occur, perhaps even 30 per cent room temperature. This could also occur with hydrocarbon chains of the sub-α form, and would consistent with the sub-α spectrum. The sub-α m was found to be quite stable at room temperae, in agreement with the observation of Lutton l Jackson[3]. The β- and β′-forms were obtained n solvent by slow and rapid crystallization pectively from light petroleum. X-ray and melting nt data were used to confirm the identity of the ms. The spectra of the β′- and β-forms were ained by dispersing the material in 'Nujol'. In the er monoglycerides, for example, monolaurin, the nsformation from the α-form to the final stable orm was followed by means of the spectra.

)ther glycerides (di- and tri-) have been investigated a similar manner and detailed results will be blished elsewhere.

## Strain in 6,8-Thioctic Acid

N 1952 Calvin[1] advanced the hypothesis that the ilable energy of the excited chlorophyll molecule rts photosynthesis by splitting the disulphide ıd of thioctic acid into the biradical. As the ilable energy of the chlorophyll molecule is only 40 kcal. and the disulphide bond-energy lies newhere between 60 and 70 kcal. per mole, this cess would not be possible were it not for the sence of strain in the 1,2-dithiolane moiety of the octic acid molecule. Thus the strain in a 1,2-hiolane ring becomes important.

Recently, Barltrop, Hayes and Calvin[2] calculated strain of 1,2-dithiolane in three different ways. study of the ultra-violet spectra of straight-chain ılphides and 1,2-dithiolanes was used to deduce naximum value of the strain of 27 kcal. mole$^{-1}$ in five-membered ring system. An analysis of the bable structure of dithiolane combined with an imation of the magnitude of different strain factors to a minimum value of 11 kcal. Finally, a kinetic dy of the equilibrium between benzyl mercaptan l 1,2-dithiolane indicated a much smaller value the strain energy, namely, 6·5 kcal. mole$^{-1}$.

From general considerations it seems to be difficult reach a definite decision between the two lower ues of the strain energy. The high value obtained m the spectra should be rejected, because the umptions involved are not very realistic. The uctural analysis ought to be reliable; the method well established and the potential barrier against rotation around the S—S bond seems to be dy well known. The accuracy of the equilibrium investigation may suffer from the fact that the reaction studied is not very well defined.

The most direct way to get information on the energy of the 1,2-dithiolane ring system relative to that of a normal straight-chain disulphide is the calorimetric experiment. We have therefore studied the heat of oxidation of a number of thiols to disulphides, using iodine in 90 per cent ethanol as oxidant. The thiols were used in 20 per cent excess, thus assuring quantitative reduction of the iodine. They were of high purity (better than 99·5 per cent) with one exception, the 6,8-dimercapto-octanoic acid (a gift from Dr. L. C. Gunsalus, University of Illinois), which showed 87 per cent purity—as judged from iodine titrations.

The reaction products were analysed spectrophotometrically. Full agreement with Calvin's results on the 1,2-dithiacyclo-pentane and -hexane was achieved, showing that monomer ring disulphides were the only identifiable products.

The heat equivalent of the calorimetric system was determined electrically and the reproducibility of the measurements was better than 0·5 per cent.

The actual reaction, for which the heat of oxidation was measured, was

$$2\,R.\text{SH (liq.)} + I_2 \text{ (50 ml. 0·1 } N \text{ sol. in 90 per cent ethanol, 10 per cent water)} \rightarrow RSSR \text{ (sol.)} + 2\,\text{HI (0·1 } N \text{ sol.)} - \Delta Hr.$$

The following table gives the results in kcal. mole$^{-1}$.

| Thiol | Disulphide | $-\Delta Hr$ (kcal. mole$^{-1}$) |
|---|---|---|
| 1-Propanethiol | 4,5-Dithiaoctane | 29·85 |
| 1-Pentanethiol | 6,7-Dithiadodecane | 29·85 |
| 1,4-Butanedithiol | 1,2-Dithiacyclohexane | 29·45 |
| 1,3-Propanedithiol | 1,2-Dithiacyclopentane | 25·75 |
| 6,8-Dimercapto-octanoic acid | Thioctic acid | 26·20 |

Taking the heat of oxidation of *n*-propyl and *n*-amyl mercaptans as 'standard' (representing by definition the formation of strainless reaction products), we conclude that under prevailing conditions: (1) the strain in 1,2-dithiolane (parent ring structure) is 4 kcal.; (2) the strain of the substituted 6,8-thioctic acid is about 0·5 kcal. less—in agreement with the fact that substituents stabilize a strained-ring structure; (3) the strain in the six-membered ring 1,2-dithia*cyclo*hexane is on the borderline of significance and probably about 0·5 kcal. mole$^{-1}$.

The small strain in the coplanar—or almost coplanar—1,2-dithiolane structure is difficult to explain from the results of the strain analysis. However, it should be remembered that the strain analysis is valid for gaseous molecules, assuming zero intermolecular interaction. The calorimetric experiments have been carried out in a condensed phase and the conditions for intermolecular interactions may be significantly different for a normal disulphide with a dihedral angle of about 100° and a 1,2-dithiolane ring with the dihedral angle equal to or near zero.

## Autoxidation of Catechin

A MECHANISM is proposed for the autoxidation of catechin to a polymer (catechin tannin) which has for a long time been recognized to have tanning properties.

Empirical study of the fate of catechin at 100° has revealed two interesting reaction processes. In agreement with Freudenberg's interpretation[1] of phlobaphene formation, at $pH < 2$, a buff-coloured phlobaphene, which gave the colour reactions of catechol and phloroglucinol, was rapidly formed both in the presence and absence of oxygen. Between pH 4 and pH 8, however, catechin is autoxidized to red catechin tannin. Autoxidation was arrested by sodium hydrogen sulphite, and only epimerization occurred in absence of oxygen. Catechin tannin had phenolic properties, but it lacked the characteristic properties of catechol and phloroglucinol. Under more alkaline conditions another reaction, possibly ring-fission[2] leading to humic acids, intervened.

Catechin in phosphate buffer (pH 8) was shaken at 35° to constant oxygen uptake; when no catechin could be detected in the paper chromatogram of the reaction mixture, the polymer formed was absorbed on alumina and the hydrogen peroxide in the eluate estimated. The results were: total oxygen uptake 1·59, hydrogen peroxide formed 0·38; oxygen balance, 1·4 moles/mole catechin. Oxygen absorption was represented by a sigmoid curve; but as the rate was slow, namely, 0·0006 mole oxygen/mole catechin/min., an induction period was not detected.

When the autoxidation of catechin in phosphate buffer was followed spectrophotometrically, no intermediate was detected, and the resulting catechin tannin had $\lambda_{max.}$ 400 mμ (pH 6) and $\lambda_{max.}$ 420–430 mμ (pH 8). Silver oxide oxidation of dioxan solutions of catechin and catechol gave compounds of $\lambda_{max.}$ 370 mμ (*o*-benzoquinone ($C_6H_4O_2$) $\lambda_{max.}$ 370 mμ). Catechin tannin was formed when a solution of the corresponding *o*-quinone was shaken with oxygen in phosphate buffer, and by silver oxide oxidation of catechin in phosphate buffer.

It is now suggested that the main reaction sequence involves formation of *o*-quinone followed by oxidative condensation. Formation of *o*-quinone probably involves a free radical mechanism, since the reaction takes place in non-polar solvent. Hydrogen peroxide is associated with quinone formation, and its accumulation results from the difference in velocity of the radical processes, conveniently summarized as:

$$H_2Q + O_2 = Q + H_2O_2 ; \quad H_2Q + H_2O_2 = Q + 2H_2O$$

The autoxidation of polycyclic hydroquinones has afforded unpublished results (D. E. H.), which confirm formation of hydrogen peroxide in oxidations leading to quinones. Autoxidation of catechin is slow, since the oxidation to quinone is inhibited by phenols[3]. Previous evidence[4] for intermediate formation of *o*-quinone includes an attempted isolation of a dianilino-derivative (no analysis or melting point) when tea oxidase acts on catechin. The oxidative condensation is an ionic process requiring dissociating medium, in which addition of phenol to quinone occurs, with CO bond formation between one of the electrophilically activated sites (2′,5′,6′) of the quinone and one of the nucleophilically activated sites (6,8) of another quinone molecule or with the (6,8,2′,5′,6′) sites of a catechin molecule. Addition of phenol to quinone involves transfer of two hydrogen atoms to afford diphenylol, followed by oxidation to the corresponding quinone by means of oxygen, hydrogen peroxide or another molecule of quinone. T oxygen balance agrees with this reaction sequen which permits the formation of a highly irregu three-dimensional polymer, although certain CC bo are excluded on steric considerations. It is signific that since catechol is not bifunctional, it does undergo a similar polymerization. A number catechin derivatives are now being synthesized model substances with which to test these gene conclusions. This reaction sequence has also b postulated to explain the formation of melanin[5] a purpurogallin[6]. It is relevant to a suggestion[7] for formation of condensed tannins in Nature. By action of an oxidase on catechin there results quinone, which is normally reduced by an oxyg acceptor, for example ascorbic acid; but enzy oxidation of *o*-quinone to catechin tannin occ whenever the reduction mechanism is intercept This explanation is similar to that proposed[8] the action of tyrosinase on tyrosine, and the acti of plant polyphenolases on catechin is bei investigated.

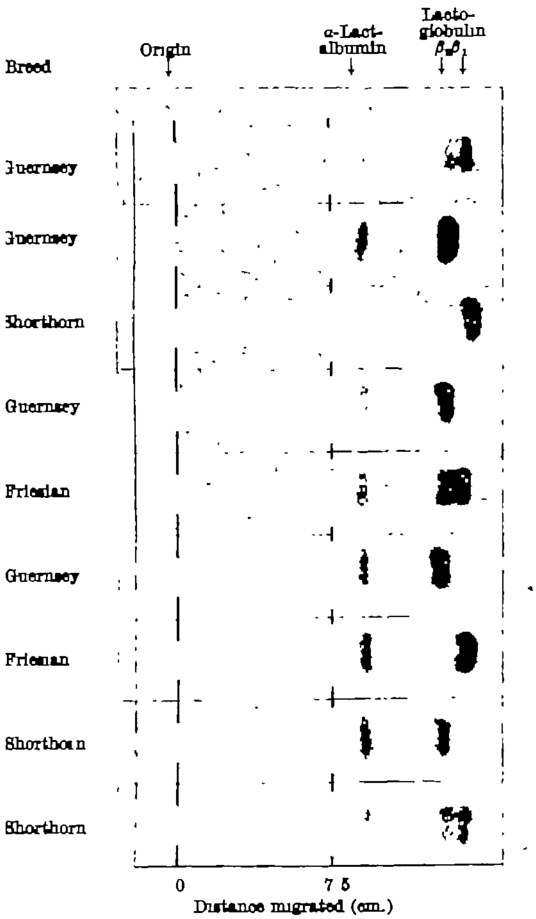
## Occurrence of Different Beta-Lactoglobuli in Cow's Milk

DURING the past twenty years, numerous physic chemical investigations of crystalline β-lactoglobu prepared from cow's milk have revealed a degree heterogeneity puzzling in a protein considered to 'pure' (see the recent discussion of this problem Ogston and Tilley[1]). In general, mixed milk has be used as the starting material, and it has been taci assumed that the β-lactoglobulin synthesized by t mammary gland is the same for all cows. This not the case.

When a suitably prepared fraction of the milk single cows (for example, the proteins soluble 20 per cent sodium sulphate) was subjected to elect phoresis on filter-paper in barbitone buffer at pH 8 $I = 0{\cdot}05$, using an apparatus of the type describ by Flynn and de Mayo[2], and applying 230 V. 16 hr., we found that individual cows produce eith a mixture of two electrophoretically distinct β-lac globulins or only one or the other of these, as sho in Fig. 1, which gives examples of each type. The t single components will be termed $\beta_1$- and $\beta_2$-lac globulin, following the nomenclature suggested Polis, Shmukler, Custer and McMeekin[3], and t mixture of the two in the milk of an individual co



g. 1. The β-lactoglobulins in the milk of nine individual cows (bromo-phenol blue staining)

l be termed $\beta_{1,2}$-lactoglobulin. In most instances, mixture contains more $\beta_1$- than $\beta_2$-lactoglobulin. So far as can be ascertained from our limited trophoretic data for the milk of the same animal mined on different occasions during one, two or ee lactation periods, the type of β-lactoglobulin duced is characteristic for a given cow. Up to the present, 27 Shorthorn, 22 Friesian, 12 Ayrshire and 9 Guernsey cows belonging to the Institute herds have been typed: 30 were found to produce $\beta_{1,2}$-, 7 $\beta_1$- and 33 $\beta_2$-lactoglobulin. The $\beta_{1,2}$- and $\beta_2$-forms were found with all four breeds, but the $\beta_1$-lactoglobulin as yet only in the milk of Shorthorn (3) and Friesian (4) cows. We have also examined the milk of eight sets of one-egg twin heifers. In each set the two animals produced the same type of protein, four sets giving $\beta_{1,2}$-, two $\beta_1$- and two $\beta_2$-lactoglobulin. It thus appears that the synthesis of these β-lactoglobulins is genetically determined; but much further work is clearly required on possible breed or breeding differences.

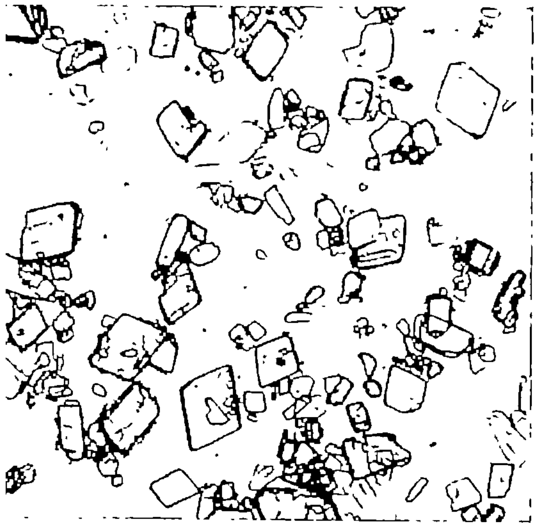


Fig. 2. Crystals of $\beta_2$-lactoglobulin. (× c. 100)

Starting from appropriately selected milks, $\beta_1$- and $\beta_2$-lactoglobulins have been prepared in the crystalline state for investigation of their physico-chemical properties. The crystals were found to be distinctly different; $\beta_1$-lactoglobulin forms rectangular plates indistinguishable from the well-known crystals hitherto prepared from mixed milk, and first photographed by Palmer[4], whereas $\beta_2$-lactoglobulin forms diamond-shaped plates, as illustrated in Fig. 2. The $\beta_1$-component may be identical with the fraction isolated in small yield from the β-lactoglobulin of mixed milk by Polis *et al.* Preliminary results point to other measurable differences between the $\beta_1$- and $\beta_2$-forms, for example, in the isoelectric point and solubility.

Further work on the properties of the isolated β-lactoglobulins and on the occurrence of the various forms in the milk of individual cows, with special reference to twins and to dams and their daughters, is now proceeding.

We are grateful to Mr. N. Gruber for the photographs.

## Action of Insulin on Thiamine Phosphorylation *In vitro*

Previous work has demonstrated that in pancreatic diabetes a disturbance of the thiamine phosphorylation processes occurs and that the administration of insulin enhances the phosphorylation of thiamine provided that a sufficient amount of this substance is available to the organism[1].

It is known that insulin increases the synthesis of adenosine triphosphate and of phosphocreatine in muscle[2] and in liver[3], and thus directly or indirectly influences all phosphorylation reactions connected with adenosine triphosphate or phosphocreatine.

In order to show a direct action of insulin on the enzyme system phosphorylating thiamine, Foa *et al.*[4] studied the effect of insulin *in vitro* by adding this hormone, together with thiamine, to liver homogenates from normal and diabetic rats and then determining the formation of thiamine phosphates. Addition of insulin to homogenates from alloxan diabetic rats enhanced the phosphorylation of thiamine, thus lending weight to the hypothesis that insulin acts directly on thiamine phosphorylation.

Table 1. AMOUNT OF COCARBOXYLASE (µGM./GM. FRESH LIVER) FORMED IN THE INCUBATION MIXTURE

| Incubation | Normal rats | | | Diabetic rats | | |
|---|---|---|---|---|---|---|
| | No. of experiments | No added insulin | With added insulin (1·2 units) | No. of experiments | No added insulin | With added insuli (1·2 units) |
| *A* | 24 | 0·68 ± 0·10 | 0·72 ± 0·11 | 23 | 0·54 ± 0·08 | 0·57 ± 0·11 |

(*A*) Liver homogenate in isotonic potassium chloride solution (1 gm. of tissue + 3 ml. of potassium chloride solution). Incubation mix contains: liver homogenate corresponding to 200 mgm. of fresh liver; thiamine hydrochloride, 100 µgm.; magnesium $2 \times 10^{-3}$ mole; gluta acid 0·2 m.mole; cytochrome *c* $3 \times 10^{-5}$ mole; sodium adenosine triphosphate $5 \times 10^{-4}$ mole; creatine $5 \times 10^{-4}$ mole. Made up to a volume of 4 ml. with potassium chloride solution. Incubation at 38° for 40 min.

(*B*) Liver homogenate in isotonic potassium chloride – potassium phosphate buffer pH 7·5 (1 gm. of tissue + 4 ml. of isotonic soluti the suspension dialysed for 2 hr. against the same buffer. Incubation conditions as in (*A*).

Table 2. AMOUNT OF COCARBOXYLASE (µGM./3 ML. OF INCUBATION MIXTURE) FORMED IN THE INCUBATION

| Incubation | Normal rats | | | Diabetic rats | | |
|---|---|---|---|---|---|---|
| | No. of experiments | No added insulin | With added insulin (0·7 unit) | No. of experiments | No added insulin | With added insuli (0·7 unit) |
| *A* | 18 | 0·26 ± 0·04 | 0·27 ± 0·05 | 20 | 0·20 ± 0·03 | 0·19 ± 0·03 |
| *B* | 20 | 0·24 ± 0·03 | 0·28 ± 0·06 | 21 | 0·19 ± 0·03 | 0·36 ± 0·04 |
| *C* | 20 | 0·31 ± 0·05 | 0·36 ± 0·06 | 22 | 0·20 ± 0·03 | 0·34 ± 0·05 |

Results are means ± the standard error of the means.

(*A*), (*B*), (*C*): Liver thiaminokinase preparations according to Leuthard and Nielsen (ref. 6). Incubation mixture in 0·05 mole potas phosphate buffer, pH 7·4, containing thiamine hydrochloride 50 µgm.; thiaminokinase (dry powder) 3 mgm.; magnesium $2 \times 10^{-3}$ m glutamic acid 0·2 mole; sodium adenosine triphosphate $5 \times 10^{-4}$ mole. Final volume 4 ml. with potassium phosphate buffer.

Insulin was added to the incubation mixture: in (*A*) directly; in (*B*) after incubation at 38° for 30 min. in 0·5 ml. normal rat seru in (*C*) after incubation at 38° for 30 min. in 0·5 ml. diabetic rat serum.

We carried out experiments with liver homogenates under conditions very similar to those reported later by Foa *et al.*[4] (Table 1,*A*), and further work was then undertaken adopting the same experimental conditions as stated by these authors (Table 1,*B*). In neither case could their claims be confirmed.

The discrepancy in the results obtained by us and those of Foa *et al.* may be attributed to a different method in estimating the level of thiamine phosphorylation. While in our experiments cocarboxylase, enzymatically determined[5], has been assumed to be the index of thiamine phosphorylation, Foa *et al.*[4] analysed the materials by means of the thiochrome method, which determines both thiamine mono- and pyro-phosphate. The crude homogenate represents a very complicated enzymatic system, containing many interfering factors, which cannot always be estimated. Even if thiamine phosphorylation were found to be enhanced in such a system, this is not sufficient evidence for a direct action of insulin.

In other experiments, therefore, the action of insulin on thiamine phosphorylation using a much simplified system such as that described by Leuthard and Nielsen[6], which exhibits a strong thiaminokinase action, has been studied. The results of these experiments are reported in Table 2.

The addition of insulin to thiaminokinase preparations from normal and alloxan diabetic livers does not, however, exhibit any positive effects. Thus no significant difference in thiamine phosphorylation between samples with and without the addition of insulin was observed (Table 2,*A*).

Weil-Malherbe and also Bornstein and Park[7] have observed that the presence in blood of factors inhibiting or activating the hexokinase reaction is closely related to the hypophysial and adrenal cortical hormones and also to insulin. Hence further experiments were carried out in which insulin was added to the thiaminokinase preparations after incubation with serum from normal or from diabetic rats (Table 2,*B*,*C*). Little or no effect is observed when insulin, previously incubated in serum, is added to the thiaminokinase preparations from normal rats, whereas cocarboxylase formation is remarkably enhanced when thiaminokinase extracts from diabetic rats are used. This effect of insulin is evident o when the hormone is previously incubated both serum from normal and diabetic animals. Ser itself, without addition of insulin, does not exert a appreciable effect on thiamine phosphorylation.

Since the thiaminokinase preparation used in th experiments is a very purified enzymatic system, may be concluded that insulin exerts a direct acti on thiamine phosphorylation.

Amorphous insulin powder was kindly supplied Eli Lilly and Co.

## Lumi- and Meta-Rhodopsin

ON exposure to light, rhodopsin (visual purple, t photo-receptor pigment of low-intensity vision) changed to lumi-rhodopsin and thence by a therm reaction to meta-rhodopsin[1]. The exact nature these substances is unknown, other than that th consist of retinene (vitamin A aldehyde) joined some way to a protein, opsin. In order to expla the characteristic chemical and spectroscopic b haviour of lumi- and meta-rhodopsin, workers in th field have suggested[1] that one, or both, of lumi- a meta-rhodopsin may be free radicals.

This idea can be investigated by the technique paramagnetic resonance absorption. Free radica are characterized[2] by a line less than 10 gauss wi with a *g*-factor differing from 2·0023, the fr tron value, by only a few parts in the third mal place.

od outer segments from cattle eyes were prepared[2] freeze-dried in dim red light. 51 mgm. of the d powder, containing $1 \cdot 4 \times 10^{-7}$ mole of rhodop- was examined; first, before exposure to light, that containing rhodopsin; again, after exposure to t at 90° K., which converts rhodopsin to lumi- lopsin; and finally, after warming to room tem- ature, to convert lumi- to meta-rhodopsin. In e of these preparations was the resonance line racteristic of free radicals detected, although the itivity of the apparatus used was sufficient to ect considerably less than $10^{-7}$ mole of free radical ie line was as narrow as expected. On the assump- that all free radicals show such a line, it must concluded that neither lumi- nor meta-rhodopsin free radical.

he displacement of the retinene absorption peak 384 mμ to near 500 mμ in rhodopsin, lumi- and a-rhodopsin lacks an explanation. Since free icals cannot be invoked, it is necessary to look a conventional auxochrome linking retinene to tein.

Ve are grateful to Prof. R. A. Morton and Dr. B. aney for their interest and advice.

## -Ray Emission Spectrography using Ion Exchange Membranes

HE spot-test technique of X-ray emission spectro- phy[1] for microgram amounts of elements has been ended to lower concentrations of metal ions by ng ion-exchange resin membranes to concentrate elements present as ions in dilute solution, and ct as a carrier for the sample in the spectrograph. he following technique was employed. Pieces of ion exchange membrane ('Amberplex C-1' cation mbranes, Rohm and Haas Co., Philadelphia, Pa.) n. square were placed in 100 c.c.–1 litre of solutions taining 1–100 μgm. amounts of various cations stirred. It was found that equilibrium was ched in several hours, and the time required ended on the thickness of the membrane. The hange was substantially complete, that is, after ilibrium was established, there were less than ectable amounts of the ion left in solution. Com- e extraction of the metal ion from solution by membrane occurred whenever the exchange acity far exceeded the total amount of the ion in tion. Thus the method is best suited to analysis high dilution.

he following example is illustrative. A piece of 'Amberplex' cation membrane 1·3 cm. × 1·3 × 0·1 cm. in its acid form was stirred with 1 litre solution containing 1 μgm. of cobalt (II) ions (a centration of 1 in $10^9$) for 48 hr. Analysis of the nbrane in the X-ray spectrometer indicated that ad absorbed by ion exchange 1·0 μgm. of cobalt with an error of ± 0·1 μgm. Similar results were obtained using other ions. It appeared that the rate of equilibration was approximately logarithmic, and the half-time for membranes 0·1 cm. thick was about 2–3 hr. Thinner membranes reached equilibrium faster, had a lower background in the spectrometer, and showed less absorption of the characteristic radiation of the several elements measured.

As an illustration of the applications of this method to trace analysis of heavy metals in foods, 100 c.c. of maple syrup was diluted to 1 litre and extracted with a piece of the 'Amberplex' cation exchange membrane. Approximately 0·5 μgm. each of zinc and manganese and 1 μgm. of iron was extracted by the membrane along with lesser amounts of other ions.

When a piece of the membrane was equilibrated with 100 c.c. of a solution containing 10 μgm. of cobalt, and 10 c.c. of versene solution (tetrasodium salt of ethylene diamine tetra acetic acid), the cobalt was retained in solution by the chelating agent. The same reagent removed zinc but not iron from a membrane containing ions of these metals. It was observed also that the equilibration of membranes in 40 per cent sulphuric acid was very effective in reducing the background of all heavy-metal ions present including iron.

We feel that the ion-membrane technique extends the utility of X-ray emission spectrography into new areas beyond the range of previous methods. It can be easily adapted to analyses for anions and to various other studies such as the determination of stability constants of complex ions in solution.

We thank the Rohm and Haas Company for co-operation in supplying some special thin ion-exchange membranes for this study.

## Radio-Frequency Radiation from the Rosette Nebula

A RECENT radio survey of the galactic anti-centre region, made at 242 Mc./s. with the Ohio State University radio telescope, has revealed an intense extended radio source in the constellation of Monoceros. The co-ordinates of the radio source agree closely with the position of the Rosette nebula surrounding the galactic cluster *NGC* 2244. Also the width in right ascension of the radio source is comparable with the diameter of the nebula. Thus, it is presumed that the radio source may be identified with the Rosette nebula.

The antenna of the Ohio State telescope has a half-power beam width of 1·3° in right ascension and of 8° in declination. The right ascension of a source is determined by the time at which the maximum intensity is received, while the declination is determined by comparing records taken at several different declinations. The equivalent angular size[1] of a source is obtained by comparing the beam-width of the source signature with the beam-width for a point source.

The position and angular size of the radio source and of the nebula are compared in Table 1. The total intensity from the nebula is about $2 \times 10^{-24}$ w. m.$^{-2}$ (c./s.)$^{-1}$ (± 25 per cent).

Table 1. (1950·0)

| | R.A. | Declination | Angular diameter |
|---|---|---|---|
| Radio source | 06h. 30·3m. ± 0·5m. | + 5° ± 1° | 1·5° ± 0·5° |
| Rosette nebula (*NGC*2244) | 06h. 30·0m. | + 4° 54′ | 1·33° |

In studies of the Rosette nebula with the 48-inch Schmidt telescope, Minkowski[2] found a fairly symmetrical sharp-edged disk of emission 80′ in diameter around the galactic cluster *NGC*2244. He indicated that the luminosity of the nebula is due to the ultra-violet radiation of four *O*-type stars in the central cluster. According to new data[3], he indicates that the average electron density is about 14 cm.$^{-3}$.

Our radio observations show an apparent black-body temperature over the nebula of approximately 200° K. Assuming an electron temperature of 10,000° K. in the nebula, the average optical thickness at 242 Mc./s. over this region is then 0·02. According to the analysis of Greenstein and Minkowski[4], this corresponds to an emission measure of 3,000, assuming thermal emission by free-free transitions. Considering that the nebula is a Strömgren sphere at a distance of 1,400 parsecs, with a corresponding linear diameter of 37 parsecs, this leads to an average electron density in the nebula of 9 cm.$^{-3}$.

A sketch of the outline of the Rosette nebula in relation to the position of the radio source is presented in Fig. 1. A signature of the radio source taken on February 18, 1955, with the antenna beam directed to Dec. + 6° is also shown.

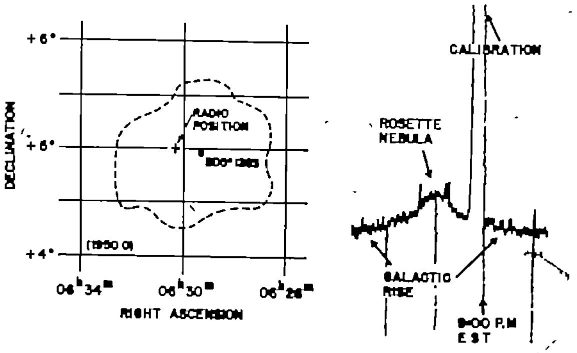

Fig. 1. Outline of the Rosette nebula (dashed line) compared with the radio position (cross); and signature of the Rosette nebula as obtained on February 18, 1955, with the Ohio State University radio telescope

During the survey of the galactic anti-centre region in which radiation was detected from the Rosette nebula, eighteen other intense radio sources were also found. Half of them show angular diameters of 1° or more, and their distribution shows a marked concentration along the galactic plane. A more detailed description of this work will be published separately.

This work has been aided by continuing grants from the Development Fund and the fund for basic research of the Ohio State University, and also by a grant from the National Science Foundation.

## Electron Micrographs from Thick Oxid Layers on Aluminium

The thicker protective coatings of oxide forr
on aluminium by anodizing in acid electrolytes h
long been of importance in industry. The por
nature of these layers has been indicated by tl
electrical and adsorptive properties. Howe
electron microscopic investigation has been alm
entirely confined to extremely thin (less than
oxide layers[1] due to the limitations of the transmis
method of examination. By using the recer
developed evaporated carbon film technique[2], we h
been able to obtain electron micrographs of both
top surface and the cross-section of thick oxide lay
These clearly show the porous structure.

Fig. 1 is a micrograph obtained from the top
face of an oxide layer prepared in 5 per cent chro
acid. The specimen was electropolished 99·99
cent pure aluminium strip anodized at 40° C.,
voltage reaching 90 V. at the end of 100 min.
nitrocellulose-backed 'Formvar' replica was strip
from the surface on scotch tape and a carbon f
evaporated on to it. This was shadowed *in situ* w
gold-palladium alloy at an angle of approximat
20°, the replica then being mounted on a cop
specimen grid and the plastic dissolved away w
organic solvents. The shadowed carbon replica tl
prepared formed a 'negative' of the original surfa
and was examined at a magnification of 12,4
The micrograph has been enlarged to a magnificati
of 25,000. The features shown are regularly
tributed and are those expected from the penetrati
of the replica into a porous surface. 'Carrot'-shap
projections arising from single pores can be discern
In places it appears that the replicated pores ha
merged and their individuality is lost.

Fig. 2 is a micrograph obtained from an ox
cross-section prepared in 17·5 per cent v/v sulphu
acid. The specimen was a strip of electropolish
99·99 per cent pure aluminium anodized at ro
temperature for 60 min. at a current density
50 m.amp./cm.$^2$. The anodized strip was mount
in a moulded block with 'Araldite' casting resin
A cross-section normal to the plane of the oxide s
face was ground on fine emery papers and fina
polished with magnesia on a rotating cloth.
replica was obtained as described above. It
shadowed in the direction of the metal/oxide bound
and examined at a magnification of 10,000. In
micrograph a region at the metal/oxide boundary
shown with the tubular-shaped pores running up
the interface. The parallel alignment of these po
and their orientation normal to the interface
striking. Together with other micrographs obtain

## activity of Freshly Formed Steel Surfaces

It is now an established fact that freshly formed etal surfaces have an inherently high reactivity. probable confirmation of this fact was noticed ently when specimens of mild steel were broken impact at sub-zero temperatures. Fracture was edominantly of the cleavage type at the temperares concerned, and the work undertaken necessited an examination of the fracture surface. It was ticed that this surface corroded far more rapidly an would normally be expected in the laboratory mosphere. Ten minutes after fracture, definite rrosion films could be detected and the well-known st-coloured deposit appeared shortly afterwards.

Undoubtedly the fracture surface would be covered a film of adsorbed moisture and, in view of the cent work on the production of hydrogen peroxide freshly formed metal surfaces[1], it is likely that the idation mechanism was associated with hydrogen roxide formation as suggested by Haber and eiss:

$$H_2O_2 + Fe^{++} \rightarrow Fe^{+++} + OH^- + OH$$
$$OH + Fe^{++} \rightarrow Fe^{+++} + OH^-$$
$$Fe^{+++} + 3OH^- \rightarrow Fe(OH)_3$$

Whatever the corrosion mechanism, the fact remains that freshly cleaved steel surfaces are extremely reactive. The method of cleaving specimens at an appropriate temperature would probably be useful in the investigation of the reactivity of metal surfaces.

## A Method of locating Interfaces in Oil Pipelines

It is often desirable to locate or follow the interface between two oils or fuels during transmission along a pipeline. Present methods include those based upon sampling techniques or radioactive labelling of the interface. The first of these is tedious and slow, and the second method involves the injection of a radioactive marker substance at the interface, with the attendant difficulties of handling radioactive material in the product itself.

An alternative method utilizes the variation of hydrogen content of the two liquids. Hydrogen contents of bulk liquids may be easily compared by the use of a neutron-backscatter or transmission technique. A portable source of fast neutrons can be placed outside the pipe. The neutrons entering the liquid are moderated by scattering from the hydrogen atoms, and the concentration of slow neutrons which emerge from the pipe (either in a forward or backward direction) will be dependent on the hydrogen content of the liquid in the pipe. These can be measured with the use of standard equipment incorporating a boron trifluoride counter.

Preliminary laboratory tests indicate that the measurement of either scattered or absorbed neutrons can differentiate between premium and commercial grade fuels by a 5 per cent change in reading. A further change of 10 per cent occurs between commercial fuel and paraffin.

In the event of the two liquids having the same hydrogen content, if the interface could be labelled with minute quantities of a salt of boron, gadolinium or other suitable material, then it could be located very easily, since these additives absorb the slow neutrons very strongly.

These methods have the great advantage over standard radioactive methods that they do not involve the inconvenience of handling radioactive material in solution, or the necessity of obtaining a regular supply of radioactive isotopes.

The preliminary work carried out on neutron-scattering methods indicates their considerable potentialities, and techniques will be further investigated.

# APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER (Grade II) or SENIOR LECTURER (Grade I) IN THEORETICAL PHYSICS—The Registrar, The University, Bristol 8 (August 6).

LECTURER or ASSISTANT LECTURER IN BOTANY—The Registrar, The University, Birmingham 15 (August 6).

ASSISTANT (preferably with a veterinary qualification) IN THE DEPARTMENT OF VETERINARY PHARMACOLOGY—The Secretary, Royal (Dick) School of Veterinary Studies, The University, Edinburgh (August 8).

RESEARCH DEMONSTRATOR IN PURE MATHEMATICS—The Registrar, The University, Sheffield (August 10).

RESEARCH WORKER (with a university degree, preferably in forestry, and some practical forestry and research experience) to undertake a special study of the problem of planting mining refuse heaps in Scotland—The Secretary, The University, Edinburgh (August 15).

SENIOR LECTURER or LECTURER IN BIOCHEMISTRY at University College, Ibadan, Nigeria—The Secretary, Senate Committee on Colleges Overseas in Special Relation, University of London, Senate House, London, W.C.1 (August 15).

PHYSICIST or MATHEMATICIAN (with a good honours degree in physics, mathematics or equivalent professional qualifications, proved research ability, and preferably experience in strain measurements and/or mechanical properties of materials), at the Central Research Establishment, National Coal Board, Isleworth, to lead a group carrying out research on underground transport of coal—National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting 88/34 (August 16).

BIOCHEMIST (with a Ph.D. degree or equivalent, and preferably with experience in microtechniques) to be a member of a team investigating the growth and metabolism of cells obtained from tumours and from normal organs and grown in culture—The Director, Strangeways Research Laboratory, Wort's Causeway, Cambridge (August 20).

LECTURER IN PSYCHOLOGY—The Registrar, The University, Sheffield (August 20).

ADMINISTRATIVE ASSISTANT (with a scientific degree, preferably in physics, and administrative experience), for work in connexion with the International Geophysical Year—Assistant Secretary, Royal Society, Burlington House, Piccadilly, London, W.1 (August 30).

LUCAS CHAIR OF ENGINEERING PRODUCTION—The Registrar, The University, Birmingham 15 (August 31).

STAFF TUTOR IN SCIENCE in the Department of Extra-Mural Studies—The Registrar, The University, Nottingham (August 31).

LECTURER IN PHYSICS, and an ASSISTANT LECTURER IN PHYSICS—The Registrar, College of Technology, Manchester 1 (September 1).

LECTURERS (2) IN CHEMICAL ENGINEERING, and DEMONSTRATORS IN CHEMISTRY—The Registrar, College of Technology, Manchester 1 (September 1)

ASSISTANT (with a degree in science or agriculture) IN THE CHEMISTRY DEPARTMENT at Auchincruive, for work mainly relating to the analysis of agricultural materials other than soils—The Secretary, West of Scotland Agricultural College, 6 Blythswood Square, Glasgow, C.2 (September 12).

JUNIOR ORGANIC CHEMIST—(with a first- or second-class honours degree in chemistry and two or three years' research experience in organic chemistry) IN THE DEPARTMENT OF SUGAR CHEMISTRY AND TECHNOLOGY, Imperial College of Tropical Agriculture, Trinidad—The Secretary, Imperial College of Tropical Agriculture, 40 Norfolk Street, London, W.C.2 (September 17)

READER IN ZOOLOGY at Royal Holloway College, Englefield Green, Surrey—The Academic Registrar, University of London, Senate House, London, W.C.1 (September 20).

SENIOR LECTURER (preferably with special qualifications in embryology and/or cytology) IN ZOOLOGY at the University of Western Australia—Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, September 30).

BIOCHEMIST (with an honours degree in chemistry or biochemistry, and with one or two years' biochemical research experience), to assist in research work in the Special Unit for Juvenile Rheumatism—The Secretary, Canadian Red Cross Memorial Hospital, Taplow, near Maidenhead

BRITISH NYLON SPINNERS LIMITED RESEARCH FELLOW to work on the structure of wool and nylon staple fibre fabrics—The Principal, Technical College, Bradford 7.

ENTOMOLOGISTS (2) (with a degree in zoology and a sound knowledge of entomology and botany), with the Sudan Government, to carry out a survey of the tsetse areas of the Sudan and undertake research work—The Sudan Agent in London, Cleveland Row, St. James's, London, S.W.1, quoting "Entomologist 2204"

LABORATORY TECHNOLOGIST (with a general degree in science or agriculture, with main interest in chemistry, or an honours degree in chemistry) IN THE DEPARTMENT OF AGRICULTURE, Kenya, to carry out investigational work on problems of agricultural chemistry related to coffee culture—The Director of Recruitment, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting BCD.63/7/09.

PASTURE AGRONOMIST (male, with a university degree in science or agriculture, a special interest in animal husbandry problems and experimental methods used in feeding and grazing trials, and a knowledge of systematic botany to enable ecological surveys to be undertaken) IN THE DEPARTMENT OF VETERINARY SERVICES, Uganda, to conduct feeding and grazing trials, with particular reference to the effect on the animal, and field investigation into the management of grassland systems of grazing and livestock management—Director of Recruitment, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting BCD.67/9/08.

PHYSICIST (with at least a second-class honours degree) to carry out fundamental research work on the behaviour of textile materials as barriers to (a) the flow of fluids, and (b) radiation, including heat and light; and a PHYSICIST (or Chemical Engineer) (with at least a second-class honours degree), to conduct research on the drying of textiles, including fundamental work on the mechanism of drying and applied research on the improvement of old methods and the
development of new—Dr. F. C. Toy, British Cotton Industry Rese
Association, Shirley Institute, Didsbury, Manchester 20.

PRINCIPAL SCIENTIFIC OFFICER (with at least a second-class hon
degree in physics, mathematics or engineering, or equivalent quali
tions) IN THE RESEARCH AND DEVELOPMENT BRANCH of the
Atomic Energy Authority, Risley, to lead a group engaged on
calculation of critical dimensions of plant containing fissile mate
and to advise design offices and factories concerning the safety of
plant—Recruitment Officer, Industrial Group Headquarters, Ri
Warrington, Lancs, quoting "1,049".

SCIENTIFIC OFFICER (honours graduate in chemistry or bioch
istry) to collaborate in fundamental biochemical research, with sp
reference to the synthesis and degradation of isotopically lab
compounds and the application of chromatography and other analy
techniques to their isolation and purification—The Secretary, Nat
Institute for Research in Dairying, Shinfield, Reading, quoting 5

SENIOR EXPERIMENTAL OFFICER (Electronics) (with at least H.
in science subjects or equivalent qualifications, together with
experience of the application of electronics) IN THE RESEARCH
DEVELOPMENT BRANCH of the U.K. Atomic Energy Authority, W
scale, Sellafield, Cumberland, to take charge of a small section eng
on design and construction of various electronic equipment for
chemistry, metallurgy, engineering and physics laboratories—Rec
ment Officer, Industrial Group Headquarters, Risley, Warring
Lancs, quoting "1,048".

SENIOR LECTURER (with an honours degree in mathematics,
preferably with research experience) IN MATHEMATICS—The Princ
West Ham College of Technology, Romford Road, Stratford, Lon
E.15.

SENIOR SCIENTIFIC OFFICER (with a first- or second-class hon
degree in physics, a background of experience in solid-state phy
and at least three years' postgraduate research experience), to
vestigate certain physical aspects of the detonation of solid
explosives and the propagation of intense shock waves through s
and gases—Senior Recruitment Officer, Atomic Weapons Rese
Establishment, Aldermaston, Berks, quoting 709/WGB/2.

# THE UNITED NATIONS AND THE PEACEFUL USES OF ATOMIC ENERGY

N a broadcast address at the end of last year on man's peril from the hydrogen bomb, Lord ussell expressed the opinion that the human race d reached a point when it must abandon war as an strument of policy or accept the possibility of al destruction. It was essential for this to be derstood on both sides of the Iron Curtain, and he ggested that one or more neutral powers should point a commission of experts, all neutrals, to epare a report on the destructive effects to be pected in a war with hydrogen bombs, among utrals as well as among belligerents. This report s to be presented to the Governments of all the eat Powers with an invitation to express their reement or disagreement with its findings. In this y, he thought, all the Great Powers could be led agree that a world war could no longer serve the rposes of any of them, since it would be likely to terminate friend and foe alike as well as neutrals.

The essential point of this appeal—that we must rn to think in a new way because in any future r nuclear weapons will certainly be employed and eir use threatens the continued existence of mannd—is reiterated in a statement made public by rd Russell on July 9. The statement, which was gned by Lord Russell, Prof. P. W. Bridgman, Prof. bert Einstein, Prof. L. Infeld, Prof. J. F. Joliot-rie, Prof. H. J. Muller, Prof. C. F. Powell, Prof. J. otblat and Prof. H. Yukawa, was sent simulneously to Sir Anthony Eden, President Eisenwer, Marshal Bulganin, Mr. Chou En-lai, President ty of France and Mr. St. Laurent, the Prime inister of Canada. The statement concludes with draft resolution which, it is suggested, could be opted by a conference of scientists summoned to termine impartially and without political prejudice e facts about the consequences of exploding nuclear eapons. This resolution urges the Governments of e world to acknowledge publicly that their purposes nnot be furthered by a world war, and consequently find peaceful means for the settlement of all atters in dispute between them.

The resolution is, in essence, a recapitulation, in a w context, of the Kellogg Pact for the renunciation war as an instrument of national policy. Prosals for a conference of scientists received incidental ention in the debates in Parliament on defence rly this year, and in one form such a conference as warmly supported in an outstanding speech by e Archbishop of Canterbury. Much confused inking was evident, however, over the issues volved, nor has the confusion been removed when e proposal has been made in connexion with what popularly known as "Atoms for Peace", though a mposium of articles, including an introduction by rd Russell, contributed to the ninetieth anniversary ue of the New York periodical, *The Nation*, under at title should assist to clarify thought.

The problem of nuclear weapons and their control or renunciation is seen in its true perspective not so much against the special problems of nuclear power and its potentialities for mankind, as against the historical background of such proposals as the Kellogg Pact and the attempts of the League of Nations to achieve disarmament. An understanding of the reasons for these earlier failures illuminates the failure of post-war efforts to achieve a practical scheme for the control of nuclear weapons and may, perhaps, suggest a promising line of advance. Indeed, it will be noted that this new appeal by Lord Russell specifically contemplates an agreement to renounce nuclear weapons as part of a general reduction of armaments.

The celebration of the tenth anniversary of the signing of the Charter of the United Nations at San Francisco appeared to attract little real interest in Great Britain; but a review of the ten years experience of the working of the United Nations may have some value in assessing the usefulness of some of the suggestions made regarding international agreement on atomic energy and in overcoming the difficulties which at present hinder its realization. It should be remembered, moreover, that, in spite of the unique character of the San Francisco Conference, which was attended by delegates of fifty nations, all of whom exercised their vote on the Charter, no extravagant hopes were entertained. There was a sober realization that no international instrument or constitutional specific would suffice of itself to maintain peace.

That much has been fully attested by ten years of what was to be a real regime of collective security under the responsibility of the Security Council, and by a concerted effort under the General Assembly to promote world welfare and particularly that of the lesser-developed or privileged parts of the world. Wherever the Great Powers were prepared to use the Council constructively, the United Nations organization has functioned as an instrument of peace, and to some extent the obstructiveness and negative attitude of the Soviet Union have been offset by the greater readiness of the United States to co-operate and to assume responsibilities of leadership. Moreover, special regional organizations under the ægis of the United Nations have come into being to offset the limitations imposed on the Security Council by the restrictive use of the veto.

On the welfare side, too, there have been disappointments, where the General Assembly and the Special Agencies responsible to it, such as the United Nations Educational, Scientific and Cultural Organization, the Food and Agriculture Organization and so on, have been used irresponsibly or diffusely. As under the League of Nations, the technical organizations have indeed proved far more successful than the political agencies in achieving co-operation and understanding; and for all the disappointments, much more progress has been made by the United Nations as a centre for international welfare than might have been expected ten years ago. However, it must be recognized that some of the important developments have come from outside the United Nations, notably the Point Four Plan of President Trueman, the Colombo Plan for Co-operative Economic Development in South and South-East Asia and the earlier Marshall Aid, from which President Trueman's proposals arose.

At times it has seemed doubtful whether the lessons of military and economic co-operation in the Second World War have been learned. The trusteeship system has proved disappointing, largely through the way in which it has been used by those who bore no responsibility for the consequences of their words. If, however, the hopes originally entertained in regard to research and the encouragement of development have been falsified, much that it was hoped might have taken place under the Trusteeship Council has come into being outside the United Nations; thus a noteworthy advance towards co-ordination and co-operation in research has been made in Africa in this decade. Moreover, even when used irresponsibly, the United Nations and its Agencies have proved a medium for the constant and thorough interchange of thought and ideas which, as wisdom is acquired in their use, should increasingly promote a better and more tolerant understanding among nations and among peoples.

With the work of most of these Specialized Agencies many scientists have been closely concerned, and whatever reservations may be felt about some aspects of the work of the United Nations Educational, Scientific and Cultural Organization, it has probably assisted the International Scientific Unions to function earlier and more widely than might otherwise have happened. It has also contributed notably to the task of creating a world opinion which clearly understands the price to be paid for peace, and the restraints to be accepted as the alternative to anarchy—indeed, the limitations as well as the opportunities of world organization. Such an informed opinion, clearly understanding what is involved, is the first condition for any world organization to function effectively.

If, however, the celebrations at San Francisco on June 26, when all the Great Powers, save China, were represented by their Foreign Ministers, together with those of thirty-four other States, justify greater confidence that this is being achieved, it is probably due less to the work of the United Nations itself than to what has flowed from the advent of nuclear weapons of war. It is not always realized that when the Charter of the United Nations was signed, the atomic bomb was unknown to the world at large, and only slowly have the tremendous implications which nuclear fission may hold for the future of civilization been grasped. That in recent months the nature of the choice which faces mankind has become clear is due at least in part to scientists who have recognized their special responsibilities, in addition to their common rights as citizens, and used their opportunities to let the world know, in the light their intimate and expert knowledge, their views c the uses which the world should make of this gre new gift of science to mankind, and both its promi and its threat to humanity.

The prescience of Sir Henry Dale's observatio in 1945 on this subject, and on the implications nuclear fission and the conditions under which it w achieved, both for science and for humanity, ma in his presidential address that year to the Roy Society, have been amply attested, and many curre proposals might well be considered in their conte The nations have, as Sir Henry remarked, to deci how they intend to use the powers and resourc which science stands ready to offer in growi abundance. Either they must let science work aga and henceforward in freedom, as an internation community, and use what it offers for raising mankind to new levels of material prosperity and culture, or, by binding science to secrecy for th competitive invention of more effective means destruction, they can hold civilization in insta peril of dissolution.

That alternative the Conference on the Peacef Uses of Atomic Energy, opening in Geneva o August 8, may be expected to emphasize, in spite the dominantly technical character of the papers t be presented. Indeed, the range of technical topi to be discussed should of itself demonstrate th importance of full and free discussion for the advan of both science and technology, and help to brea down the secrecy in which nuclear science has bee shrouded and the effects of which are as detriment to science itself as they are to international relatio and understanding between peoples. Nor should be forgotten that scientists are already inquiring int the biological hazards of radiation, and there is n reason for anticipating that, in the present clima of opinion, their findings will not be presented to th world in much the same way that Lord Russell an his co-signatories suggest in respect of nuclear wa fare generally. The Government has already promise to publish the Medical Research Council's report o the subject as a White Paper.

A glance over the ten years work of the Unite Nations thus facilitates sound judgments as to th prospects and possibilities of the recent Geneva Co ference of the Great Powers, of that on Peaceful Uses Nuclear Energy, and of proposals such as Lord Russe and his co-signatories have sponsored, and the simil resolutions passed by eighteen Nobel Prize winne during the course of a meeting held at Mainau o July 15. Of the three broad conceptions which wer to the shaping of the United Nations and i activities, it is fair to say that only one—that of th United Nations as a centre of economic and techn logical activity—has stood the test of this decad The hopes for the organization as a body boun together by the observance of certain standards international decency have, by and large, prove illusory, as also those of it as an attempt t "put teeth into the Covenant of the League Nations".

But even these two conceptions have not been ite without value. In certain conditions, the ited Nations is clearly capable of keeping the ace, and, given agreement and mutual undernding between the two great blocks of nations, it ild largely achieve its declared purposes. It is ially clear that such agreement does not yet ly exist, in spite of the Geneva Conference. The rld would indeed be in much worse shape without e United Nations, which remains as a place where e two great power blocks and those who try to be utral can come together to find ways of reconciling eir different outlooks before it is too late.

Nor is this all. There is some evidence, and not ast in the talks at the recent Four-Power Conferce at Geneva, that some international standards e gaining wide acceptance, at least to the extent lip-service if not actual practice. That process ight be encouraged if there were less disposition to critical, and if the critics were more careful that eir own practice matched the standards they lvocate. Co-existence implies tolerance; but what required above all is realism—a clear recognition what the United Nations can, and cannot, do.

Two positive aspects in particular seem important considering appeals such as Lord Russell and hers have launched. The United Nations, as has ist been indicated, has demonstrated its value as a rum for the discussion of international problems id the creation of world opinion. This is a slow rocess; but it is important that all that is posle should be done to assist and accelerate it. econdly, the United Nations and its Specialized gencies have demonstrated their value as a potential rce for the dissemination of technical knowledge nd assistance. Their effectiveness in that respect ill be increased as they are more wisely used, and s greater care is taken to increase the efficiency with hich such non-political activities are organized.

Lord Russell's appeal does not appear to show ill cognizance of this position. In thanking Lord ussell for his letter, the Prime Minister wrote that e agreed that only the abolition of war could finally emove the perils which threaten the future of manind, and welcomed the recognition in the statement hat it is war itself and not simply nuclear weapons hich must be abolished, and that the renunciation f nuclear weapons must form part of a general eduction of armaments. What the statement fails o do, however, is to make clear that this is the olicy which the British Government has consistently ollowed. It is also important to note the reservation hich Prof. F. J. Joliot-Curie made regarding the uggestion that war should be abolished. It reveals ow far we are still from convincing those on the astern side of the Iron Curtain that nuclear war nvolves universal destruction.

The problem which this division involves is not airly faced by Lord Russell and his co-signatories; hough if all the leading Governments could be rought to subscribe to the declaration only good ould result. None the less, the educational value of he statement is important and that can equally be said of the "Atoms for Peace" issue of *The Nation* and of a pamphlet "Atoms for Peace—not War" (published by Science for Peace, 16 Ulster Place, London, W.C.1. Pp. 31. 1*s*.) prepared by a group of scientists who believe that the threat of nuclear warfare can be removed. The latter pamphlet, to which Prof. C. F. Powell contributed a foreword, gives a brief review of the present situation in regard to the peaceful use of nuclear energy and of the discussions on abolition of nuclear weapons before summarizing the extent of agreement on international control. This account, however, is a little biased against the United States, and the suggestion that insistence on international ownership is the real obstacle, rather than the objection of the U.S.S.R. to a system of inspection and refusal to accept any sacrifice of national sovereignty, is unrealistic. The treatment of President Eisenhower's original "Atoms for Peace" proposal of December 8, 1953, is likewise ungenerous; but with those reservations the pamphlet indicates clearly the stage which has been reached in negotiation and the really decisive changes since the first proposals for the control of nuclear energy were made in 1946.

Those changes are the disappearance of the monopoly of nuclear weapons by the United States; the development of thermonuclear weapons by both the United States and the U.S.S.R.; the extensive development of means of delivering nuclear weapons using unpiloted rockets and the availability of such weapons to ground forces; and above all the devising of a 'breeding' process for atomic piles which has made development of large-scale nuclear power economic. The "Atoms for Peace" issue of *The Nation* is concerned more especially with these latter implications, and includes in particular an article by J. G. Beckerley, director of classification of the U.S. Atomic Energy Commission for five years, on the importance of limiting secrecy requirements to the minimum.

Scientists can probably best contribute to the education of the community as to the implications of nuclear weapons and the sacrifices or restraints on national sovereignty that are involved by articles such as that on the hydrogen–uranium bomb contributed by Prof. J. Rotblat to the *Bulletin of the Atomic Scientists* last May, or by Prof. M. Westergaard on "Man's Responsibility to his Genetic Heritage" in the June issue of *Impact of Science on Society*, rather than by such statements as that which Lord Russell has sponsored, or the Nobel Prize winners' appeal already referred to. Something beyond technical papers will be required before we can, as Sir Richard Livingstone has said, master atomic energy, and see that civilization is enriched and not cheapened by the indiscriminate gifts of technology, while the most difficult problems, economic, social, political and moral, are pressing for solution.

None the less, the contribution of science must be primarily factual, though imaginatively alive to the human social issues and keenly aware of the experience of the past gained not only in the United Nations but in the League of Nations and earlier.

Indeed, unless injudicious and premature attempts to force a system of world government, through which alone effective control of nuclear energy could ultimately be achieved, wreck the United Nations, that organization may well play a larger part in international affairs in its second than in its first decade. Apart from its impact on military science, the development of nuclear power for peaceful purposes is likely to demand and encourage co-operation and goodwill between the nations, and thus to prepare the way for a workable system of world-wide inspection and enforcement of nuclear disarmament. Any such system will be virtually impossible except under the auspices of the United Nations, simply for the technical reasons that methods for detecting radiation must be applied all over the world, and that advances in nuclear weapons will ultimately enable the smaller States also to possess them.

Meanwhile, scientists should be considering what further constructive part they can play in the education of world opinion as to the conditions under which the world can enjoy the full benefits of nuclear power, and the imperative necessity for fresh thinking about national sovereignty and international relations in this age of technology. Apart from making clear the price which has to be paid and the discipline and restraint demanded, there are many technical problems to which they must make the decisive contribution. Some of these problems are to be discussed at Geneva in the forthcoming Conference on the Peaceful Uses of Atomic Energy. There are many others, some of which have political aspects in which the scientific or technical contribution is equally decisive. While the preparation of world opinion for the sacrifice of national sovereignty proceeds, constructive thought is needed as to the details of an effective inspection system, for example, which would provide a practical alarm, without seriously hampering the conduct of internal affairs or invoking large surrender of sovereignty. Clear thought as to the essentials which should be known might well enable a small group of inspectors, at key points, to provide the surveillance of major production activities which would provide ample warning of mobilization, for example.

The contribution of science to world peace and the utilization of nuclear energy should be essentially practical. Apart from the task of education and of giving clear warning of the dangers attendant on abuse of the powers which are now placed in man's hands, it should above all be mindful of the conditions upon which the advance of science itself depends. In proportion as full freedom of interchange of knowledge across frontiers is re-established and science regains its international position, the risk of misunderstanding and abuse will diminish. A first duty of every scientist, and the most important contribution he can render to the cause of peace, is to take up the challenge which Sir Henry Dale threw down at the anniversary meeting of the Royal Society when the United Nations was but a few months old.

# ORIGINS OF THE TORSION BALANCE

**Roland Eötvös**

Gesammelte Arbeiten. Herausgegeben von P. Selén
(Im Auftrage der Ungarischen Akademie der Wisse
schaften.) Pp. lxxx+384. (Budapest: Akadémi
Kiado, 1953.) n.p.

THIS volume contains eleven of the princip papers of Baron Roland Eötvös (1848–191 The reputation of Eötvös as a physicist rests on tw really original ideas worked out over a period thirty years with great skill and thoroughness. Th first idea concerns the forces acting on a torsio balance. Eötvös realized that even when no outsi couple was deliberately applied, the variation in th direction of gravity from one end of a suspende beam to the other would produce a couple, and th this couple could be detected and measured if th whole instrument, including the torsion head and th case, were turned into several azimuths in successio and the position of the beam relative to the ca noted in each. The couples depend on the spa gradients of the components of the force of gravit of which only five are independent. Eötvös showe that four of these quantities could be obtained fro the measurements and that these were equivalent t determining the rate of change of the force of gravit along a level surface, the difference of the tw principal curvatures of the level surface and th directions of the principal curvatures. All this i worked out in his papers with the greatest completeness.

Having demonstrated that the torsion balanc would measure the gradients of gravity, he develope a portable instrument and applied it to geologica problems, in particular to the search for oil-bearin structures in Hungary. After the death of Eötvös the instrument was widely used in the United State and elsewhere; but from about 1937 its use rapidl declined in favour of the gravimeter, partly becaus of the much greater speed of operation of the latte and partly because of the lesser disturbance which i suffers from very local irregularities in density. It i possible that the present neglect of the instrumen is a passing phase and that, if the speed of operatio were increased by the use of electronic techniques, i might again find applications.

The second original idea of Eötvös was that th torsion balance could give a very precise verificatio of the constancy of the ratio of gravitational t inertial mass. His method depends on the 'force o gravity', as observed on the earth, being compounde of a part due to the attraction of the earth, and a part due to rotation. The former depends on gravitational mass, the latter on inertial. If the ratio i not the same for the masses at the two ends of th beam of a torsion balance, the beam will experienc a couple. The extreme sensitivity of the balanc enables a limit of about one part in $10^8$ to be set t the variation of the ratio from one substance t another.

These are the main themes of the work of Eötvös, though in reading the papers one finds many othe beautiful things; for example, a demonstration tha a sheet of lead 5 cm. thick does not absorb the forc of gravity by more than two parts in $10^{11}$, and th discovery that the rate of change with temperature of the product of the surface tension of a liquid and two-thirds power of its molecular volume is ghly the same for all liquids.

Ötvös was clearly a man of great ability and rgy, whose work has been too little known. stein, for example, remarks that when he first ught about the equivalence of gravity and leration he knew of the experiments of Newton Bessel on gravitational and inertial mass, but of those of Eötvös. It is to be hoped that the lication of these papers will make his work more ely known.

he book includes an interesting life of Eötvös by l Selényi. The delicate task of writing a foreword ving a suitable idealogical lesson from the fact the greatest Hungarian physicist was a baron been undertaken by K. Novobátzky.

# TREATISE ON INORGANIC CHEMISTRY

## mprehensive Inorganic Chemistry

ited by Prof. M. Cannon Sneed, Prof. J. Lewis ynard and Prof. Robert C. Brasted. Vol. 2: pper, Silver and Gold. By J. W. Laist; pp. x+ ; 35s. net. Vol. 3: The Halogens. By Prof. bert C. Brasted; pp. x+250; 35s. net. New York: D. Van Nostrand Company, Inc.; ndon: Macmillan and Co., Ltd., 1954.)

HE editors of this series of volumes on inorganic chemistry state that their aim is to emphasize emical properties and relationships and their erpretation in terms of theoretical concepts". This vides us with a canon of judgment. It is the ge and depth of such interpretations that dis-guish the inorganic chemistry of to-day from that even a quarter of a century ago. Valency theory, rmodynamics and other disciplines help us to est what used to be a great mass of unrelated ts. How far, we are entitled to ask, do these two umes, the second and third in the series, assist digestions ?

ol. 2, on copper, silver and gold, commences with useful table of the physical properties of the ments in question, followed by a brief intro-tion in which electronic structures, valencies, ., are discussed, and the stable and radioactive opes are tabulated. It then deals with each up $IB$ element in turn. Nearly half the pages concerned with the extraction metallurgy and h the alloys of the elements—a somewhat high portion. These sections, however, are quite well e, though one wishes that the treatment was less ely descriptive and more physico-chemical; there , too, inaccuracies in the section on the concen-tion of copper ores.

he remainder of the volume consists of a com-ation of facts about the chief compounds. It tainly does not go very far along the road of oretical interpretation, and though accurate ugh, it is distinctly haphazard. For example, the ts of formation of $CuF_2$, $Ag_2S$ and $AgF_2$ will be nd, but not those of any other compound, let ne any systematic discussion of the thermo-mistry. Again, the radius of the cupric ion does seem to be quoted anywhere, though that of the rous ion is; yet ionic sizes are fundamental to understanding both of crystal structure and of nplexes in solution. In short, although this volume contains much quite recent information, it is disappointingly old-fashioned in outlook.

After an introduction like that of Vol. 2, Vol. 3 proceeds first to the elementary halogens, including astatine; then in turn to the hydrohalides; the oxycompounds of the halogens; positive halogens, interhalogens and polyhalide anionic complexes; and finally to the pseudohalogens, such as cyanogen. It is more successful than Vol. 2 in carrying out the editors' programme of "interpretation in terms of theoretical concepts", and the choice of data seems more systematic. The much larger number of tables is a sign of this. There is good coverage, too, of the interesting new features of halogen chemistry that have been brought to light in recent years, such as the existence of positive halogen ions in solution and the solvent properties of bromine trifluoride. Technological developments—for example, in the handling of fluorine—are well described, though mention should have been made of the fact that anhydrous fluorine can be handled in glass apparatus.

The volume is unfortunately not free from blemishes. For example, it is a little sad to find the following sentences about hydrochloric acid in a modern text-book. "The equivalent conductance of a 0·001 $N$ solution is 377 and is 300·5 for a 1·0 $N$ solution (at 18°C.). This variation represents a change in apparent ionization from 99 to about 79 per cent". The word "apparent" may justify the letter of this statement; but in spirit it is pre-Debye–Hückel.

Nevertheless, Vol. 3 is an attractive one on the whole, and, like Vol. 2, it is well produced and remarkably free from printing errors.

# FUNDAMENTALS OF PHYSICAL METALLURGY

## Theoretical Structural Metallurgy

By Prof. A. H. Cottrell. Second edition. Pp. viii+251. (London: Edward Arnold (Publishers), Ltd., 1955.) 25s. net.

DURING the seven years that have passed since the appearance of the first edition of Prof. A. H. Cottrell's book, activity in the field of physical metallurgy has been considerable. The greatest progress has been in the study of the structural defects occurring in solids, such as grain and twin boundaries, vacant lattice sites, and dislocations, and the effect of these defects on diffusion and deformation. Important work has also appeared dealing, for example, with theories of metallic cohesion, the distribution of electrons in alloys, ferromagnetism, and the electronic structure of transition metals. In order to accommodate much of this material in a book of approximately the same length, Prof. Cottrell has rewritten the entire text, and has included an extra chapter. Naturally, some of the original has had to be condensed or rearranged, but this has been accomplished without loss of clarity, and is offset by an increase in the number of illustrations from 96 to 132.

In the first five chapters, which lead from the structure of the atom, through interatomic forces, to the zone theory, increased emphasis has been placed on quantum mechanics in order that the band structure of metals might be more fully understood. Since these chapters lead logically to the applications of the electron theory in Chapter 6, I feel that much of the chapter on metallic crystals, especially the nature and surface tension of grain boundaries, might well have been placed later. Chapter 6 includes superconductivity, Zener's ideas of the exchange interaction in ferromagnetism, and a more lengthy discussion of domain structures and of cohesion.

The following five chapters, which range from equilibrium and the rate of approach to equilibrium, to the equilibrium diagram, are notable for an extended treatment of the equilibrium concentration of vacancies and of the structure of liquid metals. Here also are included the Laves phases, the work of Raynor on aluminium and the transition metals, a much-enlarged section on interstitial phases, and a brief mention of Friedel's work on the bound states existing in copper, silver and gold-base alloys.

Considerable effort is being devoted at the present time to studies of diffusion in metals and alloys, being aimed especially at the mechanism of the process and the effects of grain boundaries, dislocations and chemical inhomogeneities. An understanding of the process of nucleation and growth has also been sought. A survey of this work is contained in the relevant sections.

Prof. Cottrell's eminence in the field of deformation makes the extra chapter, which is entitled "Shear Processes in Metal Crystals", most valuable. The types of diffusionless changes occurring by shear processes—such as slip, deformation twinning and the martensitic-type transformation—are described, together with the mechanism of simple shear. This leads on naturally to dislocations, to the types and properties of dislocations, spiral structures, dislocation networks, and to the Frank–Read source.

The general construction of the book remains much the same as the first edition, and the price has increased by only four shillings. It contains references up to 1954. As a work dealing with the fundamentals of physical metallurgy it can only be described as excellent, and may be recommended without qualification to all students of metallurgy.

J. A. CATTERALL

# RADIOBIOLOGY

## Fundamentals of Radiobiology

By Prof. Z. M. Bacq and Peter Alexander. Pp. xii + 389 + 14 plates. (London: Butterworths Scientific Publications, 1955.) 40*s*. net.

RADIOBIOLOGY is a mixed marriage of biological and physical sciences. The offspring of this union—radiobiologists—tend to suffer with psychological complexes which arise from a difficult upbringing. Formally trained in one discipline, they usually acquire proficiency in the other by apprenticeship. They feel that this latter method seldom gives them that mastery of the fundamentals of the science which is obtained from sitting at the feet of the professor.

In "Fundamentals of Radiobiology", Prof. Z. M. Bacq, a pharmacologist representing the biological sciences, and Dr. P. Alexander, a physical chemist, have combined to produce a book which will be best appreciated by the harassed radiobiologist or aspiring radiobiologist with the psychological complex.

From both the physical and biological aspects the book is written in a clear, convincing manner. Generally accepted facts are lucidly stated, which gives the student a feeling of confidence. Theories are expounded, due weight being given to the p and cons. The authors, having done this, usu sum up and set forth their own conclusions. T will please those who search for dogma, but n antagonize the esoteric who regard the theories still *sub judice*.

Broadly speaking, there are four large chapter on basic physics and physical chemistry—ei smaller chapters on various fundamental biolog aspects, morphological, physiological and biochemi and finally five small chapters on what may be ca applied radiobiology, including "Observations Human Beings". Each chapter has an extensive of references, "The 960 original papers quoted in bibliography represent a year's solid reading", there are author and subject indexes. The tex freely interspersed with tables and line diagra These admirable qualities are marred by a num of misprints.

# A SURVEY OF CURRENT PSYCHOLOGY

## l'Année Psychologique

Cinquante-Quatrième année, 1954. Fascicule 1; viii + 306; 1,000 francs. Fascicule 2; pp. vii 309–618; 1,200 francs. Directeurs: Henri Piér Alfred Fessard et Paul Fraisse. (Paris: Pres Universitaires de France, 1954–55.)

THE 1954 volumes of "l'Année Psychologiqu contain several substantial experimental pape notably the ones on chromatic sensibility of the fov (Galifret and Piéron), the structure of rhyt (Fraisse and Oléron) and the interpretation of t meaning of ambiguous sounds (Bresson). A p ticularly thorough investigation is one report by Scherrer, Barbizet and Oudot-le Hénaff on t organization of somesthetic sensibility, in which t authors establish the minimum intervals which perr successive cutaneous stimuli to be discriminated a discuss the various allied problems that arise determining differential thresholds.

Most of the papers deal with problems in psyc physiology, but some are concerned with 'pu psychological topics such as the relation betwe powers of abstraction and mental flexibility. The is also a paper on personality and æsthetic preferenc and a shorter one on applications to the fine arts. T briefer reports cover a wide range of subjects, inclu ing leadership, psychiatric tests, studies of defen mechanisms and the statistics of measurement scal

The critical reviews of current periodicals ensu that French readers are kept in touch with develo ments elsewhere—a valuable feature. Among t many reviews there is one by Henri Piéron, t senior editor of the volumes, of a recently publish American work in which he remarks that the auth "appears systematically to avoid all citation authors in the French language . . . and, even European authors in general". Piéron adds: ' seems that one seeks nowadays to give to Americ students the impression that America alone co tributes to the development of science, an attitu symmetrical to that of the U.S.S.R.". All in "l'Année Psychologique" easily ranks among the b publications of its kind, both in quality and ran in contemporary psychological literature.

JOHN COHEN

# NEW HIGH-SPEED ELECTRONIC TACHISTOSCOPE

By Prof. GEORGE HUMPHREY, P. G. M. DAWE and BERNARD MANDELL
Institute of Experimental Psychology, University of Oxford

AN apparatus has been devised by us for exposing two visual fields for very short time-intervals ith control of the interval between them. This ticle is concerned not only with the description of is apparatus but also with the visual problems volved in this kind of work and with an outline of he preliminary experimental results.

## Apparatus

The apparatus makes use of two banks of short-ecay phosphor fluorescent tubes. There are four W. tubes in a bank, and each bank illuminates a isual field which is 6 in. square. These two fields re viewed from the same window by using the onventional half-silvered mirror technique for the irect transmission of one field, and the reflexion of he other, into the observer's eyes. Fig. 1 shows a lan of the instrument.

The fluorescent tubes are operated by d.c., with he current through each tube regulated by a hard alve. This is switched on and off by applying negative bias to the control grid which is derived om an Eccles–Jordan type of electronic switch. his switch is operated by short pulses, of less than ne microsecond in width, and is d.c. coupled to the ontrol valves so that the transition from on to off vice versa is accomplished in less than a micro-cond. The pulses for operating the electronic witches (for there are two, that is, one for each bank f tubes) are derived from electronic timing circuits perating on the flip-flop principle and embodying sistance capacitance combinations to give the ecessary time-delays. The timing circuits are upled together to give the desired sequence of witching on the closing of a trigger button, which initiates the first timing circuit. The coupling is arranged to cause lamps 1 to come on first, followed by a dark-interval, and then lamps 2. The exposure time of both sets of fluorescent tubes may be continuously varied between 200 μsec. and 0·625 sec. by a stepped switch and potentiometer. The limiting factor at the short exposures is most probably the resonance radiation decay-time of the mercury atom. At these very short exposures the light output is not particularly rectangular; but at an exposure of 1 msec. upwards fairly rectangular light pulses can be obtained. This is shown in Fig. 2a, which is an oscillogram of two 1-msec. light pulses separated by an interval of 1¼ msec. The dark-interval between the pulses is variable over the range 0–0·625 sec., although, as shown in Fig. 2b (for 200-μsec. light pulses with zero dark-interval), the light pulses will overlap at zero dark-interval due to the decay and build-up times of the radiation. The light pulses were observed by using caesium–antimony vacuum photocells connected by short low-capacity leads to the cathode-ray oscilloscope. Millisecond timing-pulses derived from a 1,000 c./s. square wave are shown superimposed on the Y1 beam of the oscilloscope for the purposes of measurement.

The light spectrum of the fluorescent tube is continuous, being that of the magnesium tungstate phosphor, together with the addition of the principal visual lines at 4047 and 5461 A. from the excitation

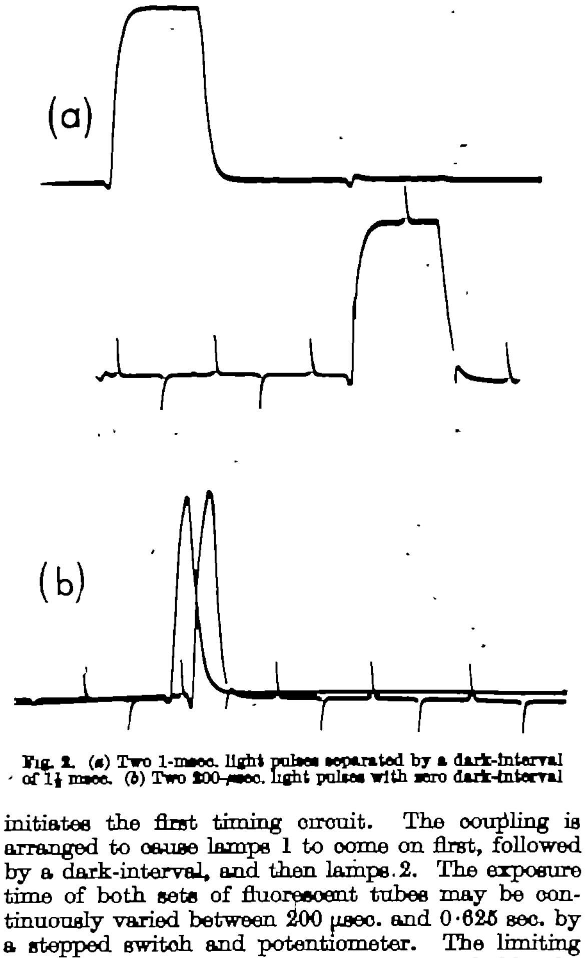

Fig. 2. (*a*) Two 1-msec. light pulses separated by a dark-interval of 1¼ msec. (*b*) Two 200-μsec. light pulses with zero dark-interval

of the mercury atom. Compared with daylight, the spectrum from the tube is somewhat deficient in red light. However, it is still possible to distinguish adequately between colours even at the shortest exposure times. The actual chromaticity co-ordinates of the lamp are given as $x = 0{\cdot}230$ and $y = 0{\cdot}290$.

The intensity of light from each bank of tubes is controlled by means of a variable resistor connected in the cathode circuits of the group of power valves feeding each bank of tubes. In this way the maximum current, and therefore the brightness, of the tubes can be varied over a range of approximately 2/1. The tachistoscope may, of course, be operated repetitively from an external pulse generator, and for the purpose of visual monitoring of the light pulses it proved convenient to do this at a repetition-rate of 10 per sec., the light outputs being displayed as an oscillogram.

## Visual Problems

In designing the apparatus, completely simultaneous exposure of all parts of the field was felt to be important, for modern neurophysiological considerations seem to leave open the possibility that sequential exposure may affect the manner in which an object is perceived[1-3]. The point was apparently first raised by Erdmann, more than sixty years ago, with reference to the tachistoscopes of the time, which, with the exception of those using an electric spark where the duration could not feasibly be varied, were either of the rotating wheel or other kind of moving-shutter type. In these the 'scanning' effect was said to be clearly visible, for longer exposures at least. Erdmann stated in a seminar that simultaneous exposure of the whole field with a variable exposure time was desirable but impossible. Dodge (personal communication, 1924) thought he had solved the problem with his mirror tachistoscope, the optical part of which has now become standard; but since he used a swinging pendulum as a shutter, he had really not done so.

It will be realized that in rapid exposures the phenomenal effect may be, and often is, one of complete simultaneity, when in fact the field has been scanned, either by part of a sector of a circle (Schumann) or by excursion of a rectangular slot in a moving shutter. On looking, for example, at a landscape, painted on a card, through an instrument of the circular, rotary, type in our laboratory, with an exposure of 1 msec., one sees the whole landscape appear as a single view, with no suggestion of the piecemeal and successive presentation which is actually occurring. Since the aperture was here smaller than the card, the total picture was never projected at one time on the retina. The effect is almost certainly due to some form of organic integration as the result of which a single picture is perceived when different retinal areas have been successively stimulated. This kind of process is, of course, not uncommon, the ordinary cinematographic picture being an obvious example. All this has been the subject of controversy, one side maintaining that, so long as the whole object appears simultaneously, the method of exposure is irrelevant. This conclusion is not justified *a priori* since, however clear and unitary the perceived object may be, the serial exposure and other features of this method of presentation may introduce phenomenal distortions ordinarily not noticeable, and which may prove important in accurate work. Whether this is so can only be discovered by experimental comparison of identical
objects as seen by the two types of apparatus, a
this is now being done. Similar considerations app
to the light pulse, which should ideally be of re
angular form. Herein lies the chief objection to t
ingenious instrument of Grindley, which focuses t
shutter on the lens of the eye and the object on t
retina, giving indeed a view of the whole obje
without 'scanning' but with a light pulse far fro
rectangular for its time base[4]. An adaptation of t
principle might, however, give good results at tim
shorter than are possible with Grindley's model.

It is further noteworthy that our problem is mu
more difficult than that of producing a short flash
an area of the retina, as for example in the expe
ments of Brindley and Crozier using a revolvi
mirror and a polarizable crystal, respectively[5,6].
any tachistoscope a total field must be illuminat
so that the effect of short exposure on complex pe
ceptual patterns can be observed.

Apart from the manner of field-illumination of o
instrument, which to our knowledge is superior
any yet built in its combination of simultaneit
very short and continuously variable exposur
together with practically rectangular light puls
from 1 msec. to 0·625 sec., an important new featu
is the timed dark-interval, between the two exposur
This enables closely timed work to be done on t
effect of a second exposure occurring after a variab
period; it is hoped, for example, that it will thro
light on what has been called 'metacontrast' (n
hibitory effect of post exposure[3]), Dodge's 'clearing-u
process'[7] and the possible effect of eye movement
subsequent vision.

## Preliminary Experimental Results

Taking as a starting-point the 'clearing-up proces
experiments of Dodge[7], an investigation was unde
taken into the conditions for clear vision of a patter
with very short exposures of consecutive fields. Th
experimental situation involved dark pre-exposu
and post-exposure fields, two illuminated fiel
(called here 'first field' and 'second field') and a dar
interval between them.

The luminance of both fields, the areas of whic
were 6 in. × 6 in., was equal and constant (70 mill
lamberts). The first white field, on which a 2-i
black cross was inscribed in two circles 1 in. and 2 i
diameter, with the line 0·1 in. thick, was followed
a second clear field of varying duration. It w
established that the perception of the pattern f
exposures from 0·2 to approximately 6 msec. coul
be totally prevented by a second field of somewh
longer duration, and that for exposures from appro
imately 6 to 30–35 msec. this period was of short
duration than the first field. (These are results for o
subject—forty years old—over the whole range
experiments. The individual differences betwee
subjects are considerable.) A pattern exposed f
more than 40 msec. was always, at least in par
perceptible, although with long second fields t
subjects saw it as a luminous cross, often followe
by a positive after-image. A disturbance in visibilit
of the pattern over all the range of exposure w
experienced when using second fields of short
duration than those producing total inhibition.

Taking into consideration that the pattern fie
was easily perceptible when exposed without t
second field, that the luminance of both fields w
equal, and the time relations, it is not convenient
describe the disturbance in terms of glare.

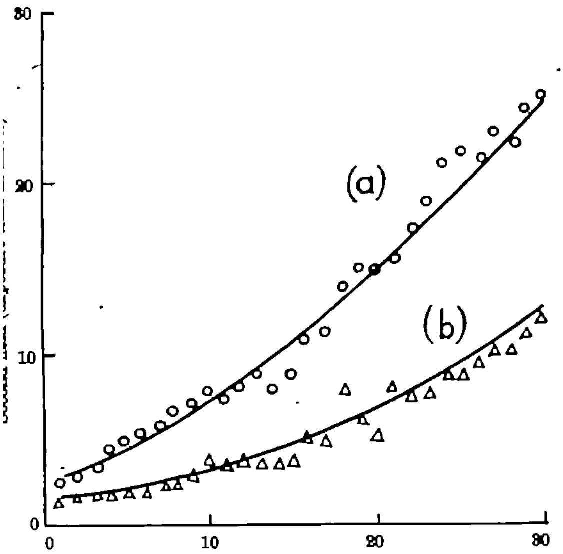

Fig. 3. Duration of a second field preventing or disturbing the visibility of the pattern in the first field: (*a*) no visibility; (*b*) bad visibility

The inhibitory or disturbing influence of the second eld could be prevented by interposing a short dark-nterval between the two fields. An interval of 5 msec. and more was necessary when a field of uration of 0·2 msec. was followed by a second field f duration more than 20 msec. For first fields of onger duration the dark-interval necessary for pereption of the pattern was considerably shorter; for xposures more than 15 msec. a dark-interval of 0 msec. was usually adequate. The experimental esults were cross-checked by eeping the exposure time of the rst field and the dark-interval onstant and increasing the durtion of the second field until he pattern was no longer visible.

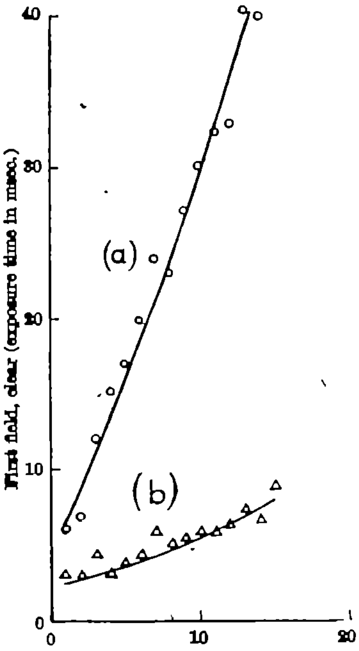
The reverse situation occurred hen a clear first field was folowed by a second field with a attern. A clear first field of -4½ msec. duration produced a isturbance in perception of a attern exposed for 1–5 msec., nd one of 4½–7 msec. prevented lear vision in pattern exposures p to 14–15 msec. A pattern xposed for 15 msec. and more ould not be rendered totally nvisible to the subject by a first lear field of the same luminance, hatever its duration.

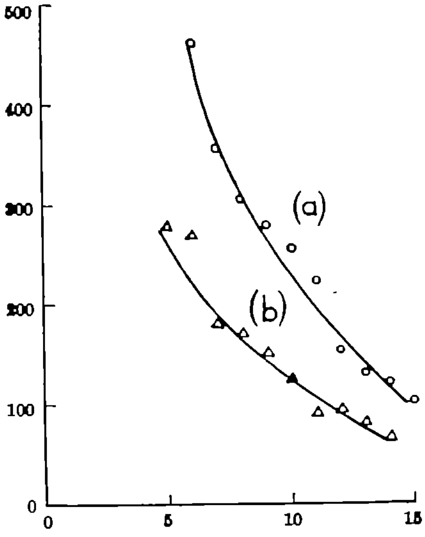
When the second field with he pattern was exposed for nore than 6 msec. (but less han 15 msec.) and the duraion of the first field was coniderably increased (permitting ome degree of adaptation), the ubject reported a reappearnce of the pattern. For exmple, with a pattern second ield of 6 msec. he reported t 4 msec. duration of the rst field a disturbance of vision, at 21 msec. a total disappearance of the pattern, at 240 msec. an appearance of a white cross on grey background, at 270 msec. the cross became blackish, and at 460 msec. the whole pattern was well cleared up. A pattern second field of 15 msec. duration was partly invisible with a 5 msec. clear first field. The biggest disturbance of vision was at 55 msec., but there was no total inhibition. At 73 msec. the subject reported improvement in vision, and at 103 msec. he reported a sharp, clear pattern. During the reappearance range he reported the arms of the cross 'coming back' earlier than the circles, and seeming very long and protruding beyond the circles.

As in the first experiment, a short dark-interval facilitated the perception of the pattern otherwise invisible. With very short first fields the subject reported the pattern as 'being there from the very beginning'. With long exposure of the first fields the pattern 'jumps' into the clear field.

The dark-interval was not always perceptible as an interval, and only in very few cases as 'dark'. There was a range of complete fusion of the first field and second field, a range of flicker and impression of doubleness with some apparent movement of the pattern, and a range of definite separation. The most important factor seems to be the duration of the first field in relation to the duration of the interval. The problem was investigated by Dunlap[8]; but his investigation technique was orientated towards 'singleness–doubleness' impression and towards perception of a dark field between moving illuminated ones, and not towards perception of interval, so that the problem is still with us.

Another problem arising from these experiments is that of the persistence of vision after stimulation has ceased. This can be expressed in terms of a dark-





Second field, with pattern (exposure time in msec.)

Fig. 4

Fig. 4. Duration of a clear first field preventing or disturbing the visibility of a pattern in the second field: (*a*) no visibility; (*b*) bad visibility

Fig. 5. Visibility of the pattern in the second field with long exposures of the first field (50–500 msec.): (*a*) all pattern clear; (*b*) part pattern discernible

interval which it survives to fuse with the second field (a cross on the first field inscribed in the circle on the second field). This is not claimed to be a time measurement, as the second field is itself an experimental variable influencing the first field.

Experiments upon metacontrast indicate that an explanation in terms of contour building process (similar to Werner's interpretation of his 1935 contour experiments[9]) cannot account for all the phenomena, since inhibition occurs with irregular and incongruent contours. Both tachistoscopic experiments and experiments with intermittent stimulation point to the importance of retinal distances, although Alpern's[10] statements are not fully acceptable.

The building of the apparatus and the conduct of the experiments were under the general supervision of Prof. G. Humphrey; the tachistoscope was designed and built by P. G. M. Dawe, and the great majority of the experiments performed by B. Mandell. The apparatus and research were carried out by the aid of grants from the Medical Research Council and the Watts Bequest. Acknowledgment is also made to the British Thomson-Houston Co., Ltd., Rugby, which manufactured the fluorescent tubes for this apparatus.

# MAGNETO-HYDRODYNAMICS

A DISCUSSION on magneto-hydrodynamics, organized by Sir Edward Bullard, was held in the rooms of the Royal Society on May 5. The proceedings were opened by Sir David Brunt, who took the chair for part of the discussion; he welcomed particularly the visitors from overseas, some of whom came from far afield. In his introduction Sir Edward Bullard said that the subject, which is concerned with the motion of a conducting fluid in a magnetic field, is not entirely new; but it was Prof. H. Alfvén, of Stockholm, who had rescued it from obscurity. The electromagnetic effects associated with such a motion are more conspicuous on a large scale, and the principal applications so far made are to astrophysical problems such as the theory of the sunspot field, the general solar magnetic field and stellar magnetic fields. There are also some applications in engineering, especially to pumps and flowmeters.

The subject is one which is understood in principle in so far as the relevant equations are known, being in fact the union of Maxwell's equations and the equations of motion and continuity of hydrodynamics. Sir Edward discussed at some length the terms in these equations which can be neglected in astrophysical problems. The solution of the equations is, however, a matter of real difficulty. Most of the solutions so far obtained have been derived from linearized equations, and he mentioned some examples of such solutions.

The next speaker, Prof. Alfvén, said that mathematical methods have been largely used for exploring the subject of magneto-hydrodynamics since it inception; but he pointed out that it is essential t explore the subject by means of experiments also i so far as certain aspects of the subject, as in the cas of turbulence, cannot be ascertained by mathematica methods alone. He considered such experimenta methods to be essential for a proper understanding o magneto-hydrodynamics. For excitation of mag neto-hydrodynamic waves in the laboratory, it i essential that the field-strength $B$, the linear dimen sion of the apparatus $l$, the conductivity and th density of the liquid $\sigma$ and $\rho$, respectively, shoul satisfy the inequality

$$Bl\sigma/\sqrt{\rho} \gg 1.$$

In the laboratory, we can attain fields of strength o the order of 10,000 gauss, and with such field magneto-hydrodynamic waves can be excited i mercury and sodium. On the cosmical scale, $l$ is ver large, and the above condition is amply satisfied.

Prof. Alfvén then went on to discuss the nature o currents occurring in magneto-hydrodynamic effect in the ionosphere and solar atmosphere, and he wa of the opinion that we have little evidence of current extending over a large volume; these, he thought tend rather to occur as filaments, and in support o this conclusion he quoted the auroral zone and the equatorial electrojects as examples. This effect i thought to be important in so far as it suggests the possibility that currents extending over large volume are unstable.

Dr. B. Lehnert next described some beautifu experiments on magneto-hydrodynamics which he has lately carried out in Stockholm. In this, a shallow cylindrical bath contains mercury in which a brass ring is inserted, capable of rotating about the vertical axis of the cylinder. There is a fixed horizontal circular disk within the ring, and a fixed annular disk outside it, both concentric with the disk resting half-way up the vessel. Dr. Lehnert showed that when the ring is rotated in a strong magnetic field the mercury over the ring is carried round as a rigid body, the outside fluid remaining at rest. Sir Edward Bullard interpreted this as an example of the theorem that, in a highly conducting liquid moving in a magnetic field, the magnetic lines of force are frozen in the fluid and tend to be carried by the fluid.

In the discussion that followed, Prof. S. Chandrasekhar showed some slides of some experiments made in the University of Chicago illustrating the inhibition of convection in mercury in the presence of a magnetic field. Prof. T. G. Cowling, referring to Alfvén's statement that cosmical currents tend to occur as filaments, said that he doubted the validity of this statement and that a filament current is more characteristic of an electrical discharge in gases.

Dr. D. Layzer next gave an account of a paper by himself, Dr. D. Menzel and Dr. M. Krook on torsional oscillations and solar magnetic fields. Dr. Layzer began by recalling the suggestion made by Cowling and Bullard that sunspot magnetic fields may be the result of a subsolar toroidal field which is convected to the surface. He suggested that, if the law of isorotation were violated at some initial instant, an alternating toroidal field would be produced by torsional oscillations of shells of magnetic lines of force, the sign of the field changing every half-cycle. Because of the low values of the kinematic and electromagnetic viscosities, such an oscillation could have existed throughout the past lifetime of the sun.

Dr. Layzer next considered how the submerged roidal field is brought to the surface. The growth a toroidal field at the base of the hydrogen convec- on zone gives rise to a hydrodynamic instability alogous to the instability of superposed fluids in a avitational field when the upper fluid is heavier an the lower fluid. The tension of the magnetic les of force plays a part analogous to that of surface nsion, so that if one supposes that there is a sharp terface between the region containing a magnetic ld and the overlying region in which no magnetic ld is present, ripples of small amplitudes will tend grow. Dr. Layzer suggested that this instability, ther than convection, is effective in convecting the bsolar toroidal field to the surface. The formation d subsequent dissipation of sunspot fields would aw energy mainly from the convection zone rather an from the primary oscillation. The equations verning the oscillations turn out to be linear in a st approximation, even if the amplitude of the cillation is large. Hence, for a given magnetic ell the period is nearly independent of the ampli- de. This point is a vital one in the theory which ntemplates large-amplitude oscillations rather than all vibrations about an equilibrium state.

In the discussion that followed, Prof. Cowling ointed out that Walén has shown that a reasonable rface field would be produced by a variation in me of 1–2 per cent in mean angular velocity. ichardson's measurements at the surface do not ow this. Hence, a substantially higher surface eld-strength would be required.

Prof. V. C. A. Ferraro next discussed the generation f magneto-hydrodynamic waves in rare ionized ases and its bearing on galactic magnetic fields. oubts have been expressed by several workers as to hether a rare ionized gas could behave as a perfect onductor on account of the very long free paths volved. Prof. Ferraro said that, if one neglects ollision altogether, magneto-hydrodynamic waves ay be excited in such a gas in the presence of a seed') magnetic field provided that the frequency f the waves is small compared with the gyro- agnetic frequencies of the charges. The phase elocity of the waves is the same as that found by lfvén; but the waves differ from magneto-hydro- ynamic waves in liquids in that they are circularly olarized. In order to excite the waves, the linear imensions of the gas must exceed the 'skin depth', hat is, the depth to which an external alternating eld would penetrate into the gas. As in the case f Alfvén waves, there is equipartition of mechanical nd magnetic energy independently of the magnitude f the 'seed' magnetic field. Thus, provided a eneral magnetic field exists in the galaxy, however mall, much larger fields may be generated, by mag- ification, as magneto-hydrodynamic waves through onvection or turbulence. But it is essential that he 'seed' field should have an 'external' origin, and his assumption is difficult to substantiate.

Prof. Cowling considered the problem of magneto- ydrodynamic oscillations of a rotating fluid globe nd, in particular, torsional oscillations. Steady otation can only hold for isorotation. Torsional scillations in the absence of rotation has been onsidered by Plumpton and Ferraro, who found a ontinuous spectrum for the normal modes of vibra- ions. This degeneracy might be removed by otation; but in this case, Prof. Cowling pointed out, he variable magnetic field associated with the field annot be purely azimuthal. On a rotating globe there must be, in addition to this field, a poloidal field also. Prof. Cowling referred to the equations of the problem and the boundary condition to be satisfied, and stated that these are sufficient to determine the solution. In the absence of rotation, the period of the oscillations is $2\pi/\sigma_0$, where

$$\sigma_0 = \frac{H}{a\sqrt{(4\pi\rho)}}$$

$H$ being the magnetic field, $\rho$ the density of the liquid and $a$ the radius of the star. If the angular velocity of the globe $\Omega$ is greater than $\sigma_0$, the Coriolis forces will greatly affect the period: in this case the magnetic forces are balanced by the Coriolis forces, and we get

$$2\Omega\sigma \sim \sigma_0^2$$

where $2\pi/\sigma$ is the period of the oscillation; this would therefore exceed $2\pi/\sigma_0$. In the case of the sun, one finds that the differential angular velocity is destroyed in a time of the order of $10^7$ years or more instead of 100 years. These results, however, do not apply to real stars, since the calculation is vitiated by the neglect of gravity. For, gravitational terms arise which largely prevent motion in meridian planes, and this means that the azimuthal Coriolis forces are no longer larger than the magnetic forces; thus, in spite of the fact that Coriolis forces are large, one can ignore them in considering torsional oscillation in actual stars. One may probably approximate to the periods of torsional oscillations using a form of Rayleigh's principle. In the discussion that followed, Prof. H. C. van de Hulst said that the solar cycle might well be a phenomenon too irregular to be classed as an oscillation.

Prof. Chandrasekhar opened the afternoon session with an account of an elementary theory of hydromagnetic turbulence which he has developed recently. He said that he has also developed a deductive theory along the lines of his recent theory of hydrodynamic turbulence; but there was no time to discuss it that afternoon. (It is understood that this will be published elsewhere.) The elementary part of the theory follows along the lines of Heisenberg's theory of ordinary isotropic turbulence. Prof. Chandrasekhar described in some detail the exchange of energy between the velocity field and the magnetic field; this, he showed, can be described in terms of an eddy resistivity and the spectrum of the random magnetic field, in a manner analogous to that of the inertial exchange of energy between the different Fourier components of the velocity field in terms of an eddy viscosity and the spectrum of the kinetic energy in Heisenberg's theory. The equations of stationary turbulence in this case lead to two essentially distinct solutions of the problem. Both solutions predict equipartition of kinetic and magnetic energy among the largest eddies present. For the smaller eddies, the ratio of the magnetic to the kinetic energy either tends to zero or to 2·6. Prof. Chandrasekhar then referred to the bearing of this theory on interstellar magnetic fields and especially the possibilities of distinguishing between Fermi's two pictures of galactic magnetic fields.

In the discussion that followed, Prof. van de Hulst asked whether, in Fermi's theory of the galactic magnetic field using gravitational arguments, the gravitational potential of the whole galaxy rather than that of a spiral arm should be considered. Furthermore, if the field is turbulent, can this be adopted as an explanation of starlight polarization? Dr. Layzer asked whether differential velocities are not likely to be more effective in getting higher magnetic fields; and finally Prof. H. Bondi asked whether the method adopted by Prof. Chandrasekhar is sensitive to deviations from isotropy. Sir Edward Bullard commented that equipartition of energy for large eddies does not exist in the earth's core; there the force driving the material has to be taken into account.

Dr. A. Banos began by recalling the fundamental notions in the theory of magneto-hydrodynamic waves originally given by Alfvén. He referred to the work of Walén and to the laboratory experiments of Lundquist and Lehnert, but he said that no complete account of fundamental equations has yet been given without making simplifying assumptions. A start has been made by Dr. Banos in a recent paper (*Phys. Rev.*, **97**, 1435; 1955), and his contribution amounted to an account of this paper, which is a systematic study of the problem. He showed how the equations of the problem, namely the Eulerian equation of hydrodynamics and the Maxwellian equations, can be reduced to one fundamental equation in the fluid velocity. Dr. Banos then considered the linearized form of this equation and its solution for the case of incompressible fluids, and compressible fluids (which gives rise to magneto-acoustics) for the case of plane and cylindrical waves.

The next speaker, Dr. W. Marshall, discussed the structure of magneto-hydrodynamic shocks. He first recalled the structure of an ordinary shock-wave, and then considered theoretically the detailed structure of an infinite plane shock moving with uniform velocity into a region of stationary ionized gas in the presence of a magnetic field perpendicular to the line of flow. When the 'penetration depth' is smaller than a mean free path (as in the case of high electrical conductivity), the field is very nearly proportional to the density, and the shock point has a width of the order of a few free paths. In the case of a conducting gas of low conductivity, if the permanent magnetic field is less than a certain critical value, depending on the strength of the shock, we have a sharp shock in which only the velocity and temperature change is preceded by a wider region in which the velocity, temperature and field change slowly. In this case, we have the surprising result that the field changes take place ahead of the shock. When the permanent magnetic field exceeds the critical value, it prevents the rapid changes in velocity and temperature, and no sharp shock occurs. All quantities change slowly in a wide region.

Dr. R. Hide spoke on the generation of waves in a heavy electrically conducting fluid of variable density in the presence of a magnetic field. Considering the stable case in which the density decreases vertically with height, Dr. Hide said that the fluid always tends to return periodically to its equilibrium state when viscosity is zero. In this case the motion gives rise to 'gravity' waves propagated horizontally. In the case of a viscous fluid, only modes of disturbance characterized by an infinite range of wave-lengths generate damped gravity waves, other modes decaying aperiodically. If the fluid is conducting and there is a magnetic field present, the gravity waves are modified by electromagnetic waves. The linearized equations for any variation of density and kinematic viscosity are solved by a variational principle for the case when the electrical conductivity is constant and the impressed magnetic field uniform.

In the case of a continuously stratified fluid of finite depth, Dr. Hide was only able to examine in detail the case of infinite conductivity. The properties the motions depended on two parameters $G$ and defined by

$$G = \frac{g\beta d^4}{\pi^4 \gamma^2}, \quad Q = \frac{\mu H_0^2 d^2}{\pi^2 \rho \nu^2}$$

where the density $\rho(z)$ is given by $\rho = \rho_1 \exp(-\beta z$ $H_0$ is the uniform magnetic field, $\nu$ the kinema viscosity, $d$ the depth of the liquid, $g$ the accelerati of gravity, and $\mu$ the magnetic permeability. If is the horizontal wave number of the motion, D Hide finds that waves can be generated within finite range of $k$ if $G > 27/16$ and $Q < 1$, whereas wh $Q < 1/2$ and $G < 27/6$ all modes are aperiodical damped, so that no waves are generated.

Dr. J. A. Shercliff spoke on some engineerin applications of magneto-hydrodynamics. He sa that engineers are interested in magneto-hydrodyn mics chiefly on account of its use in electromagnet pumps and flowmeters for liquid metals in nucle power plants and elsewhere. The fluid motion pumps is complex and difficult to analyse; th flowmeter problem is simpler, however, especially turbulence is suppressed by the transverse magnet field. The sensitivity of a flowmeter depends on th form of the velocity profile, and this may be disturb by electromagnetic forces or upstream disturbance As the fluid moves across the transverse magnet field, currents are induced which affect the velocit profile and sensitivity.

Dr. Shercliff then considered the equations of th problem; these involve two parameters, th Reynolds number and a number depending on th magnetic field. If the transverse magnetic field is sufficient extent in the direction of flow, there is further distortion of the profile, and in a circul non-conducting tube the sensitivity falls by som 7 per cent if the velocity profile is fully distorted fro axial symmetry by electromagnetic forces. Th theoretical results obtained have been verified exper mentally. Dr. Shercliff also considered the effect orifices in the surface of the tube, and said that th sensitivity can be large or low or even negative various points of the surface of the tube.

The last speaker, Dr. W. B. Thompson, considere the acceleration of cosmic-ray particles by magnet hydrodynamic waves. Dr. Thompson first reviewe Fermi's theory of the origin of cosmic rays pu forward in 1949 and recalled that Fermi had derive the exponent in the energy law as the ratio of tw times—an acceleration time $t_1$ and a mean life energetic particles $t_2$. In this theory the particle gain energy through elastic collisions with a movin magnetized cloud of gas. In a form of the theor due to Morrison, Olbert and Rossi, $t_2$ represents th time needed for an energetic particle to diffuse out the galaxy, and the theory seems able to provide a explanation of most of the observed features of th part of the cosmic-ray flux of greatest energy However, on this theory $t_1$ is of the order of $10^8$ year which is at least an order of magnitude too larg This led Fermi to attempt a more efficient acceleratin mechanism.

Dr. Thompson then directed attention to a mech anism, so far overlooked, indicated by recent view on the galactic magnetic field. If one supposes, wit Chandrasekhar and Fermi, that there is a genera field of the order of $10^{-6}$ gauss in a spiral arm and Fermi's magnetized clouds are also present, thes might act as scattering centres enabling cosmic-ra particles to be accelerated to high energies by th lectric fields associated with the magneto-hydro-ynamic wave. On the basis of this mode, an pproximate calculation of the rate at which relativistic particles acquire energy leads to a time $t_1$ such that

$$\frac{1}{t_1} \sim \frac{1}{x}\frac{v}{c}\left(\frac{\delta H}{H}\right)^2$$

where $v$ is the velocity of the magneto-hydrodynamic wave of wave-length $\lambda$, and $\delta H$ is the amplitude of he wave. By taking $v$ to be of the order of 30 km./sec. the value adopted by Fermi), $\lambda$ of the order of 0 light-years, $\delta H/H \sim \frac{1}{4}$, one finds $t_1$ to be of the rder of $10^6$ years, a value small enough to give greement between astrophysical and cosmic-ray data.

V. C. A. FERRARO

# OBITUARIES

## Dr. C. S. Orwin

DEEP regret will be widely felt for the death of Charles Stuart Orwin at his home at Blewbury, Berkshire, which occurred on June 30. He was born at Warnham in Sussex in 1876 and was educated first at Dulwich College, then at Wye College, which he entered in 1895, its second year of establishment as an agricultural institution. He was fortunate both n his fellow students and in his teachers: the subject was new and the principal, A. D. Hall, had the gift of attracting an able body of enthusiastic pioneers. Orwin thoroughly absorbed the spirit of the place and throughout his life held it in great affection; in particular, he had great admiration for Hall, who in turn thought very highly of him.

Orwin early became interested in the organization and development of agriculture, and on leaving Wye n 1897 he worked with an estate agent in Tonbridge and then for a short time in the City of London; he returned to Wye in 1903 as lecturer in estate management. He did not, however, remain long. Mr. Christopher Turnor, who had inherited the family estates in Lincolnshire, wished to develop them on sound lines, and in 1906 he invited Orwin to take over the management; this he did with satisfaction to all concerned.

Meanwhile, A. D. Hall was insisting that agriculture as a technical subject could not be taught apart from quantitative knowledge about the various operations; he was surprised at the vague ideas on the subject of costs and times required that were held by the ordinary college lecturers. Orwin took up the subject with enthusiasm, developed systems of bookkeeping which farmers could use, and built up a body of carefully ascertained knowledge on farming operations and their results, on which a new subject, agricultural economics, could be built up. Hall by this time was the Permanent Development Commissioner and had established an Institute for Agricultural Economics at Oxford: Orwin was put n charge and, with the aid of a succession of able young colleagues, was able to produce a series of valuable reports, first on a county basis, afterwards on more general lines. He was appointed assessor to the Agricultural Tribunal set up in 1922 to study the agricultural crisis of those days, and its report, issued n 1924, for the drawing up of which he was largely responsible, is justly regarded as one of the best on the state of British agriculture.

He was much interested in the history of agriculture, and was fortunate in having an able helper in the gifted wife of his second marriage. Together they produced in 1939 "The Open Fields", based on a study of the system still surviving at Laxton; this is now the standard treatise on the subject. His other works included an account of John Knight's reclamations at Exmoor in the early nineteenth century, a subject in which interest has been renewed by Earl Fortescue's recent reclamations, and a very readable short "History of English Farming" (1949). He adopted Hall's revolutionary view that the Government should acquire all the agricultural land of the country and redistribute it in larger units; he dealt with this in "Speed the Plough". His method of investigation is well seen in "Country Planning, a Study of Rural Problems" (1944), the work of a team under his direction.

Orwin's wide knowledge, sound judgment and deep sympathy with the small farmer and the worker made him a very acceptable member of the Agricultural Wages Board and of numerous other committees of inquiry, while Balliol College very shrewdly secured his help by making him estates bursar. He had his share of honours: Oxford conferred upon him the degree of D.Litt., Balliol made him an honorary Fellow and Wye College also elected him to a fellowship; but he lives in the memory of those who knew him as a friend ever ready to help and who steadfastly maintained the best traditions of the English country gentleman.

E. JOHN RUSSELL

## Prof. F. J. Lewis

THE death of Francis John Lewis on May 24 at the age of eighty marks the passing of one of the very few links left with the grand old tradition of British botany led by Bower, Oliver, Gwynne-Vaughan and others. Unlike most of his contemporaries, however, Prof. Lewis spent most of his botanical career overseas.

He was born in London in 1875 and received his early training at the Imperial College of Science and Technology, London, and at the University of Liverpool, from which he received the degrees of M.Sc. in 1908 and D.Sc. in 1912. He was appointed demonstrator in the University of Liverpool and held this post until 1905 and then became lecturer in geographical botany until 1912. During that time he did a great deal towards establishing the branch of geographical botany in undergraduate courses. In 1912 he was appointed professor of botany in the University of Alberta, Edmonton, Canada. There he worked and developed that department for twenty-three years until he resigned in 1935.

Lewis was an exceptionally active man both physically and mentally, and this meant that he could scarcely be expected to live in retirement. So in 1935 he exchanged to a very different environment—that of Egypt, where he was appointed professor of botany in the Fouad I University of Cairo in succession to F. W. Oliver. His headquarters were for some years in the old Zafaraan Palace at Abassia. In spite of the hampering episodes of wartime in the Middle East, he developed a small laboratory on the Suez Road where he investigated the phenomena of dew formation in the desert and studied the permeability of leaf tissues. He also took a leading part in the transferring of the Botany Department to the fine new building at Giza. There he organized the spacious laboratories and built up an excellent staff of Egyptian botanists. From the new laboratories, the botanical staff were able to work in much closer co-operation with the Egyptian Ministry of Agriculture Laboratories, the Cotton Research Laboratories and others which were nearby.

Although Prof. Lewis retired from Cairo in 1946 when he was seventy-one years of age and returned to Great Britain, he was still as active as a man half his age. He therefore accepted for one year the appointment of visiting lecturer in plant physiology in the Royal Holloway College (University of London). His knowledge of physiology and ecology stood him in good stead, not only there, but also in other activities such as that of an advisory editor to the new edition of "Chambers's Encyclopædia".

In 1905 Lewis was awarded the Cuthbert Peel Fund of the Royal Geographical Society and in 191 he was awarded the Neill Gold Medal of the Roya Society of Edinburgh, of which he was a Fellow. H was also Fellow of the Royal Society of Canada an of the Linnean Society. His work in connexion wit "Chambers's Encyclopædia" instilled in him a enthusiasm for publications, with the result tha right up to the time of his death he took an activ part in forming a liaison between the publishing fir of Macmillan and Co., and British universitie visiting them all in turn.

# NEWS and VIEWS

## The Indian Botanic Garden : Dr. K. P. Biswas

Dr. K. P. Biswas retired on August 1 from his post as superintendent of the Indian Botanic Garden. He was appointed curator of the Herbarium of the Botanic Garden in 1927, and superintendent in 1938 when Mr. C. C. Calder retired. Dr. Biswas specialized in Algæ and systematic botany. He was granted study leave in Europe during 1937–38 and worked at Dr. F. E. Fritsch's laboratory at Queen Mary College, the Edinburgh Botanic Gardens and at the Herbarium of the Royal Botanic Gardens, Kew. During this time he was awarded the D.Sc. degree of the University of Edinburgh. He has published a number of papers in the *Records of the Botanical Survey of India*, of which he was the editor, and in several local and foreign journals—*Kew Bulletin*, *Hooker's Icones Plantarum*, etc. He has also published some important botanical treatises, among which is "Bharatiya Banaushadhi" in Bengali (3 vols.)—a joint publication for which he was awarded the Rabindra Memorial Prize in Science in 1951–52. A book on "Medicinal Plants of Sikkim Himalaya" is now passing through the press as a result of his detailed study of the Flora of Sikkim Himalaya. Improvements of the Garden and its amenities were effected during the past twenty-eight years of his service by introducing and acclimatizing many plants both in the Lloyd Botanic Garden, Darjeeling, and the Indian Botanic Garden, Calcutta. The Lloyd Botanic Garden, Darjeeling, was reorganized into a Phyto-Geographical Garden by arranging the plants according to their proper classified order. Dr. Biswas takes keen interest in the cultivation of medicinal plants in India. It was at his initiative that the Government of West Bengal started the cultivation of plants yielding some important drugs in the Eastern Himalaya (Rungo) under the joint auspices of the Medicinal Plants Committee of the West Bengal and of the Medicinal Plants Scheme of the Indian Council of Agricultural Research. During his regime extensive collections were added to the Botanic Garden Herbarium from South Burma, Naga Hills, Manipur (Assam), Sikkim, Orissa, Bihar (Santhal Parganas), etc. In India he has received many honours, such as the Elliot Medal and Bruhl Medal of the Asiatic Society of Bengal. He was president of the Botany Section of the Indian Science Congress in 1943, president of the Botanical Society of India in 1952 and president of the Botanical Society of Bengal during 1948–50. He is honorary lecturer in botany in the University of Calcutta.

## Dr. D. Chatterje

Dr. D. Chatterjee, systematic botanist at th Indian Agricultural Research Institute, New Delhi has been appointed to succeed Dr. Biswas. Dr Chatterjee was born at Chinsurah, near Calcutta on April 2, 1911. He studied botany at th Presidency College, Calcutta, where he specialized in systematic botany. Later, he went to the Universit of Edinburgh and was awarded the Ph.D. degree o that University in 1939. His work in Edinburg consisted of a critical study of the distribution of th Himalayan and Indian flora. On his return to Indi in 1939, Dr. Chatterjee worked for some time at th Indian Botanic Garden, Calcutta, and in 1940 wen to Burma as a lecturer in botany in the Agricultura College, Mandalay. The War in Burma, however did not allow him to stay there long and he returne to India in April 1942. He worked again at th Indian Botanic Garden, Calcutta, for nearly a year and later, in July 1943, he was appointed a lecture in botany at the Cotton College, Gauhati, Assam He again went to Britain early in 1946 and joine the Royal Botanic Gardens, Kew, London, as botanis for India, from which he published some valuabl papers dealing with new discoveries of several plant and on nomenclature of plants. In 1948, whil working at Kew, he was deputed by the Governmen of India to attend the Symposium on Botanica Nomenclature held at Utrecht, Holland. Dr. Chatterjee returned to India from Kew in April 1949 an was appointed systematic botanist in the India Agricultural Research Institute, New Delhi, in Jun 1949. While there he published papers dealing wit the origin of cultivated rice and other cultivate plants. He has also taken up the classification o cultivated wheats of India. In appreciation of hi work on Indian flora, Dr. Chatterjee was mad a vice-president of the International Botanica Congress held in Paris in 1954, and was awarde a Special Centenary Medal of the Société Botaniqu de France. He was also awarded the Bruhl Memoria Medal of the Asiatic Society of Bengal this year (1955) for meritorious work done in the field of botanica research during the past five years. Dr. Chatterjee ha travelled widely and has worked in several Europea herbaria and botanical gardens. In view of his lon experience in taxonomy and nomenclature, we fee confident that Dr. Chatterjee will prove a very abl superintendent of the famous Botanic Garden a Sibpur, Calcutta.

## conomic Factors in World Peace

In his Alex Wood Memorial Lecture, "The Recon-iling Spirit and the Economic Order", delivered in Glasgow on February 19, and which has now been ublished (pp. 17. London: Fellowship of Recon-iliation, 1955; 1*s*. 6*d*.), Prof. C. F. Carter analyses rst the several arguments that the causes of war re primarily economic. He believes that economic actors have played only a subsidiary part in the reat conflicts of this century, that we are justified n thinking that we are achieving more, and not less, willingness to consider the interests of others and hat pacifists have drawn too sharp a distinction etween police action and war. Economic wrong, waste and injustice still have to find their remedy; ut, as Prof. Carter points out, we cannot afford to do without the great efficiency of large-scale factory production and, while the capitalist system can show examples of ruthless or dishonest profit-making, it can also show many of disinterested public service. Any other way of running our economic affairs would equally depend on much the same human beings, nor is there a simple choice between a system based n competition and one based on co-operation; both xist in any economic system. Inequality and competition between individuals result from our need for a discipline to help us give of our best in production, and such a discipline is not necessarily a bad thing. The conflict between management and labour is not necessarily to be removed by a change to public ownership but by better techniques of management —a more imaginative understanding of the other man's work and aspirations. While, therefore, we should not ascribe to a particular economic system difficulties which would be inherent in any economic system and should distrust the simple solution, Prof. Carter pleads for greater efforts to understand the position of the other man, to see the good in that and the evil in our own, and to be solid and sensible n our proposals for change. Anything we can do to increase personal knowledge about those with whom we are in an economic relationship can be a way of lessening conflict.

## Mount Everest Foundation

A Mount Everest Foundation for the support of scientific work in mountain regions has recently been set up by the Royal Geographical Society and the Alpine Club with funds acquired from the proceeds of the books, film, lectures and other activities which followed the successful Everest Expedition of 1953, sponsored by the two bodies. Within the broad object of supporting the exploration of mountain regions, the Foundation will particularly aid moun-aineering expeditions exploring, to some extent at east, little-known or unknown territory, but not necessarily engaged in a particular branch of scientific research; but provision is also made, more specifically, for the support of scientific investigations in mountain country, not necessarily involving special mountaineering technique, or new exploration in a geographical sense. In this scientific field, grants may be made for research into geography, topography, geology, ethnology, meteorology, botany, zoology, entomology, glaciology, and allied studies, either in, or concerned with, mountain regions; physiological studies dealing with the effects of altitude upon the human organism, and the means of countering such effects, are also among the objects of the Foundation. Those seeking grants should write for application forms to the Honorary Secretary, Mount Everest Foundation, c/o Alpine Club, 74 South Audley Street, London, W.1. The forms should reach the Foundation not later than February 1, April 1 and October 1 each year, for consideration in April, June and December, respectively.

## New Nature Reserves in Britain

The Nature Conservancy on July 28 announced the establishment of three new nature reserves. The first of these, the Wychwood Forest Nature Reserve, covers about 647 acres of mixed woodland, about seven miles west of Woodstock. The mixed fauna and ground flora are rich, and it is intended that the reserve shall be a permanent forest, regenerating naturally and consisting of indigenous species of hardwoods on a long rotation. The reserve will be used for scientific research and will not be open to the public. The Tring Reservoirs Nature Reserve covers an area of 50 acres of the banks only of the four reservoirs, Wilstone, Marsworth, Little Tring and Startopsend, which when full have a combined water area of more than 200 acres. The marshy ground provides a habitat for plants such as the round-fruited rush (*Juncus compressus*), the orange foxtail (*Alopecurus aequalis*) and the broad-leaved ragwort (*Senecio fluviatilis*), which are rare in Britain; but the reservoirs are best known to naturalists as a bird sanctuary, and in 1938 were the first recorded site in Britain for the nesting of the little ringed plover. The nesting species include shoveller, teal, pochard and tufted duck, little and great crested grebe, reed warbler and sedge warbler. Permits will be necessary for those wishing to undertake research, collect specimens, or to visit parts of the reserve away from the footpaths. The Hales Wood Nature Reserve covers only twenty acres about two and a half miles from Saffron Walden, and is one of the best known examples in Britain of oak–ash woodland on chalky boulder clay where the true oxlip (*Primula elatior*) has replaced the primrose in the herb layer. The shrub layer consists mainly of hazel, with occasional maple, blackthorn, dogwood and the large guelder rose; as the wood must be kept undisturbed, access permits can be granted only in very limited numbers and for special reasons.

## Department of Scientific and Industrial Research

In a written answer in the House of Commons on July 21, Mr. J. R. Bevins, Parliamentary Secretary to the Ministry of Works, as representing the Lord President of the Council, gave the names of the members of the committee which is investigating the work of the Department of Scientific and Industrial Research as follows: Sir Harry Jephcott (chairman), chairman and managing director, Glaxo Laboratories, Ltd.; Mr. C. H. Andrew, deputy secretary, Board of Trade; Sir Hugh Beaver, managing director, Arthur Guinness, Son and Co., Ltd.; Mr. E. W. Playfair, third secretary, H.M. Treasury; Sir Alexander Todd, professor of chemistry, University of Cambridge.

## Recent Lunar Research

A paper by Dr. H. Percy Wilkins which appears in the *Journal of the British Interplanetary Society* (13, No. 6; November 1954) is the first of a series of papers which are to appear dealing mainly with changes in lunar topography. Dr. Wilkins returned recently from a tour of the United States where, as he describes it, "with traditional courtesy and hospitality the giant American telescopes were freely placed at my disposal . . .". The instruments that he used were the 60-in. reflector at Mt. Wilson Observatory and the 26-in. refractor at the Naval Observatory, Washington. An account is given of his observations on cracks and clefts, the first object dealt with being the crater of Vendelinus. In 1891, T. Gwyn Elger, the first director of the Lunar Section, British Astronomical Association, observing this crater with his 8½-in. Calver reflector, saw a cleft or crack running north from a small crater on the northern part of the interior, and Elger recorded this cleft later, additional confirmation being obtained by Dr. W. H. Maw's observations with his 6-in. refractor. Wilkins and other experienced observers failed to find a trace of it, and the remarkable thing is that not only did the 60-in. telescope reveal no cleft, but where it once appeared Wilkins saw elevations. Perhaps more remarkable still is the fact that though the cleft had vanished, two new ones had opened up, one on each side of its former position. An examination of Mare Humorum with the Washington 26-in. refractor showed that the border of this plain, which had been known to be extensively cracked, was much more cracked than had been previously suspected. Five clefts seem to be new and one marking shown by the older observers as a ridge is now a cleft. These are only two instances, supported by a considerable body of evidence, and suggest that cracks are still being formed.

## Excavations at Kirkstall Abbey, near Leeds

The Thoresby Society has been excavating for a number of years at Kirkstall Abbey, near Leeds, and the fifth report of the Society, covering 1954 (pp. 16+2 plates; from the Society, Leeds; 1955; 1*s*.), describes an interesting find of a large earthenware crucible. The crucible is 17¼ in. high and 17¼ in. in diameter at the top, decreasing to 11¼ in. at the base, and was used for refining copper or bronze. Metallurgical methods and processes, whether used in the Bronze Age or in later medieval times, are always of interest, and the new find adds considerably to our knowledge of how the folk of this latter period worked. A general account of metallurgical processes is also given, and this will be welcomed by students of many different periods who have not had any training in chemical studies.

## A Museums Calendar for British Museums and Art Galleries

For many years the museums, art galleries and cognate institutions in Great Britain have suffered from a lack of current and reliable information concerning themselves and allied institutions. At one time and another directories have been issued, but these are costly compendiums and are soon out of date. The Museums Association has recently issued an excellent "Museums Calendar" which contains an almanac for 1955, various details of the Association, including notes on its past history, regulations for both its diploma and technical certificate, a complete list of institutional and personal members, and a list of all the museum and art galleries in Great Britain. Details of the present policy of the United Kingdom Carnegie Trustees towards museums are given, as well as particulars, with a useful map, of the regional federations. For the present issue it was only possible to collect information regarding certain overseas museums and art galleries, but in subsequent annual editions, to be issued in January, this feature will be greatly extended. Such a publication is indispensable for those working in, or associated in any way with, British museums and art galleries. In stiff paper covers, it is published at the reasonable price of 5*s*. and can be obtained from the Museums Association, 33 Fitzroy Street, London, W.1.

## Distribution Maps of Scandinavian Species of *Hieracium*

During the last few years of his life, Prof. Gunnar Samuelsson was engaged on a compilation of some of the main features of the plant geography of the Scandinavian *Hieracium* flora. To this end he had prepared distribution maps of more than a hundred species. At the time of his death in 1944 these maps were in a more-or-less complete state; but they had not been worked up or commented on in any way. This has now been done by Erik Almquist, the work being available as a publication of the *Kungl. Svenska Vetenskapsakad. Handl.* (Fjärde Serien, 5, No. 3 1954). This monograph includes 123 maps and a short foreword and index. According to the editor, "Samuelsson's main intention seems to have been to bring to light a number of different distributive types, and to show, at the same time, how far we have come in our knowledge of the occurrence of the more important species". The commentary in the foreword on the distribution of different species and groups is brief; but a number of interesting points are made. In particular, the view is expressed that, although most species of *Hieracium* are in various ways favoured by cultivation, the maps nevertheless afford a fair indication of their natural distribution, certainly of the species of at least some sections of the genus. It is held that spreading of a synanthropic kind over large distances is unusual. Species of other sections, on the other hand, are more-or-less entirely associated with localities under cultivation; but the bulk of the area's species "undoubtedly consists of endemic small species of varying age, having mostly emerged in post-glacial time".

## Speciation and Variation in Asexual Fungi

In a monograph under this title, published under the editorship of R. W. Miner, as Vol. 60, pp. 1–182 (1954), of the *Annals of the New York Academy of Sciences*, readers will find a rich collection of well-illustrated information on this important botanical topic. As Dr. K. B. Raper says in the introduction: "I do not believe that we are dealing with problems basically different from those faced by an investigator concerned with the taxonomy of micro-organisms. In the so-called asexual fungi, however, these problems become particularly acute. The very fact that these organisms reproduce themselves so successfully without the intervention of sexuality at once precludes from consideration a developmental phase with attendant characteristics and structures which, if present, would normally provide the most stable features possible. In the absence of such features, we must somehow get along with what is left". The individual contributions cover a wide range of mycological themes, such as interrelationships of speciation, type preservation, and nomenclature in bacteria; variation and speciation in the genus *Fusarium*; the evolution of species concepts in *Aspergillus* and *Penicillium*; spontaneous and induced variation in selected stocks of the *Penicillium chrysogenum* series; experimental control of morphogenesis in micro-organisms; natural and cultural variation in entomogenous Fungi Imperfecti; types of variation in Actinomycetes; variation and criteria of speciation in the genus *Streptomyces*; 'Ektachrome' transparencies as aids in Actinomycete classification; induced mutation and strain selection in some industrially important micro-organisms; morphological studies in the genus *Nocardia*.

## Statistics of Petroleum Products in Britain

STATISTICS recently issued by the Petroleum Information Bureau on behalf of the Petroleum Industry Advisory Committee reveal that in 1954, for the first time, the United Kingdom used more than twenty million tons of petroleum products (excluding bunkers for ships engaged in foreign trade). Actual total inland consumption was 21,038,511 tons—more than two million tons increase on the corresponding figure for 1953. Of this total, nearly six million tons represents motor spirit (including motor benzole); 1·3 million tons burning and vaporizing oils; 1·4 million tons derv fuel; 6·3 million tons gas, diesel and fuel oils. Consumption of all other petroleum products showed substantial increases over corresponding figures for 1953. Of indigenous materials made available for distribution in the United Kingdom by the industry, motor spirit by low-temperature carbonization and also refined benzole showed increases compared with 1953.

## Library of the University of Leeds: Report for 1953–54

THE annual report of the Librarian of the University of Leeds for the session 1953–54 (pp. 11; Leeds, 1954) records holdings of books and pamphlets totalling 540,770 on June 30, 1954, accessions during the year totalling 13,347 volumes, 2,421 pamphlets and 25,086 periodical parts. Of these, 6,503 volumes and 1,684 pamphlets were presented, while many books and periodicals were obtained by systematic exchange, particularly with the Biblioteca Apostolica Vaticana, the British Museum, the Library of Congress, Societas Entomologica Fennica and the Universities of Berne, Helsinki, Marburg, Münster and Zurich. The second instalment of the new stack and mezzanine floor has given complete satisfaction both on practical and aesthetic grounds, and it is hoped that the scheme will be completed in the near future by the addition of the two surrounding portions which will bring the new floor to the outer perimeter and make provision for research readers. There was an increase of 5 per cent in cataloguing done during the year; but the position of the Medical Library further deteriorated, and there is now insufficient space for text-books and monographs and the commonly used periodicals. Plans have been made for a small extension of the building which it is hoped will have been undertaken early this year.

## Chemistry and Biology of Phospholipids: Symposium in London, Ontario

THE Biochemistry Division of the Chemical Institute of Canada is sponsoring a symposium on phospholipids, to be held in the University of Western Ontario, London, during October 12–13, immediately preceding the meeting of the Canadian Physiological Society. The symposium will consist of two sessions on the following topics: chemistry of phospholipids (chairman, A. M. Wynne, University of Toronto), at which phosphoglycerides, inositol phospholipids and sphingolipids will be discussed; and metabolism and function of phospholipids (chairman, W. R. Bloor, University of Rochester, New York), at which their biological synthesis, metabolism *in vitro*, and function will be discussed. Members of the Canadian Physiological Society and others interested may attend the symposium. There will be a registration fee of one dollar. Further information can be obtained from Dr. R. J. Rossiter, Department of Biochemistry, University of Western Ontario, London, Ontario.

## Announcements

SIR ARNOLD HALL, director of the Royal Aircraft Establishment, Farnborough, since 1951 (see *Nature*, 168, 19; 1951), is retiring and will join the Hawker Siddeley Group as technical director. He will be succeeded at Farnborough by Mr. G. W. H. Gardner, director-general of technical development (air) at the Ministry of Supply.

THE Council of the Physical Society has made the following special awards for 1956: *Guthrie Lecture*, Sir Francis Simon; *Rutherford Lecture*, Prof. P. I. Dee; *Duddell Medallist*, Prof. J. G. Gaunt; *Charles Vernon Boys Prize*, Dr. G. D. Rochester and Dr. C. C. Butler.

THE Executive Council of the Commonwealth Agricultural Bureaux has elected Mr. J. E. C. Coventry, representing the Federation of Rhodesia and Nyasaland, as its chairman, in succession to Mr. W. F. C. Morton, who represented the Union of South Africa. Mr. A. L. Perera, representing Ceylon, has succeeded Mr. Coventry as vice-chairman.

DR. HELEN MARGUERITE MUIR-WOOD, principal scientific officer in the Department of Geology, British Museum (Natural History), has been appointed deputy keeper in that Department. Dr. Muir-Wood is a graduate of the University of London (Bedford College and University College) and went to the British Museum (Natural History) in 1922. She was given charge of the Brachiopoda, on which group she has published a number of monographs and papers.

DR. T. A. M. NASH, deputy director of the West African Institute for Trypanosomiasis Research, Kaduna, Northern Nigeria, has been appointed director of the Institute, the appointment dating from October 17, 1954, when Colonel H. W. Mulligan retired. Dr. Nash, who is well known for his work on the ecology and control of tsetse flies, has been connected with the Institute as chief entomologist and deputy director since its inception in 1948; he has been engaged in tsetse work since his first appointment to Tanganyika Territory in 1927.

IT has been decided to change the name of the Royal Sanitary Institute; it will be known in future as the Royal Society for the Promotion of Health.

THE Chemical Research Laboratory (Department of Scientific and Industrial Research), Teddington, Middlesex, is having open days during September 27–29. Applications for invitations should be sent to the Director not later than August 31; those already on the mailing list need not re-apply.

THE Institution of Chemical Engineers and the Society of Instrument Technology have arranged a joint conference on "Automatic Control in the Process Industries", to be held at the Caxton Hall, London, S.W.1, on October 4. Further particulars can be obtained from the General Secretary, Institution of Chemical Engineers, 56 Victoria Street, London, S.W.1.

# PROBLEMS OF INTERNATIONAL CONCERN IN THE BIOLOGICAL SCIENCES

DURING the Twelfth General Assembly of the International Union of Biological Sciences, held in Rome in the rooms of the Consiglio Nazionale delle Ricerche during April 12–16, a symposium was held on "Problems of International Concern in the Biological Sciences" with the aim of discussing some possible lines for the future work of the Union. The symposium was centred around seven major topics, and the discussion of each was introduced by a panel of three. In each panel one of the three acted as the chairman of the discussion.

For the first topic, "Standards, Units, Symbols and Terms", A. Frey-Wyssling (Botanisches Institut, Zurich) was chairman, and J. H. Burn (Department of Pharmacology, Oxford) and E. Hadorn (Zoologisches Institut, Zurich) were the main speakers. It was recommended that the Union should urge the universal adoption of the decimal system for international scientific publications: editors of international periodicals should be requested to convert all units into the decimal system if the authors had not already done so. A more general resolution aiming at promoting the unification of standards, units, symbols and terms in the field of biology was adopted by the General Assembly. Dr. Burn discussed the successive steps in the co-ordination of international standards for substances demanding biological assay. The matter is now regulated by an organization established under the auspices of the United Nations World Health Organization, which is working well. Dr. Hadorn's speech was especially concerned with the work of the Committee on Genetical Nomenclature and Symbols. It is planned to have a conference on this topic immediately before the next International Congress of Genetics, which is to be held in Montreal during 1958.

The second topic dealt with the "Organization and Support of Research", with R. E. Cleland (Botanical Institute, Bloomington, Ind.) as chairman, and C. F. A. Pantin (Zoological Laboratory, Cambridge) and B. Rajewsky (Max-Planck-Institut, Frankfurt-am-Main) as main speakers. The matter was thoroughly discussed, and finally it was suggested that the International Union of Biological Sciences should attempt four things: to persuade countries to undertake co-operative solutions of problems which transcend national boundaries; to make pronouncements on matters of world-wide scientific concern where the welfare of science is threatened by considerations involving the interests of individual nations; to organize programmes of research which cannot be organized by individual nations; to devote some of its time to the consideration of future trends in biology, and of how certain major problems of biologists, such as publishing, can be solved in the future (to this end the Union might sponsor symposia from time to time on such topics, either at the time of the General Assembly, or independently).

The third topic, "Teaching and Training", was introduced by P. Weiss (Rockefeller Institute, New York). The invited speakers were Chr. P. Raven (Zoologisches Laboratorium, Utrecht) and W. Ankel (Zoologisches Institut, Giessen). The discussion centred around the dilemma, clearly pointed out by Weiss, that, on one hand, biology has developed from many independent branches which are gradually discovering their common principles, thus calling for a deliberate integration; and, on the other, that the increasing volume of biological research and the spectacular advances in certain lines are fostering a dispersive tendency toward further fragmentation. The rate of progress in the biological sciences will depend to a great extent on the rate at which biological teaching can be made to cope with these conflicting trends and adapt itself to the changing situation. Students should be prepared for the biology of the future rather than educated in that of the past.

The subject of the fourth topic was "Publications", and for this M. J. Sirks (Genetisch Instituut, Haren) was chairman, with B. Glass (Department of Biology, Baltimore, Md.) and P. Rosbaud (Pergamon Press, Ltd., London) as panel members. The international support of periodicals should go first to the abstracting and indexing periodicals; second, to review periodicals and book series; third, to handbooks of data, indexes, lists of materials and workers, dictionaries of symbols, etc.; and lastly, to monographs of a costly and truly international scope.

In view of the magnitude of the literature to be surveyed, the abstracting and indexing journals must begin to co-operate and co-ordinate their efforts. It was recommended that they apply for admission to the Abstracting Board of the International Council of Scientific Unions and that they work out a co-operative plan. Since both general and specialized abstracting periodicals are for the present necessary, the latter should provide the former with a selected coverage of special fields, and each of the former should undertake to cover completely a nucleus of journals not dealt with by the other general abstracting services. Review periodicals and book series should be subsidized so far as possible in order to reduce their present high cost to users throughout the world. Co-ordination should be developed to prevent simultaneous reviews of the same subject in different places.

The recommendations to the Executive Committee of the International Union of Biological Sciences with regard to the fifth topic of the symposium, "Supplies and Depositories" (Dr. L. Harrison Matthews (Zoological Society, London) chairman, with A. van Straelen (Museum of Natural History, Brussels) and J. Westerdijk (Centraalbureau voor Schimmelcultures, Baarn) as panel members), were threefold. *Living materials.* The appointment of a small international committee to study the problems of the supply of laboratory animals, the cataloguing of users and of sources of supplies, the definition of standards and related matters on an international scale; representatives of the Division of Botany and of the Sections of Microbiology and Genetics should be included in the committee to advise upon the matters relating to their subjects. *Museum collections.* While the documentation of botanical type specimens ppears to be satisfactorily in progress, the same annot be said for zoological type specimens. It ight be useful to ask a small panel of zoologists to raw up recommendations for the preservation, ollection and cataloguing of zoological type specimens, the distribution of co-types and para-types, nd the safeguarding of the type specimens in times f international emergency. *International expeditions.* Unesco should be advised when international expeditions are under consideration, both for the selection f personnel and for the distribution of specimens ollected.

The chairman for the sixth topic, "International Congresses and Conferences", was J. Runnström (Wenner Grens Institutet, Stockholm), and the invited speakers were Sir Gavin de Beer (British Museum (Natural History), London) and P. Chouard (Conservatoire National des Arts et Métiers, Paris). The main conclusions of the discussion of this very important topic were as follows. The large international congresses should not be suppressed; their need is still very great in the biological sciences to avoid the danger of over-specialization. Their rhythm should be one of four or five years. The congresses should include a number of symposia introduced by at least two invited speakers with divergent views or with a divergent approach to the subject. Discussion from the floor should be allowed after the introductory papers. Uninvited short papers should be submitted to previous scrutiny, as is customary for the acceptance of a paper in a scientific journal. It was also decided that specialized conferences (symposia) with no more than twenty to twenty-five participants should be held between the general congresses. The Executive Committee of the Union should study the question of publication of the proceedings of the symposia in order to reach a certain degree of uniformity.

The last topic of the symposium, which dealt with "International Co-operative Projects", should have been introduced by B. Rensch (Zoologisches Institut, Münster), but he was unfortunately not able to attend, and J. Runnström took the chair in his place; Dr. Rensch's paper was read by Dr. L. Harrison Matthews (London). R. Hiatt (Hawaii Marine Laboratory, Honolulu) and E. Aichinger (Landesinstitut für Pflanzensociologie, St. Georgen am Sandhof, Austria) were the two invited speakers; but the latter was absent. Rensch expressed the opinion that the barriers raised by differences in language are greater than they should be, and that more personal contact would help to remove these hindrances to the more complete utilization of scientific experience. In some fields of biological research, international co-operation is imperative: such are the biological problems presented, for example, by the oceans and the polar regions. International co-operation is also essential within certain borderline fields between biology and other sciences, as, for example, biometry, biophysics and biological philosophy. Hiatt's special concern was international co-operative projects in marine biology; this matter was more exhaustively discussed in a symposium on marine biological laboratories held under the auspices of the Union a week later (see *Nature*, June 18, p. 1062).

In conclusion, it may be said that many of the resolutions or suggestions which came out of the discussion at the symposium were adopted by the General Assembly of the International Union of Biological Sciences, or will guide the future policy of the Executive Committee of the Union.

# BREEDING LABORATORY ANIMALS

THE use of laboratory animals in nearly all branches of biological research has been steadily increasing for several decades and, as was to be expected, it has kept in step with the general increase in work of this kind. Moreover, the usefulness of animals, and in particular of the smaller mammals such as the common laboratory rodents, in investigating and assaying drugs and other therapeutic substances not susceptible to chemical standardization accounts to-day for a very large proportion of all laboratory animals used in Britain and in most other countries[1]. Concomitant with this increased use has developed the demand for quality, so that to-day laboratory animals tend to be regarded more or less as reagents. Among the essential qualities of any reagent are some indication of its purity, or at least its degree of contamination, and also the requirement that it should be perennially reproducible. This implies that attention must be given to the methods of producing these biological reagents[2].

In the past much reliance has been placed upon animals supplied by breeders or dealers whose main interest is to offer suitable animals for sale upon such terms as will afford them reasonable business profits. There is much to be said for this system in that it relieves laboratory workers of the burden of manufacturing their own reagents, and, provided the quality of the animals supplied in this way is of a high enough standard, there is every reason to suppose that the commercial breeder or supplier will remain in the field indefinitely.

This proviso, however, is an important one, because to-day the laboratory worker's demands for animals of a given specification are more exacting than ever before. For certain types of animal, commercial sources cannot hope to provide suitable material, and the laboratory worker is driven, often rather reluctantly, to breed his own animals. Such instances as inbred strains of mice for cancer research, and the production of litter-mate groups, may be cited. It has now become quite evident that, in order to obtain animals of the quality required, it is often necessary to breed them under laboratory conditions and in considerable numbers—numbers such as will satisfy the greater part of the demands of, say, all the laboratories of a single university.

It was therefore timely that a symposium on the breeding of laboratory animals should have been arranged by the Laboratory Animals Bureau, and was held at the Royal Society of Medicine on May 9, with Prof. E. C. Amoroso, of the Royal Veterinary College, London, in the chair. The papers read at the symposium will be published in the "Collected Papers", Vol. 3, of the Laboratory Animals Bureau (obtainable from the M.R.C. Laboratories, Holly Hill, Hampstead, London, N.W.3).

Mr. A. L. Bacharach (Glaxo Laboratories, Ltd.) opened the symposium with a paper entitled "Some Aspects of Animal Production for Routine Biological Assay". He treated his subject mainly from the point of view of the user, and he drew largely from his experience of the colonies of rats and mice which have been maintained for many years by the Glaxo Laboratories at Greenford. These colonies were set up in order to fulfil the exacting demands of the bio-assayists, and Mr. Bacharach played a prominent part in their establishment. Experience at Greenford has shown that ample reward in the way of more uniform animals, and therefore better reagents, has been obtained, not only by closely regulating the environment in which the animals are bred but also by achieving further uniformity through inbreeding. The combination of genetic uniformity and an optimum uniform environment has added little to the cost of animal production.

Dr. H. Grüneberg (University College, London) spoke about "The Genetical Aspects of the Breeding of Laboratory Animals". In considering whether uniformity might be best achieved by the use of strictly inbred animals, by their first- or second-generation crosses, or by randomly mated members of a comparatively large population, he directed attention to the fallacy of *a priori* reasoning. In respect of some thirty-one morphological characteristics in mice, he showed that the variance in inbred strains and in their *F*1 and *F*2 crosses is quite unpredictable. The inbred strains may have a high or low variance for any particular characteristic; so also may crosses between strains, and it may be greater or less than that of either parent strain, so that in any single instance the degree of variance can only be discovered by investigation. What is true for morphological features is likely to be equally true for physiological responses. It follows that for every test where maximum uniformity is of value the merits of each case must be examined individually[3].

The third paper was given by Dr. D. Michie (Department of Zoology, University College, London) and was entitled "Towards Uniformity in Experimental Animals". Dr. Michie pointed out that, whereas inbred strains possess the maximum genetical uniformity, the phenomenon of inbreeding decline may render them particularly sensitive to small changes in the environment. In this way the phenotypic variance may be, and frequently is, greater than is to be expected on the assumption that variance from genetical and environmental causes is merely additive. If, however, two inbred but comparatively unrelated strains are crossed, the resulting progeny will possess a full measure of hybrid vigour because they will be to a large extent heterozygous; but, because their parents are homozygous, the genetical pattern of the first generation progeny will be as uniform as that of the parents. In such an instance, therefore, it is possible to obtain genetically uniform animals with all the vigour conferred by the heterozygous state and thus far less susceptible than their parents to small changes in the environment[4,5].

Dr. Anita M. Mandl (Department of Anatomy, University of Birmingham) spoke about "The Value of Litter-mate Controls in Endocrinological Research". For this type of work her own experience leaves no doubt that in problems involving a limited number of treatments the use of litter-mate controls gives far greater accuracy, or conversely requires far fewer animals, for a given degree of accuracy. This does not necessarily follow, she continued, in the field of bio-assay. Indeed, for much work of this kind it may be difficult to provide litter-mate controls.

The points arising from the morning session of the symposium emphasized once again the importance of choosing the right animal for the purpose. No rules, are generally applicable to every case, but time spent on making a proper choice will be more than counterbalanced by increased accuracy or by economy in the use of animals. As Dr. Mandl pointed out, the recording necessary to produce animals of known family history is a burden so small as to be almost negligible.

The afternoon session was opened by Prof. J. E. Nichols (Department of Animal Husbandry, University College of Wales, Aberystwyth), who discussed "The Principles of Animal Production". He referred to the production of farm animals for particular purposes, and it was implicit in his remarks that breeding, for example sheep, for special characteristics involved the same principles as breeding laboratory animals. There was much to be learnt about the breeding of laboratory animals from a study of modern farm-stock breeding practice.

Dr. J. S. Perry (formerly of the Agricultural Research Council Field Station, Compton, and now at the Agricultural Research Council Institute of Animal Physiology, Babraham) gave a paper on prenatal loss as a cause of reproductive wastage. By no means every ovum shed may be fertilized, and there is an inevitable and variable loss from among those fertilized which never survive to be born. Whether or not this almost universal prenatal wastage has a value under natural conditions, there can be no doubt that in the less rigorous environment of the laboratory it is worth attempting to reduce it so that the maximum reproductive potential may be more nearly approached.

Dr. I. W. Rowlands (Institute of Animal Physiology, Babraham) spoke on postnatal causes of reproductive wastage. There is little advantage, he said, in an embryo surviving the hazards of uterine life only to succumb to the further hazards of the period between birth and weaning. Some of these latter hazards are inherent in the dam or the offspring. Others, however, are largely influenced by the circumstances of the breeding colony. In either case losses should not be accepted with complacency.

The last paper was given by Dr. C. S. Grunsell (Royal (Dick) School of Veterinary Studies, Edinburgh); Dr. Grunsell is curator veterinarian of the small-animal breeding station at the University of Edinburgh, and he spoke from his own experience of the problems besetting anyone in such a position. One of these problems is the old one of fluctuating demand which too seldom keeps in phase with supply. A university breeding station serving a single university, he said, is probably the right sort of size to aim at and has the advantage of administrative convenience. It should be capable of supplying most of the requirements of different university departments for most species of laboratory animal. At least in its early stages it cannot be expected to produce animals down to an economic figure, and perhaps it may never compete successfully in terms of hard cash with the commercial market, although it is impossible to say that this must necessarily be so. It should, however, provide a much better service to university departments than they can generally obtain either from the commercial market or from setting up departmental, and usually thoroughly uneconomic, units of their own.

As Prof. Amoroso pointed out in his summary, we are not far removed from the beginning of our knowledge in this important field, and it would be premature at this stage to pay too much attention to the economic aspect. Indeed, comparatively little is known even about the actual cost of breeding laboratory animals. Those laboratories that do possess figures show as great variations in their costs of breeding as they do in their methods, and too many laboratories appear to have little or no idea of ust how much their animals are costing them. But he cost of breeding is only one item. The cost of asted time and frustrated research resulting from he use of unsuitable or inferior animals can never e properly calculated. One point, however, is clear eyond doubt: the breeding of laboratory animals no longer a matter for the amateur, if indeed it ver was. It has become a special subject in its own ght.

The general conclusion arising from points dis-ussed at this symposium is that there is an urgent eed for far more information about the characteris-cs and responses of different types and strains of boratory animals, and that this information should e handled much more than it is on an international asis. For example, it is not sufficient in referring o work in which animals are used to describe them s just 'mice', or even as 'CBA mice', for even a amed inbred strain may not be the same in two ifferent laboratories. Mouse geneticists and cancer orkers have shown what can be done with defining nbred strains of a single species[6], and the "Catalogue f Uniform Strains" of the Laboratory Animals ureau represents a step in a rather different and erhaps more widely applicable direction. More ecently, the "Handbook of Laboratory Animals" f the American Institute of Animal Resources[7] has ade a further contribution. But these lists are nly a beginning. They are in themselves incomplete nd only serve to emphasize the need for a world-ist of laboratory animals, fully annotated and eriodically kept up to date. The preparation of uch a list would be a considerable labour, but the eans of compiling it should not be difficult to find; here can be no doubt of its ultimate great value to ll who use laboratory animals.

# FOURTH COMMONWEALTH HEALTH AND TUBERCULOSIS CONFERENCE

THE fourth Commonwealth Health and Tuberculosis Conference, organized by the National ssociation for the Prevention of Tuberculosis, was eld in the Royal Festival Hall, London, during une 21–24 and was attended by more than thirteen undred delegates from the United Kingdom and the ominions and Colonies, from the United States, and rom various parts of Europe, Asia and Africa. ifty-eight different countries were represented. The cientific programme had been skilfully planned to ppeal to the wide variety of interests represented y chest physicians, radiologists, medical and lay dministrators, industrial medical officers, matrons, urses, social workers and physiotherapists, and con-isted of discussions on the following topics: pre-entive outlook; child hygiene and infection; choice f drugs in medical and surgical treatment of tuber-ulosis; death-rates; X-ray and tuberculin surveys; uberculosis as a problem of different races; psychology of the patient and relatives as a factor in successful treatment; tuberculosis in industry; tuberculosis and leprosy; and rehabilitation.

In the session on the preventive outlook to-day, Dr. P. V. Benjamin, technical adviser in tuberculosis to the Government of India and the first recipient of the Sir Robert Philip Medal of the National Association for the Prevention of Tuberculosis for his outstanding contribution to the control of tuberculosis in India, stressed the many difficulties besetting the introduction of preventive measures on an extensive scale in his country. There are few doctors with a real aptitude for this type of work, and the majority of those specially trained are more interested in the clinical aspects. One of the steps under consideration by the Government of India is a re-orientation of medical education to lay increasing emphasis on prevention and social medicine. A BCG vaccination campaign was launched in 1948, and it is intended that all the susceptible population, numbering nearly 170 million, should be tuberculin-tested and BCG-vaccinated by 1960. So far, more than 57 million people have been tuberculin-tested, and 18 million vaccinated, with an average monthly turnover of 2½–3 million.

In the discussion on the choice of drugs in the treatment of tuberculosis, Dr. Walsh McDermott, editor of the *American Review of Tuberculosis*, described isoniazid as a revolutionary drug which has made possible the domiciliary treatment of the disease in outlying places. There is also a strong possibility that it may be used for prevention. In his experience, isoniazid given alone has proved as effective as, and even better than, combined therapy with streptomycin and *p*-aminosalicylic acid, for example. Dr. O. F. Thomas, of Aintree Hospital, Liverpool, emphasized that, in the absence of reliable laboratory methods for establishing drug sensitivity of the tubercle bacillus, it is all the more important to be familiar with the previous history of drug treatment in any given case. Dr. Brendan O'Brien, of Dublin, presented a preliminary report on the clinical use of a new molecular combination of isoniazid, thiosemicarbazone and starch ('Hinconstarch') in nine patients with varying degrees of tuberculosis, seven of whom became sputum-negative. The drug was well tolerated, and there were no toxic effects on any system. Dr. Frank Retief, chief medical officer to the Witwatersrand Native Labour Association, Johannesburg, communicated an interesting paper on the results of isoniazid therapy in African miners with open pulmonary tuberculosis. The most striking effects were euphoria and increase in appetite. Of the forty-five patients treated, 68 per cent gave a sputum reversal to negative after three months, and 80–90 per cent showed improvement radiologically, particularly during the first four to six weeks after beginning treatment.

In the session on tuberculosis as a problem of different races, Dr. T. F. Anderson, director of medical services, Kenya, stated that, in the absence of specific treatment, pulmonary tuberculosis in the African patient runs a rapidly fatal course; but that the response to modern chemotherapy is extremely good, even in cases showing widespread disease. According to Dr. Riaz Ali Shah, associate professor of tuberculosis at King Edward Medical College, Lahore, many complex and variable factors are concerned in influencing the speed of decline of morbidity and mortality from tuberculosis in various ethnic groups, such as economic factors, genetic elimination of susceptible persons and educational campaigns, so that tuberculosis is inherently not a racial problem.

In the discussion on tuberculosis and leprosy, the late Dr. John Lowe, in a paper read for him by Dr. E. Muir, honorary medical adviser, British Empire Leprosy Relief Association, suggested that the varying susceptibility of different persons to leprosy might be related to the presence or absence of acquired immunity to tuberculosis. Compulsory isolation in his opinion is unscientific, impracticable, ineffective and inhuman. He concluded by saying that leprosy is not a disease apart, but that it is a general public health problem; that public health, and not public fears and prejudices, should determine the policy of leprosy control.

An attractive and informative exhibition, spaciously housed, was organized in conjunction with the conference and included a mass-radiography unit at work; technical apparatus; drugs; books and periodicals; occupational and art therapy; scientific exhibits from various hospitals; examples of work done by administrators, doctors and patients in the British Colonies; and an exhibit of the Ministry of Agriculture, Fisheries and Food illustrating the rapid progress made since the end of the Second World War in the eradication of bovine tuberculosis in cattle. Some very interesting short films were shown, and the conference ended with a number of visits to hospitals, sanitoria and other institutes specially connected with problems of tuberculosis.

W. R. BETT

# MUSEUMS ASSOCIATION

## CONFERENCE IN BIRMINGHAM

FOR its sixty-first annual conference, held during July 4–9, the Museums Association returned to Birmingham, which was last visited in 1932. The 1955 Birmingham conference was, however, about twice as large as its predecessor, being attended by about three hundred and fifty delegates, including fourteen from overseas. The Barber Institute of Fine Arts in the University of Birmingham provided ideal headquarters, with lecture theatres. In the absence through illness of the president of the Association, Sir Leigh Ashton, the chair was taken by the vice-president, Dr. F. J. North. In a presidential message, Sir Leigh paid a sincere tribute to those in industry who are aware of the value of the vital part played by design in the manufacture of consumer goods; he recalled that in the Victoria and Albert Museum, London, are many objects from Birmingham, especially those illustrating the craft of the silversmith. Dr. North then gave a much-appreciated survey of the main activities of the Association during the past year, specially stressing the important acquisition of new headquarters, the increasing value of the diploma, and the initiation of the technical certificate.

Mr. John Summerson (Sir John Soane's Museum, London) gave the first paper, which was on museum buildings as architecture, and said that Smirke's design for the British Museum was in essence the English collegiate conception. In the Oxford University Museum of 1855 progressive ideas came forward, and it may be considered as a conscious attempt to go one better than the great new railway stations of the period. During the afternoon of July the archæological section of the conference had thr papers. Mr. R. L. S. Bruce-Mitford (British Museur discussed the functions of national and local museum as regards the acquisition of material, and he state that the British Museum can now carry out excav tions of its own, and one is now in progress Hodhill in Dorset. Prof. C. F. C. Hawkes (Oxfor outlined the great advantages of "Inventar Archæologica", a handy compendium of selecte material, printed not in volumes but on uniform ar inexpensive cards. These are planned to cover th widest possible range of types, periods and culture and about two hundred British cards should b ready by 1960. Dr. D. B. Harden (Ashmolea Museum, Oxford) concluded the afternoon sessior he maintained that the primary object of the publ in visiting museums is recreational.

On July 6, Mrs. Lydia Bond-Powel described th American Wing of the Metropolitan Museum of Ar New York; this is devoted to the chronologic development of the interior architecture and deco ative arts in the American Colonies and the earl Federal period of the United States. Mr. Io Williams strongly advocated the formation of museum of oil paintings. He stated that there is n museum which collects paintings not primarily a works of art but as paintings. This constitutes serious deficiency in the study of painting, and should be possible for museums to rectify the positio by the formation of reference collections for the a historian. Prof. Ellis K. Waterhouse (Barbe Institute) pleaded for a closer co-operation betwee art teachers and museum officials and the widenin of the fellowship of the Association to include thos who are chiefly concerned with the teaching of ar history. Prof. W. G. Constable (Boston Museum c Fine Arts, Mass.) made a number of suggestion regarding the place of museums in this changin world, some of which were of a rather revolutionar character. Mr. Norman Bertenshaw, describing th organization of the new Museum of Science an Industry in Birmingham and the way in which th Elkington electro-plate factory has been adapted fo the purpose, stated that the policy of the Museum i to stimulate the interest of the visitor rather tha attempt the portrayal of a complete developmenta sequence, since it is felt that the latter is mor properly the function of the national museums. Dr F. Sherwood Taylor (Science Museum, London) abl outlined the functions of museums in relation t children and science, and maintained that it i essential for instruction to be provided throug pleasure; it is desirable that the exhibits should tel their own story and not rely upon written labels Finally, Prof. H. Graham Cannon (University o Manchester) gave an instructive and practical pape on aquaria in museums.

A session, open to the public, was held on July 9 when Sir Mortimer Wheeler gave an admirabl summary of past negotiations regarding State ai to museums in Great Britain and advocated th formation of a museum grants committee comparabl to the University Grants Committee. Sir Georg Dyson, chairman of the Carnegie Trust, felt that th position of museums is illogical in that the Government has accepted responsibility for the nationa museums but defines national as London. Th provinces pay taxes for the national museum grant and are also expected to support their ow museum.

During the week, tours were arranged to the museums of Birmingham and Warwick, an archæoogical site at Weoley Castle, Althorp, the seat of Earl Spencer, and a tour of the canals to Wolverhampton. At the meeting, Dr. F. S. Wallis (Bristol) was elected president for 1955–56, and it was decided o hold the next conference in Amsterdam, probably at the end of June 1956.

# THE NATIONAL OCEANOGRAPHIC COUNCIL

## ANNUAL REPORT FOR 1953–54

THE National Institute of Oceanography is now firmly established at its new premises at Wormey, near Godalming, Surrey, and the Discovery Committee collections and staff are comfortably housed there, apart from a small group still accommodated at the British Museum (Natural History).

In the Institute's report on research during the year April 1, 1953–March 31, 1954*, two topics of particular interest on the physical side are the relationship between waves, wind and swell, and the transfer of nergy between air and sea; these studies have nvolved not only the co-operation of the Liverpool Tidal Institute but also that of the Department of Meteorology of the Imperial College of Science and Technology, London. An expedition, made possible by a grant from the Royal Society, was run jointly with the latter to investigate energy exchange between air and sea at the flat Island of Anegada in the West Indies. Much important data were gathered and will be reported in detail by Prof. P. A. Sheppard, Mr. H. Charnock and others. Several pieces of new apparatus have been developed or improved. These nclude improvements to the electro-mechanical filter of the wave analyser, further developments to the electromagnetic flowmeter and a new type of recording camera which takes 175 ft. of photographic paper. In collaboration with Kelvin Hughes, Ltd., Dr. J. N. Carruthers has developed a 'streamed cone' current meter allowing for instantaneous measurements of current speed and direction.

On the biological side, advances have been made n the study of krill (*Euphausia superba*), which is the main food of the larger animals in the Antarctic. Mr. J. W. S. Marr has been able to establish that this organism is confined to Antarctic waters and lies mainly in the drift from the Weddell Sea and in the East Wind Drift close to the continent. A comparable study of the chætognath, *Sagitta gazellae*, has nearly been completed by Mr. P. M. David. Mr. A. de C. Baker has shown that common species of phyto- and zoo-plankton have a circumpolar range and leaves little doubt that populations are continuous around the antarctic circle. Further work is being carried out on the material brought back from the expedition on the Royal Research Ship *William Scoresby* to investigate the Benguela Current.

There is still much study to be done on the large collections built up under the Discovery Committee, and a number of specialists are engaged on this. The most recent work to be published on these collections was Captain A. C. Totton's monograph on the Siphonophora of the Indian Ocean. Considerable work has been carried out through international collaboration on whale-marking, thanks largely to a number of whaling companies for lending a modern diesel-driven whale-catcher, the *Enern*. In addition, a number of papers by members of the staff have been published which are important to the study of the life-history and migration of whales.

The Royal Research Ship *Discovery II* has been refitted with a number of new items, including an up-to-date radar set and position-finding equipment. The 1954–55 programme includes a study of deep-water movements in respect of density distribution and other factors. The biological work includes new methods of sampling and observing deep-sea organisms. Investigations will also be carried out using the carbon-isotope method for studying photosynthetic activity. In addition, the ship will also provide facilities for the Admiralty, Sir Edward Bullard and the University of the West Indies for various research purposes. After twenty-eight years of service, the *William Scoresby* has sadly been put in the hands of the shipbreakers. She operated largely as a whale-marker, but during the Second World War served as a minesweeper and patrol vessel in the Falkland Islands area; in 1949 she returned to her work of whale-marking, but only managed one cruise in this capacity under the National Oceanographic Council.

This account of the work of the Council is only a brief summary, and of necessity much of interest has had to be omitted; but much credit is due to the Council and to the energies of Dr. G. E. R. Deacon, director of the National Institute of Oceanography, and his staff for the rapid development of research after the major upheaval of changing premises and equipping new laboratories. C. D. OVEY

# THE GOLDEN EAGLE IN AMERICA

THE golden eagle (*Aquila chrysaetos canadensis*) is widely distributed in mountains and adjacent plains throughout much of the northern hemisphere. Its principal breeding-range in North America extends from the Arctic Ocean south into Mexico, westward from the 99th meridian. As it nests from near sea-level to the timber-line, it may be found in a wide variety of habitats and in winter it occurs practically throughout this country. Its food habits are as varied as the diversified habitats in which it lives. These, and the economic status of the eagle, have been described by Lee W. Arnold in a publication of the Fish and Wildlife Service of the United States Department of the Interior (Circular 27).

The golden eagle has been known to kill and eat more than sixty different kinds of animals, ranging from full-grown deer and antelope to mice, birds, frogs and insects. Both living creatures and dead are included in its diet, and at times it accepts carrion even though living prey is available.

Rabbits and rodents form the staple diet of the golden eagle, the proportion taken varying with local conditions. During the nesting season on a Colorado antelope range, rabbits supplied most of the golden eagle's food; under winter conditions on a North Dakota pheasant refuge, they comprised approximately 19 per cent.

On occasion, the bird will kill adult and young antelope, although in northern Colorado, where four pairs of eagles nested in close proximity to antelope at fawning time, such predation was negligible.

Although the golden eagle will kill either the adult or the young of deer, no evidence was found to indicate that the bird is more than a minor influence when compared to other factors controlling deer populations.

Depending on local conditions, the golden eagle exerts a varying pressure on upland game birds, and at times this pressure may be sufficient to warrant eagle control. The harassing of upland game, thus keeping them from feeding properly in severe weather, may be more serious than the actual killing activities of the eagle. When nesting in the vicinity of waterfowl areas, the golden eagle may feed its young largely on these birds.

Golden eagles at times kill domestic lambs. The extent of this damage varies with local conditions. On occasion, they kill calves or may even contribute to the death of full-grown cattle. All evidence indicates that this is an exceptional activity.

Golden eagles occur in varying numbers on more than sixty-five Federal wild-life refuges where, in general, they serve a beneficial purpose in consuming wounded, sick or dead ducks and forage-consuming jack-rabbits and rodents.

## RESEARCH ON FOREST PRODUCTS

THE strength properties of plywood have already been considered in Bulletin No. 29 of the Forest Products Research Laboratory, Princes Risborough, entitled "Comparison of 3-Plywoods of a Standard Thickness, Part 1" (see *Nature*, **174**, 383; 1954). In Bulletin No. 33 on "The Strength Properties of Plywood, Part 2: Effect of the Geometry of Construction"*, the author states that an increasing demand for data on the mechanical properties of plywoods exists; but owing to the wide variety of constructions and thicknesses now available, it is not possible to obtain these data by testing procedures alone. To cover the whole field, some simple methods for estimating strength from limited basic data are required, and this the author sets out to do. This investigation has become necessary because plywoods have become a structural material and can now be produced in forms practically indestructible by delamination. It is stated that increasing quantities are being used, for box and web types of girder, panel floors and walls, ship's planking and concrete shuttering. The trouble is the large variety of thicknesses and different forms of construction, all of which cannot be tested. The coming of plywood in this extensive form of utilization will be very beneficial to the tropical and subtropical forester in charge of forests containing large mixtures of species of trees of which until comparatively recently only a few luxury timbers were marketable. A number of others are now being used, and sylviculturally the management of the forests should become more intensive with the improvement of working plans.

The Bulletin contains the results of an investigation to provide suitable equations for calculating the bending, tension, compression and shear strengths of any plywood construction. All the tests are carried out on African gaboon. From the results, equations
have been formulated which can be used in practi
for calculations or constructions of any other speci
of wood. An appendix to the Bulletin shows ho
they can be applied.

Bulletin No. 32 of the Forest Products Laborato
entitled "Field Tests on Wood Preservatives used f
Pressure Treatment"* describes experimental wo
carried out during 1929–53. The lengthening of t
life of wood for the various purposes for which it h
for so long been used by man has always been a fact
for some consideration, especially in tropical cou
tries where perhaps the matter has been more
the forefront of both forester and wood user.
long ago as the 1860's, when railway construction w
being carried out on an intensive scale in northe
India, the supplies of the valuable Himalayan deod
threatened to give out, and sleepers were cut fro
the *Pinus longifolia* which was abundant in t
lower hills. Creosote was brought out from Brita
and applied cold without any protective effect.
was more than half a century before the ra
way authorities tried this timber again for t
purpose.

In temperate climates, in Europe at least, so
form of preservative for wood structures has f
long been under experiment. So far the hig
temperature creosotes have proved to be the mo
effective preservative under test. The metho
employed is to set out a small 'graveyard' of sm
blocks of a perishable wood (the agar wood is chief
used) and these are treated with graded concentr
tions of the preservative under test, untreated wo
blocks being side by side with the treated ones. Th
treated blocks are kept for a few months with
specific fungus growing on a nutrient agar medium
Periodical examination of the blocks is undertake
one of the tests being done at Princes Risborough,
second at Thetford and the third at Dolgelly. No
is as yet complete.

The results already obtained, however, do give so
indication of how effective most of the treatments a
likely to be. So far, the high-temperature creosot
have proved to be the best preservative under test
all are highly effective, and after twenty years the
is no sign of any difference between them. The lo
temperature creosotes, however, do not appear to
quite so effective. At present there is not much
choose between the various modern water-solub
preservatives under test, although 'Ascu' appears
be the most promising.

## SPITSBERGEN TERTIARY COAL FOSSILS

SVEIN MANUM has reported on the pollen-grai
and spores to be observed in coal deposits
Tertiary age in west Spitsbergen (Norsk Polarinstitut
Med. 79, pp. 1–9; 1954; English summary).

The Tertiary formation, of Palaeocene–Eocene ag
comprises several coal seams of which a preliminar
analysis of the contents of pollen and spores h
now been made. The numbers of microfossils,
well as their state of preservation, are highly variabl
All grains and spores are completely flattened in t
coal and do not regain their round shape after macer
tion. The pollen and spores thus far observed hav

n referred to fifty-two sporomorphs, most of them mbling species already described, in particular n the German lignites. Some twenty sporo- rphs, however, are considered to be new. De- ptions and names have not been attempted in the sent paper; but some of the most characteristic romorphs have been illustrated, and indications their affinities given. A comparison has also n made with the genera that are known as crofossils.

Nathorst mentions six such species of pterido- ytes, while twelve sporomorphs indicate that this up was represented by a considerably larger nber of species. Most of the spores are referable the Polypodiaceae and Osmundaceae. The copodiaceae are not known as macrofossils; but of the spore types seems to belong there.

The gymnosperms are abundantly represented as crofossils (twenty-seven species, among them enty-four conifers) as well as pollen. Among the nged pollen grains some have a strong resemblance *Abies*—a genus not so far found as a macrofossil. nong gymnosperm pollen grains without wings ere are two which somewhat resemble *Sciadopitys* another genus not observed as a macrofossil.

The Betulaceae, Fagaceae and Salicaceae are resented by more than twenty species of macro- sils, and correspondingly a large number of pollen ins belong to this group. Some grains also recall Myricaceae, which, however, are not among the crofossils. Another type resembles the pollen of *er*, of which three macrofossil species have been orded; and so on, materials indicative of affinities th *Alisma, Nymphaea, Potamogeton* and Ericaceae ing recorded. Lastly, some pollen grains have aracters recalling those of certain palms (*Sabal*), ich are known from the Tertiary of Central Europe, t of which no macrofossils have been found in itsbergen.

## GROWTH-SUBSTANCES SEPARATED BY CHROMATOGRAPHY

METHODS for the chromatographic separation on paper of indole compounds, and for the rect biological assay of the chromatograms using e *Avena* coleoptile straight-growth method, have en described by N. P. Kefford (*J. Exp. Bot.*, 6, 16, 9; 1955). Reagents for the detection of the dole-3-carboxylic acids, indole-3-acetonitrile, and amine as coloured spots on chromatograms are mpared, and the areas of such spots are shown to proportional to the logarithms of the quantities substance present.

The procedure of chromatography described is own not to involve a loss of indole-3-acetic acid tivity if chromatography is done in darkness and romatograms are not stored in light and air.

Methods are described for the extraction of growth- bstances from plant materials, the purification and romatography, on paper, of the extracts and the oassay of the chromatograms using *Avena* coleoptile ctions. The ether extracts, containing acidic bstances, of etiolated broad bean and pea shoots d roots, etiolated sunflower shoots, maize roots, d potato etiolated shoots and tuber have been romatographed and the chromatograms bio- sayed.

On all chromatograms three areas active in *Avena* coleoptile section growth are found. One area of growth promotion is shown to be due to indole-3-acetic acid. Another area of growth-promotion and one of growth-inhibition are due to unknown substances, which are named accelerator α (α) and inhibitor β (β) respectively. On chromatograms of potato tuber a fourth growth-promoting area, in addition to those described above, is detected and is shown to be probably due to indole-3-acetonitrile. This or indole-3-pyruvic acid may occur together with indole-3-acetic acid on chromatograms of extracts of immature maize kernels and cauliflower head respectively. On cabbage extract chromatograms the growth-promoting activity corresponding in position with indole-3-acetic acid is shown to be due to this acid alone.

## CONTROL OF FERTILITY BY ANTIMITOTIC AGENTS

By Dr. B. P. WIESNER and Prof. JOHN YUDKIN

Department of Nutrition, Queen Elizabeth College, University of London

WHILE continuing our studies on naturally occurring substances which might be used in the control of human fertility[1], we have also adopted a new line of investigation into this problem. This has been a study of some of the numerous substances which are alleged to have antimitotic activity, in the hope that one or more might prove effective in controlling fertility. These are the reasons which led us to this approach.

First, some types of human infertility, such as disturbances of spermatogenesis and very early miscarriage, are often associated with disturbances of mitosis and cytokinesis. These effects may be limited to the seminiferous epithelium or to the ovum, and the sterility which they produce is usually not accompanied by detectable signs of ill-health in the man or woman. Secondly, mitotic poisons frequently prevent the development of the fertilized ovum of various aquatic animals. In fact, many such poisons have been discovered by exposing echinoderm eggs to them. Again, it has been found that concentrations of a mitotic poison which readily suppress cleavage of the fertilized ovum need not affect the adult organism.

We have therefore studied the effect on pregnancy in female inbred Swiss mice of a number of antimitotic substances, administered in solution or suspension by stomach tube or subcutaneous injection. In all experiments, control animals receiving the dispersing medium in similar manner remained unaffected. Two examples of active substances so far discovered are given here.

*Example* 1. *D-usnic acid*. The antimitotic effect of this compound was described by Marshak and Harting[2]. We administered it daily by stomach tube in the form of freshly made solutions in $N/100$ sodium hydroxide at a dosage-level of 1·5 mgm. Administration begun before pairing had no effect on mating, as shown by the occurrence of a vaginal plug. Administration either before pairing or immediately after copulation was usually not followed by pregnancy but by a recurrence of oestrus and of mating. However, notwithstanding continued administration of usnic acid, there eventually resulted a state of resistance in which copulation was followed by pregnancy. These pregnancies went to term, though the litter-size and growth-rate of the pups suggested somewhat lowered fertility. Some litters were retained and a second generation reared with the view of detecting possible effects upon the progeny; no such effects were observed.

*Example 2. Podophyllotoxin.* The antimitotic effect of this substance was demonstrated by Cornman[3]. We administered podophyllotoxin by subcutaneous injection, either as a solution in aqueous alcohol or as a suspension of microcrystals in water. A single dose of 0·25 mgm. was given to each animal either immediately after detection of vaginal plug or 3, 6, 12 or 14 days thereafter. Pregnancy did not continue in animals treated three days or more after copulation. Administered within twenty-four hours after copulation, podophyllotoxin was only occasionally effective. After interruption of pregnancy, mating again occurred. Podophyllotoxin was again administered, and pregnancy again did not continue. This has been repeated for three successive pregnancies; thus, unlike usnic acid, there is no evidence of a rapidly acquired resistance.

The subsequent fourth pregnancies were not treated and they proceeded to term quite normally. No side effects such as excessive defæcation or vaginal hæmorrhage were detected even in animals allowed to go to the fourteenth day of pregnancy before podophyllotoxin was administered. In each pregnancy, the increase of maternal body-weight corresponded to that of normal gestation. The only systemic effect noted after administration was the rapid loss of gestational gain of weight.

It is possible that the suppression of fertility accidentally observed by Jackson and Bock[4] after the administration of triethylene melamine may not be related to the carcinostatic activity of this substance as such but rather to its more general antimitotic action. As regards podophyllotoxin, Didcock, Picard and Robson[5] have also shown that it interrupts pregnancy at an advanced stage, although their reason for undertaking the experiment was the hypothetical resemblance of tumours to pregnancy. It has been supposed that podophyllotoxin acts by interfering with the blood supply[6]. Since, however, we have found that it prevents the continuation of gestation even before the implantation of the ovum, its activity is more likely to relate to direct action upon the ovum.

Our results encourage us to continue the search for antimitotic substances the ovicidal activity of which may be employed for the screening of agents of possible use in the control of human fertility.

We acknowledge with thanks the gift of D-usnic acid from Mr. H. A. Berens of Messrs. Biddle, Sawyer and Co., of podophyllotoxin from Dr. W. Mitchell of Messrs. Stafford Allen and Co., and of various other compounds from Mr. S. G. Long of Messrs. R. F. Reed, Ltd. We are also indebted to Messrs. Kylon, Ltd., and Messrs. Stafford Allen for financial assistance, and to Mrs. E. M. Blacker and Miss Margaret Rule for technical assistance.

# A METHOD FOR THE LOCALIZATION OF SITES FOR OXIDATIVE PHOSPHORYLATION

By Dr. BRITTON CHANCE and Dr. G. R. WILLIAMS

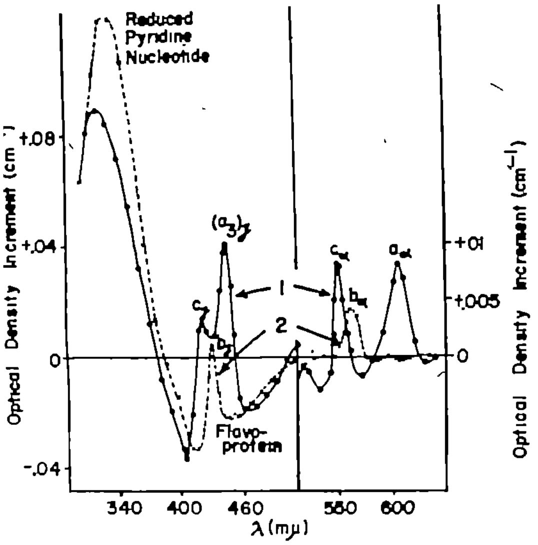
Johnson Research Foundation, University of Pennsylvan
Philadelphia 4, Pennsylvania

ISOLATION of portions of the respiratory cha involved in oxidative phosphorylation either b inhibitors that block a portion of the chain or b specific substrates that activate only a portion of th chain show that phosphorylation occurs betwe reduced diphosphopyridine nucleotide and oxygen and cytochrome *c* and oxygen[1,2]. A more exa localization of sites is limited by the availability specific substrates and inhibitors for all parts of th respiratory chain. Our approach is based upon dire spectroscopic observations of the effect of th initiation of oxidative phosphorylation upon th steady state of the components of the respirator chain of intact mitochondria[4]. When respiratio abruptly increases upon addition of adenosi diphosphate to mitochondria supplied with substra and phosphate, we observe a consistent gradation the changes in the steady state along the respirator chain from an oxidation at the dehydrogena portion to a reduction of the oxidase portion[5]. C the basis of these observations, we can identify sit for oxidative phosphorylation in the intact mit chondrial system.

The mitochondria were prepared according to th method of Schneider[6] as modified by Lardy an Wellman[7]. The reactions were studied in the usu 'isotonic' medium. The preparations had values phosphorus/oxygen of about 3 with β-hydrox butyrate as a substrate[8].

For recording the kinetics of spectroscopic chang we use a double-beam differential spectrophotomet with the two monochromators set at wave-lengt differing by the half-width of the absorption band t be measured. Since only the difference of absorptio is measured, the recording is relatively insensitive non-specific changes of light transmission that occ in the mitochondria[9]. The phosphorylative activi and the respiration are monitored simultaneously b a technique based upon the vibrating platinu microelectrode[4,9]. The pairs of wave-lengths th were used in the recording of the components of th

Spectroscopic changes recorded at the wave-lengths indicated with a double-beam spectrophotometer. An upward deflexion indicates a decrease of optical density at 564 mμ (Exp. 348 *b*, *c*)



ig. 2. Difference spectra representing the transitions from erobic mitochondria (state 1) to anaerobic mitochondria (state 5) nd from the fully oxidized state 2 to the antimycin-A inhibited tate. The peaks of the various cytochrome bands are identified n the figure. Rat liver mitochondria, β-hydroxybutyrate as substrate (Exp. 432 d)

spiratory chain are given in Table 1. The observaons reported in this paper are limited to the six mponents that can be separately recorded at these ave-lengths. Other components, not resolved ectroscopically, are omitted from the present distssion because their function in the phosphorylating spiratory chain cannot be incisively evaluated. xamples of such omissions are Slater's factor[10], tochrome $e$[11], mitochrome[12] and vitamin K [13].

*States of the mitochondrial respiratory chain.* The spiratory enzymes exist in a wide variety of states reduction, as illustrated by Fig. 1 for intramitoondrial cytochrome $b$. The mitochondria as diluted the isotonic reaction medium (containing phoshate, but no substrate) are in state 1. Addition of lenosine diphosphate causes a rapid initiation of spiration (see ref. 8, Figs. 1 and 2) and oxidative hosphorylation. Spectroscopically, the double-beam strument records a decrease of optical density at 34 mμ with respect to 575 mμ (note upward deflexion the trace after addition of adenosine diphosphate). his change corresponds to an oxidation of cytorome $b$ (see Table 1). Since only endogenous subrate is present (usually equivalent to 30 μ$M$ oxygen) and excess adenosine diphosphate (900 μ$M$) was added, state 2 is soon reached in which excess adenosine diphosphate is present and negligible respiration occurs (see Table 2). Independent controls show that all the components of the chain are completely oxidized in state 2. Now addition of substrate rapidly reduces cytochrome $b$ (and all the other components to varying degrees) and initiates rapid respiration and phosphorylation (ref. 8, Fig. 1). This is state 3, characterized by high activity. It is terminated when the added adenosine diphosphate is used up and the respiration abruptly decelerates (ref. 8, Fig. 1). Then state 4 is reached, a quiescent condition. A second addition of adenosine diphosphate causes a transition back to state 3. This time state 3 is terminated by exhaustion of the oxygen dissolved in the medium and the anaerobic state (state 5) is soon obtained.

*Difference spectra.* The difference spectrum representing the transition from state 1 to the anaerobic state 5 is given in Fig. 2 (trace 1) and shows absorption bands of cytochromes $a_3$, $a$, $c$ and $b$ as well as flavoprotein and reduced diphosphopyridine nucleotide. Cytochrome $b$, flavoprotein and reduced diphosphopyridine nucleotide absorption bands are more clearly shown when a transition from the fully oxidized state 1 to reduction of these components is obtained by addition of excess antimycin A (Fig. 2, trace 2). By applying to these optical density changes their actual or assumed molecular extinction coefficients (compare ref. 14), we can calculate the concentration of the members of the respiratory chain relative to cytochrome $a$ (Table 3). Observations are included for two types of phosphorylating systems from liver and flight muscle, and for two types of non-phosphorylating systems from liver and heart muscle. The liver mitochondria are distinguished by their large content of diphosphopyridine nucleotide (up to forty times that of cytochrome $a$), which is negligible in the flight muscle sarcosomes and in the non-phosphorylating systems obtained by disruption of mitochondria. The latter systems are relatively deficient in cytochrome $c$, and, in the case of the heart muscle preparation, flavoprotein as well.

The turn-over number of cytochrome $a$ is also computed and ascites tumour cells have the lowest value.

| Rate of oxidation at 25° as 3 μM oxygen is added to anaerobic system (sec.$^{-1}$) | 158 | 120 | 39 | 20 | 13 | — |

has been considered in detail, and a fully developed discussion is beyond the scope of this article. In order to justify the sequence of action of the respiratory enzymes presented in equations 7 and 8, we include in Table 4 a summary of kinetic studies of the oxidation and reduction of the components of the chain as measured by rapid spectrophotometric methods under various conditions: (1) the kinetics of reduction of the components as the oxygen concentration falls to zero due to respiration (given as percentage pigment remaining oxidized); (2) the rate of reduction upon the addition of substrate to state 2; and (3) the rate of oxidation upon adding oxygen to anaerobic mitochondria (states 5–3) as measured in the regenerative flow apparatus[15]. All these kinetic results are consistent with the conclusion that the components react in the sequence in which they are written in equations 7 and 8 below.

*Changes in the steady state caused by the initiation of oxidative phosphorylation.* By comparing the levels of states 1, 3 and 4 with that of state 2 (the fully oxidized state) and by using state 5 as a reference level (see Fig. 1), we have computed the percentage reduction of cytochrome *b* in these three states (see Table 2). By repeating the experiment at pairs of wave-lengths appropriate to the other components (Table 1) we obtain the results shown in Table 2.

The characteristic change in the steady-state levels caused by the initiation of oxidative phosphorylation in a rat liver preparation (state 4–3 transition) is an increase in the reduction of cytochrome *a*, and a decrease in the reduction, or an oxidation, of cytochromes *c* and *b*, flavoprotein and reduced diphosphopyridine nucleotide. These oxidations of components below cytochrome *a* occur in spite of the four- to ten-fold increased respiration when phosphorylation is initiated. The point along the respiratory chain at which the reduction changes to an oxidation is called the cross-over point, and this lies between cytochromes *a* and *c* as illustrated by Table 2. The position of this cross-over point in the respiratory chain depends upon the balance of oxidase and dehydrogenase activities. Either by choosing a liver (from guinea pig) with a different balance of these activities or by adding azide (∼ 100 μM) to the rat liver material, the cross-over poi is moved down the chain to between cytochrom *b* and *c*. At higher azide concentrations, the cros over point lies between reduced diphosphopyridi nucleotide and flavoprotein, no cross-over poi between cytochrome *b* and flavoprotein having be identified.

Specific uncoupling agents such as dinitrophen dibromophenol, and butyl 3 : 5-di-iodo, 4-hydro benzoate, when added to the mitochondria in state cause oxidations and reductions along the respirato chain similar to those caused by adenosine diphc phate.

*Note added in proof.* The same state 4–3 transitio is observed in intact yeast cells when the intr cellular hexokinase activity is used to raise momen arily the intracellular adenosine diphosphate leve The crossover point lies between cytochrom *a* and *c*.

***Action spectrum for adenosine diphosphate.*** So fa we have afforded no proof that the spectroscop changes illustrated by Fig. 1 and measured at oth pairs of wave-lengths given in Table 1 are actually du to the respiratory enzymes named. We have therefo repeated the experiments indicated in Fig. 1 at variety of wave-lengths and have plotted the resultin optical density changes for the state 2–4 and 3- transitions in Fig. 3. Two technical points need t be noted: (1) the spectroscopic data are not co tinuous, but spot checks in the regions omitte indicate that no large absorption bands have be missed; and (2) the optical density changes in t region 580–620 mμ are for a guinea pig and not rat liver preparation; but the curve is plotted accordance with the magnitude of the change for rat liver preparation as given in Table 2.

Remembering that the difference spectra represe the transition from states 3 to 4, the cessation phosphorylation, we observe in support of the resul in Table 2 that there is the appearance of a reduc diphosphopyridine nucleotide band at 340 mμ, reduced cytochrome *b* at 430 mμ and at 564 mμ, an of reduced cytochrome *c* at 550 mμ. The α-band reduced cytochrome *a* at 604 mμ disappears, sin this component is oxidized. The small change oprotein absorption at 465 mμ is caused by uction of the absorbing oxidized form. On iation of oxidative phosphorylation (state 4–3 isition) the converse series of spectroscopic nges is observed.

he absorption bands observed in this transition ely resemble those of the known members of the piratory chain, and do not yet indicate that any ctroscopically distinct forms of the respiratory ymes are required to participate in oxidative sphorylation. Such direct experiments render ikely hypotheses that a special abbreviated piratory chain is required[13] or, in view of the fact t the steady state of many components is affected addition of adenosine diphosphate, that phosrylation occurs at only one point in the respiratory in[16].

*A reaction mechanism.* A mechanism for oxidative sphorylation must satisfy two seemingly incomible requirements of the reactions that occur upon transition from state 4 to 3: an oxidation of the mponents of the respiratory chain below cytoome *a*, together with a four- to ten-fold increase the respiration-rate[8]. The converse effect, the nsition from states 3 to 4 caused by the exhaustion adenosine diphosphate, in many ways resembles effects of an inhibitor of the respiratory chain; example, the effect of antimycin-*A* upon respiran and steady-state levels[14]. In the latter case, ochromes $a_3$, $a$ and $c$ become more oxidized, ereas cytochrome *b* becomes more reduced, the ss-over point for the effect being between cytoromes *c* and *b*. In the presence of azide (see above), same cross-over point is observed when adenosine hosphate is exhausted in the state 3–4 transition, cross-over point identifying the site of action of unknown inhibitory compound. With antimycinthe cross-over point is invariant and the extent of luction of cytochrome *b* as well as the inhibition electron transport are practically complete. With state 3–4 transition, cross-over points are identid at three places along the respiratory chain, and, the case of diphosphopyridine nucleotide, the exnt of reduction is more than 99 per cent and, for a htly coupled preparation, the inition of electron transport exeds 95 per cent[8]. Addition of enosine diphosphate to the inited electron transport chain idly increases respiration[8] by reving such inhibitory compounds m these cross-over points, as idenced by the fact that comnents below cytochrome *a* can come more oxidized in the transin from states 4 to 3. This view at the withdrawal of adenosine phosphate involves an inhibitory ect along the respiratory chain, d that addition of adenosine diosphate reverses this effect, is, of urse, in agreement with hypoeses of those who have approached is problem along rather different es[17,18], but now we are able to dicate the three pairs of respiratory catalysts that are involved in is effect.

Such a current formulation for e reversal-of-inhibition theory is at the oxidation-reduction reaction causes the formation of a high-energy compound with the oxidation product; an example for a particular site of oxidative phosphorylation is:

$$I + c''' + b'' \xrightarrow{k_1} c'' + b''' \sim I \qquad (1)$$

The formation of adenosine triphosphate takes place by the following reactions:

$$b''' \sim I + X \longrightarrow X \sim I + b''' \qquad (2)$$

$$X \sim I + P_i + \text{ADP} \longleftrightarrow X + I + \text{ATP} \qquad (3)$$

In state 4 in the absence of adenosine diphosphate (the amount of *X* or *I* being limited) the $b''' \sim I$ compound, an oxidized, inhibited form of the respiratory enzyme, will accumulate and stop the respiration. There are several experimental data which indicate that the current formulation is inconsistent with our experimental results. First, our results show that the reduced, and not the oxidized, forms of the respiratory enzymes accumulate in the inhibited state 4; for example, diphosphopyridine nucleotide is more than 99 per cent reduced in state 4 (see Table 2). Secondly, mitochondria rendered permeable by hypotonic treatment are found still to contain considerable intramitochondrial reduced pyridine nucleotide which does not elicit rapid respiration unless adenosine diphosphate is added. Nevertheless, addition of a solution of diphosphopyridine nucleotide in the absence of added adenosine diphosphate gives nearly as rapid respiration. Thirdly, mitochondria in state 4 appear to contain an amount of high-energy compound roughly equal to their reduced diphosphopyridine nucleotide content. This compound may react with adenosine diphosphate even in the presence of respiratory inhibitors[19]. These results suggest that reduced diphosphopyridine nucleotide is present in an inhibited form in mitochondria in state 4. While similar experiments have not been carried out with cytochromes *b* and *c*, the analogue computer studies (see below) indicate that the reduced forms of these components are also bound by an inhibitor.

A revised hypothesis that is consistent with our experiments is that the reduced, and not the oxidized,

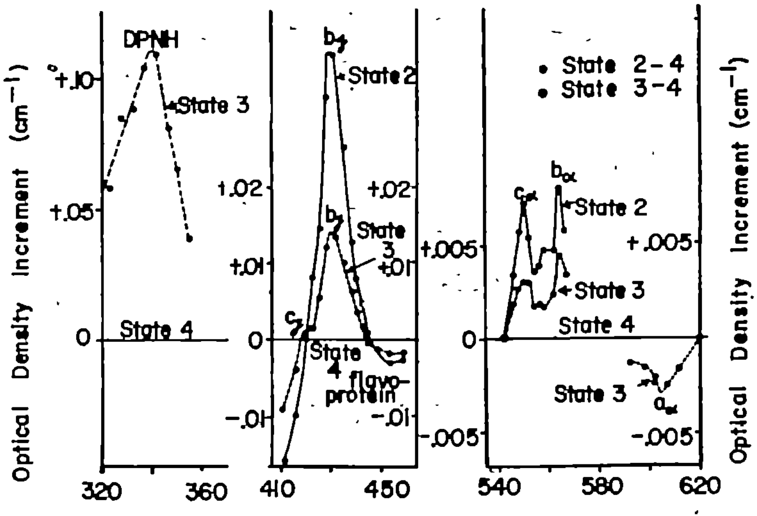

Fig. 3. Action spectrum for adenosine diphosphate, a difference spectrum representing the transition from the active oxidative phosphorylation state (state 3) to the quiescent state 4. The difference spectrum corresponding to the state 2–4 transition is also included. The base-line for both spectra is state 4. (Exp. 359)

fp, rfp, DPN and DPNH represent respectively the oxidized and reduced forms of flavoprotein and diphosphopyridine nucleotide

forms of the respiratory enzymes react with the inhibitor $I$ so as to conserve a part of the free-energy change of the oxidation-reduction reaction.

$$I + c''' + b'' \xrightarrow{k_7} b''' + c'' \sim I \qquad (4)$$

the transfer to $X$ being similar,

$$c'' \sim I + X \rightarrow X \sim I + c'' \qquad (5)$$

(As is described fully elsewhere, the portion of the free energy charge used to form the $\sim I$ compound could have been conserved when cytochrome $c$ was oxidized in the previous reaction cycle by cytochrome $a$, and held over until the reduction of cytochrome $c$ by $b$ as in equation 4, at which time the $\sim I$ compound would be formed.)

Equation 4 is ambiguous and has two interpretations. (1) A non-competitive inhibition of respiration in which the formation of $c' \sim I$ is obligatory and in which $c' \sim I$ cannot be oxidized by cytochrome $a'''$. In this case respiration can proceed only if reaction 5 occurs. (2) A competitive inhibition in which the formation of $c' \sim I$ is not obligatory, and oxidation by cytochrome $a$ can proceed with or without the intermediary reactions leading to phosphorylation. The phosphorus/oxygen (atoms) value of case 1 is fixed; that of case 2 depends upon the relative speeds of formation of the $\sim I$ compound and the competitive oxidation reaction. When the former reaction is rapid compared to the latter, the phosphorus/oxygen (atoms) value for the competitive case rises to that of the non-competitive case.

A transfer reaction initiated by addition of adenosine diphosphate, the state 4–3 transition (cf. equation 5), would cause a definite spectroscopic shift if the spectra of the $\sim I$ compounds differed from those of the uninhibited reduced forms. But our experiments show only absorption bands for the state 4–3 transition (Fig. 3) that can be attributed to known respiratory enzymes. We conclude that no detectable spectral shift occurs in reactions similar to that of equation 5.

Thus the state 4–3 transition releases cytochrome $c'$ with no spectral shift. The observed spectral shift is caused by the rapid oxidation of $c'$ by $a'''$:

$$a''' + c'' \xrightarrow{k_5} c''' + a'' \qquad (6)$$

A similar reasoning applies to the observed oxidations of other components of the chain (cf. Fig. 1 and Table 2).

*Analogue computer studies.* In order to comprehend the effects of the state 4–3 transition more fully, we have represented by means of an analogue computer a reaction sequence involving four of the enzymes and two of the sites for phosphorylation (see Table 5). (The assistance of William Holmes and Joseph Higgins in these computer studies is gratefully acknowledged.) From these and other studies it is possible to make two generalizations concerning steady-state changes following this transition.

(1) For a single phosphorylation site, the co ponent involved will become more oxidized Fig. 1); the components on the oxygen side become more reduced, and those on the substr side more oxidized.

(2) For two adjacent phosphorylations example, at $c$ and $a$), the component nearer oxy may or may not show an oxidation, whereas the nearer the substrate will show an oxidation.

From these two generalizations we obtain very useful cross-over theorem: in the state transition, the component on the oxidation s of the cross-over point from reduction to oxi tion is identified as a site of oxidation ph phorylation. Depending upon the conditions, cy chromes $b$ and $c$ and reduced diphosphopyrid nucleotide have shown this cross-over behavi and are identified as phosphorylation sites. Acco ing to (2), a component on the reduction side the cross-over is not ruled out as a possible s Thus our results do not conflict with those of Lar or Lehninger[2] on phosphorylation between cy chrome $c$ and oxygen.

The series of reactions of Table 5 summari (1) the sequence of spectroscopically detectable co ponents of the oxidative phosphorylation cha (2) the three locations of the reactions which lead the formation of inhibitory high-energy compoun and (3) the transfer reactions by which the inhibit compounds are decomposed by interaction w adenosine diphosphate (these reactions are abb viated forms of equations 3, 4 and 5). The advant of writing the reaction sequence as in Table 5 is th the oxidation and reduction pathways are clea indicated, and that participants in the individ oxidation-reduction reactions are placed over another. Such a sequence includes only those co ponents detectable by these methods and represe only single electron reactions.

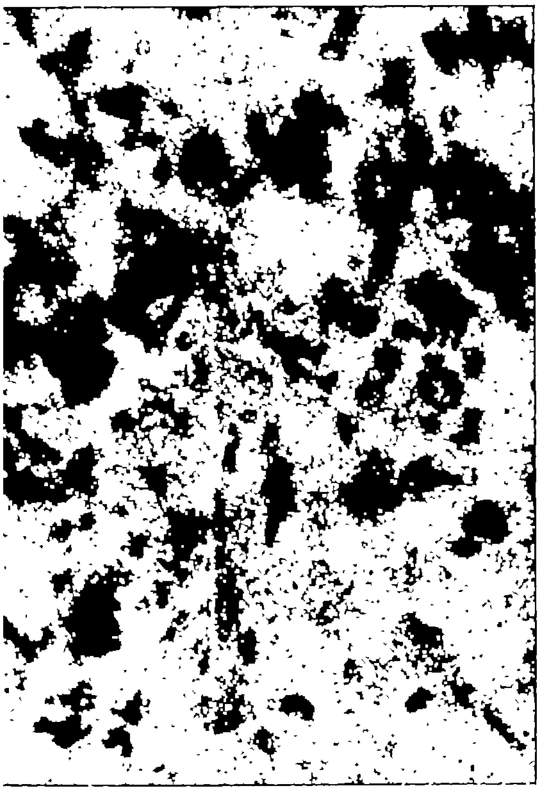
## ntranuclear Changes in the Polyhedrosis of *Tipula paludosa* (Diptera)

HE technique of cutting ultra-thin sections for
tron microscopy has made it possible to follow
behaviour of certain viruses in the cell, and this
particularly true of the nuclear virus diseases of
ects. The present note describes the remarkable
haviour in the nucleus of the polyhedral virus
ich causes a blood disease in the larva of the fly,
*pula paludosa*[1]. Sections through blood cells in
early stages of infection show an apparent con-
sation of the chromatic material in the centre
the nucleus in which the virus rods can be seen
veloping (Fig. 1). Most of the virus rods at this
ge are concentrated in the centre though some
ur scattered throughout the nucleus. The virus
ls are never observed on the outer side of the
clear membrane.

As the disease progresses, what is apparently a
ge thin-walled vesicle develops around individual
us rods which collect in masses on the inner edge
the nuclear membrane. These vesicular masses
apparently held together, probably by a thin
mbrane (Fig. 2). The vesicles are much less dense
n the surrounding medium, and the virus rod in
h vesicle is thinner and more sharply defined than
rods remaining outside. The appearance of the
sicle and the fact that each rod is suspended away
from the sides suggest that there may be a fluid, possibly a protein solution, inside the vesicles. Next, the edge of the mass nearest the nuclear membrane becomes denser, and the vesicles at this point are apparently compressed and much smaller. As crystallization proceeds all the vesicles become greatly reduced in size, possibly because of the osmotic effect of the medium surrounding them, until each vesicle, empty now of fluid and closely pressed around the virus rod, eventually forms the capsule in which each virus rod in the polyhedral crystal is enclosed. It may be that fluid forced out of the vesicles is used in the crystal formation.



ig. 1. Thin section through part of the centre of a diseased nucleus, showing the developing virus rods. × 50,000

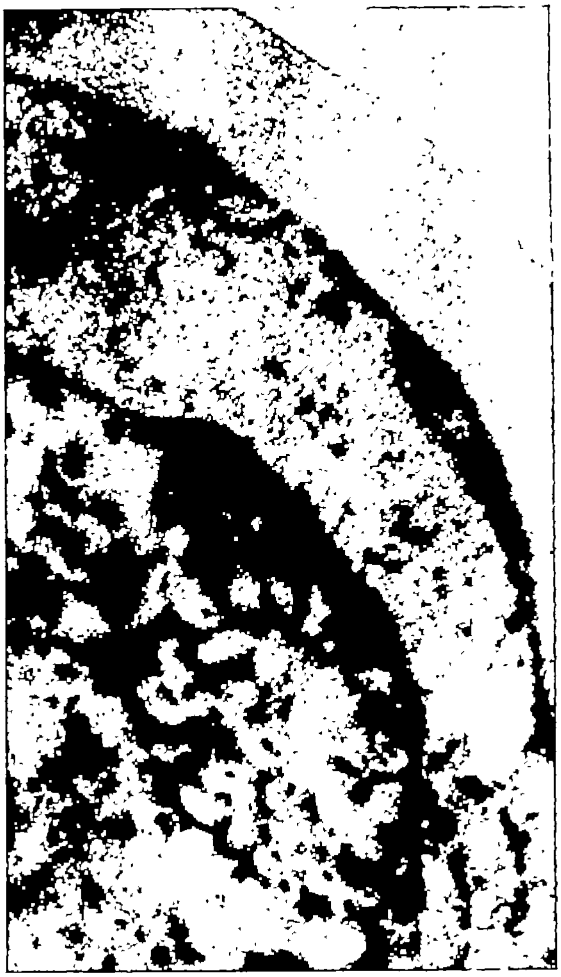


Fig. 2. Segment of a diseased blood cell, showing the mass of vesicles against the inner edge of the nuclear membrane. × 25,000

All these changes take place inside the nucleus; but the final position of the completed crystal is outside the nucleus with its inner edge along the nuclear membrane. Apparently as the crystal forms it is forced out of the nucleus until it reaches that position.

The accompanying electron micrographs were taken by S. Vernon-Smith.

# Xanthomycin A

WHILE studying the antibacterial products of a species of *Streptomyces* (N.C.I.B. 8697) sent by Dr. R. Green from Malaya, we have isolated an orange-red coloured basic substance which is very active against a variety of bacteria and is highly toxic to mice. The antibiotic was extracted from the culture fluid into chloroform, at $p$H 6, and re-extracted into water at $p$H 2, or extracted into trichloroethylene, at $p$H 8·5, and re-extracted into water at $p$H 3·5. It was purified by counter-current distribution in a solvent system consisting of trichloroethylene and 0·1 $M$ sodium citrate buffer, $p$H 5·95. In this system its partition coefficient, $K$ (= concentration in trichloroethylene/concentration in water), was 0·98. The purified product yielded a crystalline hydrochloride, reineckate and picrate. The behaviour of this antibiotic suggests that it is identical with, or very closely related to, xanthomycin *A*—a substance which has been isolated from species of *Streptomyces*[1], and stated to have quinonoid properties[2]. We wish to record, however, that it is a stronger base than xanthomycin *A* has been reported to be and that it yields two simple bases on hydrolysis which have not been described as degradation products of xanthomycin *A*.

A number of properties of the antibiotic from the Malayan *Streptomyces* were similar to (and in some cases virtually indistinguishable from) those reported for xanthomycin *A*. The hydrochloride of the antibiotic ($[\alpha]^{20}_{D}$ + 100, in water) had an equivalent weight of approximately 540 and gave analytical data which were not inconsistent with the molecular formula $C_{23}H_{29-31}N_3O_7,2HCl$. It showed an ultra-violet absorption spectrum with a maximum at 265 mμ ($E$(1 per cent, 1 cm.) 180) and an infra-red spectrum that was almost identical with one published by Rao and Peterson[2]. The partition coefficient of the antibiotic in the system chloroform–0·1 $M$ sodium citrate buffer, $p$H 4·2, was close to unity. The free base, obtained from an aqueous solution at $p$H 6 by extraction with chloroform, yielded a product on evaporation of the solvent which showed absorption maxima at 288 and 455 mμ. On paper chromatograms run with $n$-butanol containing 1 per cent by volume of normal hydrochloric acid, the antibiotic behaved as though it could exist in two forms, with $R_F$ values of 0 and 1·0 respectively, which were interconvertible.

A concentration of 0·002 μgm./ml. of the antibiotic inhibited the growth of *Staph. aureus* (N.C.T.C. 6571) in meat broth, and a dose of 30 μgm., given intravenously, proved lethal to a 20-gm. mouse within three days (Florey, H. W., unpublished experiments). These values appear to be of the same order as the corresponding values reported for xanthomycin *A*.

Xanthomycin *A* has been reported to contain two weakly basic groups with $pK$ values of 2·0 and 4·5. Electrometric titration revealed that the antibiotic from the Malayan *Streptomyces* contains basic groups with $pK$ values of 3·0 and 7·3 respectively. Below $p$H 9 the titration is reversible. Above $p$H 11 the antibiotic undergoes a rapid irreversible change, resulting in loss of activity, the virtual disappearance of the group with $pK$ 7·3, and the appearance of groups with $pK$ values of about 9·7 and 4·7 respectively. The presence of a group with $pK$ 7·3 in the antibiotic is consistent with the fact that it migrates as a base during ionophoresis on paper in collidine acetate buffer at $p$H 7·0[3], and that its partition coefficient in a trichloroethylene–wa system increases rapidly as the $p$H of the aque phase is raised from 6 to 8. The fact that it is larg extracted by chloroform, like xanthomycin *A*, fr an aqueous solution at $p$H 6, can be attributed the very high partition coefficient of the free bas favour of the chloroform phase.

The antibiotic gives only a poor ninhydrin reacti but yields two ninhydrin-positive bases on treatm with 6 $N$ hydrochloric acid at 105° for twenty hou The first base is highly volatile and is indistingui able from methylamine when subjected to io phoresis on paper, at $p$H 7·0, or to chromatogra on paper in butanol–acetic acid[4]. The second b is less volatile and is oxidized by periodate to yi ammonia. It is easily recovered from hydrolysa together with the first, by azeotropic distillat with toluene[5]. When subjected to ionophoresis paper at $p$H 7, or to chromatography on pap developed with butanol–acetic acid or butan pyridine–water[6], it is indistinguishable from ethar amine. Quantitative studies[7] have shown that nea one mole of the first base and two moles of second are liberated from one mole of the antibio

Hydrogenation of the antibiotic in the presence palladium on charcoal resulted in the uptake of nea three moles of hydrogen. No ethanolamine v detected after hydrolysis of the product of hyd genation. This suggests that the ethanolamine not joined to the rest of the molecule by eithe normal amide or ester linkage alone, or by both ty of linkage. The infra-red spectrum of the antibic shows no band corresponding to the CO of a norr ester grouping, but bands at 6·03μ, 8·70μ, 8· and 9·13μ. It is of interest that bands in the reg of 8·70μ, 8·98μ and 9·13μ have been reported be shown by simple oxazolidines and a band in t region of 6·03μ by the corresponding Schiff's bas

# Effects of Adenosine Triphosphate and Metals upon an Electron Transport System in Mitochondria

IN the course of studies on oxidative phosphoryl tion coupled with the succinoxidase system of r liver mitochondria, it was found that adenosi triphosphate, alone and with certain metals, si nificantly accelerated reduction of triphenyltet zolium chloride to triphenylformazan.

Mitochondria were isolated from rat livers homogenization in 8·5 per cent sucrose and coagul tion with 0·15 $M$ potassium chloride[1]. The reactio

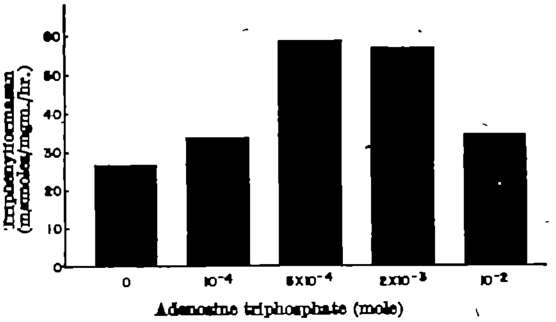

Fig. 1. Effect of varying amounts of adenosine triphosphate on production of triphenylformazan by mitochondria. The reaction mixture totalled 3·0 ml., containing 50 μmoles of potassium succinate, 400 μmoles tris (hydroxymethyl) amino-methane buffer pH 7·4, 1 μmole of triphenyltetrazolium chloride, 0·2 ml. of mitochondria in 0·15 *M* potassium chloride

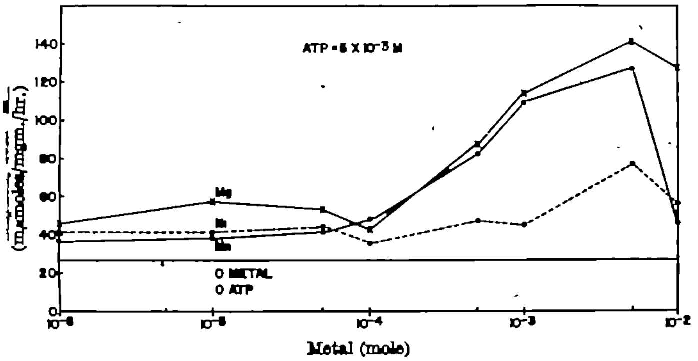

Fig. 2. Effect of varying amount of magnesium, manganese or nickel with a constant amount of adenosine triphosphate on the production of triphenylformazan by mitochondria

roceeded aerobically for sixty minutes at 25° C. ithout shaking. The protein was precipitated by he addition of 3 ml. of acetone to terminate the eaction and removed by centrifugation; simult-neously, the triphenylformazan was extracted and s concentration was determined at 480 mμ.

The addition of adenosine triphosphate in varying uantities to the reaction mixture produced a marked icrease in the reduction of triphenyltetrazolium hloride; similar concentrations of adenosine monohosphate or pyrophosphate had no effects (see Fig. 1). ts effect was maximal at concentrations between 0·5 and 2 × $10^{-3}$ *M* and statistically significant in a series of experiments. Since the effect of adenosine triphosphate in biochemical systems has been shown to be dependent upon the presence of magnesium or manganese[1], and since mitochondria contain significant amounts of these and other metallic elements (unpublished work with R. E. Thiers), the effect of the addition of a variety of metals with varying amounts of adenosine triphosphate was studied: aluminium, barium, beryllium, calcium, chromium, cobalt, copper, iron, magnesium, manganese, molybdenum, nickel, strontium, vanadium and zinc. The effects of the addition of varying amounts of magnesium, manganese or nickel with a fixed amount of adenosine triphosphate is shown in Fig. 2. Fig. 3 shows similar results obtained when varying amounts of adenosine triphosphate were added together with fixed amounts of magnesium or manganese. Significantly, maximal activation of the production of triphenylformazan occurred when metal and adenosine triphosphate concentrations were equal.

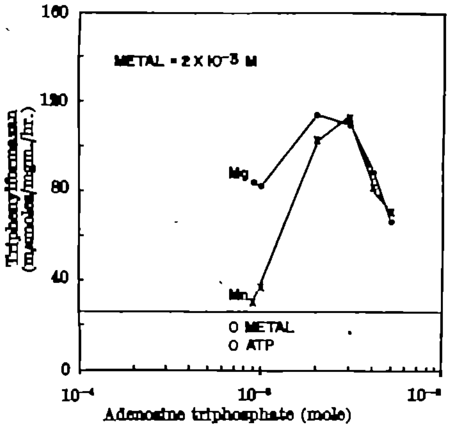

Fig. 3. Effect of varying amounts of adenosine triphosphate with a constant amount of magnesium or manganese on the production of triphenylformazan by mitochondria

Studies on the interaction with other elements showed that calcium, barium, strontium and chromium neither produced additional activation nor interfered with the action of adenosine triphosphate in activating this reduction mechanism. Beryllium, aluminium, zinc, copper, iron, vanadium and molybdenum not only had no stimulating effect but also abolished the stimulation due to adenosine triphosphate itself.

The enhancement of the stimulatory effect of adenosine triphosphate upon reduction of triphenyltetrazolium chloride when magnesium, manganese or nickel were added in equimolar quantities suggests as a working hypothesis that the adenosine triphosphate alone acts in conjunction with the metals of mitochondria. The levels of concentrations of magnesium and manganese in mitochondria support such a hypothesis. The relationship of metal–adenosine triphosphate complexes to electron transport is now under investigation for its implications in the mechanism of oxidative phosphorylation. A similar suggestion, based upon a different experimental approach, has been advanced recently[3]; our attempts to complement this hypothesis by the repetition of Lindberg and Ernster's experiments have failed so far. The substance of this communication will be published more fully elsewhere.

These studies were aided by a contract between the Office of Naval Research, Department of the Navy, and Harvard University, NR5ori-07660, and grants from the National Institutes of Health and the United Fruit Co.

## Distribution of Free Amino-Acids in Embryos of *Xenopus laevis*

RECENT investigations[1,2] have shown that some of the free amino-acids in amphibian embryos change in concentration during early development. These changes are of interest because they may be related to the synthesis of new, specific proteins[3]. It has been shown that halved embryos of *Rana pipiens* and *Hyla regilla* allowed to develop in a medium containing radioactive glycine or methionine will incorporate these amino-acids directly into protein, and that the rate of incorporation is particularly high in dorsal halves of gastrulæ and neurulæ, which are known to synthesize protein more rapidly than other parts of the embryo[4,5].

The most complete investigation so far published[2] on free amino-acids in amphibia was carried out on whole *Rana pipiens* embryos. These contain free aspartic acid, glutamic acid, glycine, histidine, threonine, arginine, tryptophan and valine. Aspartic acid, glycine, histidine and threonine are present in high concentration at the beginning of development, and their concentration falls sharply during cleavage, rising afterwards to a maximum at the neurula stage. Arginine, tryptophan and valine are present in very low concentration at first, and their concentration rises steadily during development, to reach a maximum in the neurula. No data were given for separate dorsal and ventral regions of the embryo.

Work which is now in progress on embryos of *Xenopus laevis* shows that the whole embryos, like those of *R. pipiens*, contain free aspartic acid, glutamic acid, glycine, arginine and valine; but that, in addition, free glutamine, α-alanine, β-alanine, leucine and cystine are present (Fig. 1). Histidine, threonine and tryptophan, on the other hand, cannot be detected. Aspartic acid and glutamic acid are present in highest concentration, and these show a significant decrease between morula and early gastrula stages. Glutamine, also present in fairly high concentration, shows a significant decrease between late neurula and early tailbud stages. The concentration of leucine increases significantly between early and late gastrula stages, with a further increase at the tailb stage.

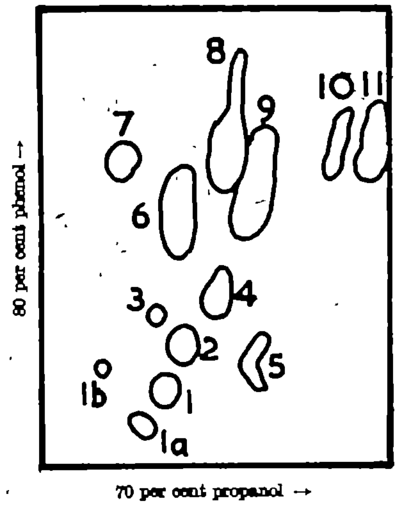

Fig. 1. Map showing the positions taken up on chromatograms by the eleven free amino-acids identified in *Xenopus laevis* embryos. (1) Aspartic acid; (1*a*, *b*) ? glutathione; (2) glutamic acid; (3) ? cysteine; (4) glycine; (5) cystine; (6) glutamine; (7) arginine; (8) β-alanine; (9) α-alanine; (10) valine; (11) leucine

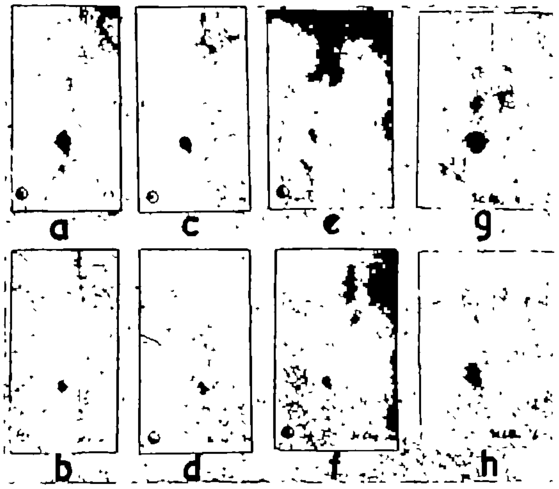

Fig. 2 Chromatograms of the free amino-acids extracted from 10-mgm. samples (frozen-dried weight) of tissue from different regions of the embryo. (*a*) Animal half of blastula; (*b*) vegetal half of blastula; (*c*) dorsal lip of early gastrula; (*d*) remainder of early gastrula after excision of dorsal lip; (*e*) dorsal half of late gastrula; (*f*) ventral half of late gastrula; (*g*) dorsal half of neurula; (*h*) ventral half of neurula (compare with Fig. 1)

In addition to the work on whole embryos, t free amino-acid content of dorsal and ventral regio of blastulæ, gastrulæ and neurulæ have been analys separately. In the blastula, there is a higher co centration of total free amino-acid (γ/mgm. froze dried tissue) in the animal half than in the veget half: this difference is particularly marked f aspartic acid. In the early gastrula, the concentrati of total free amino-acid is higher in the dorsal l than in the rest of the embryo. Dorsal and ventr halves of the late gastrula, on the other hand, ( not differ significantly in their free amino-acid co tent. By the late neurula stage the difference betwe dorsal and ventral halves has reappeared. In pa ticular, aspartic acid, glutamic acid and glutami are present in significantly higher concentration the dorsal half. Chromatographs of the free amin acids in these half-embryos are compared in Fig.

Special precautions were taken throughout obtain clear, consistent chromatographic results a to avoid all possibility of autolysis in the embryon tissue. The procedure was as follows: since sali caused streaking of the chromatograms, samples embryos were collected in distilled water. T embryos that were to be analysed whole were ke alive in this medium by not removing the jelly fro them. (Test chromatograms of jelly alone had show that it contained no detectable amino-acid.) Embry that were later to be halved had, however, to demembranated first. This was done as quickly possible, on groups of not more than twelve embry which were then frozen immediately on an ice/s bath at − 10° C. Batches of embryos prepared one of the above methods were stored in the de freeze and then frozen-dried. The frozen-dri demembranated embryos could then be dissected leisure, at room temperature, without any danger autolysis. The tissues were ground up in a morte and the free amino-acids obtained from them by fo successive extractions with 80 per cent ethanol, an ice-bath. (Previous trials had shown that a fif extraction with ethanol did not remove any furth ino-acid.) The combined extracts were evaporated dryness at 60° C. and the residue was redissolved the minimum 80 per cent ethanol for transfer to in. squares of Whatman No. 1 filter paper for omatography. Chromatograms were run two-nensionally, using as the first solvent 80 per cent v) phenol with 3 c.c. of 30 per cent aqueous monia added for every 500 gm. phenol. The ond solvent was 70 per cent propanol. The omatograms were sprayed with 0·5 per cent hydrin in absolute ethanol, and the colour de-oped at 65° C. for twenty minutes. The quantities individual amino-acids present were estimated by olorimetric method[6].

sing this technique, it is possible to carry out lyses of the free amino-acids not only in whole bryos but also in different regions representing ferent tissue primordia. Any regional differences free amino-acid content which might be related the early synthesis of tissue-specific proteins can this way be detected. The results already quoted icate that at least dorsoventral regional differences exist: further work on more precisely defined ts of neurulæ, tailbud stages and early larvæ is in progress.

## Metabolism of Triaryl Phosphates in Rodents

ONSIDERABLE interest is attached to the meta-ism of the compound tri-*o*-cresyl phosphate, which been shown to inhibit various esterases *in vivo* which is capable of producing demyelination and alysis in certain species of animals[1]. Pure tri-*o*-syl phosphate exhibits little inhibitory activity inst esterases *in vitro*[2,3] and the compound pears to be converted into an active inhibitor in animal; this conversion can also be effected by ubation with liver slices *in vitro*[3].

t had been shown previously by Gross and sse[4] that, two hours after intravenous injection of -*o*-cresyl phosphate into rabbits, an amount of sol ester equivalent to 70 per cent of the ad-nistered compound can be recovered from the estinal tract and an amount equivalent to 50 per t from the liver of the animal. The amounts of sol ester present in other tissues were too small be determined, although a large proportion of the sol ester is later excreted in the urine[4]. In our eriments we had found an active esterase in-itor in the urine of rats and rabbits after intra-itoneal injection of tri-*o*-cresyl phosphate[5]. This ding suggested that the cresol esters measured by oss and Grosse might in fact be reactive derivatives tri-*o*-cresyl phosphate. We proceeded, therefore, examine the tissues of the rats for esterase inhibit-activity after intraperitoneal injection of tri-*o*-syl phosphate, this compound being readily orbed from the peritoneal cavity[4].

The tissues were homogenized with four volumes of water, the proteins precipitated by the addition of three volumes of ethanol to the homogenate, and various amounts of the supernatant fluid were incubated with a 1 per cent solution of human serum at 37·5° and pH 7·4 for 30 min. Under these conditions, extracts of tissues from normal animals fail to cause any significant inhibition of the pseudocholinesterase of human serum. However, the extracts obtained from the tissues sixteen hours after intraperitoneal injection of 1 ml. tri-*o*-cresyl phosphate per kgm. into adult male rats proved to be strongly inhibitory. The pseudocholinesterase of human serum was 50 per cent inhibited by the addition of the extract from 0·1 mgm. fresh weight of liver or 0·03 mgm. of intestine to 1 ml. of the incubation mixture. No significant inhibition was observed with extracts of brain, while the remaining tissues tested (blood, kidney, pancreas, spleen, lung, testis, salivary gland, Harderian gland and the remaining carcass) all contained small amounts of the inhibitor, 50 per cent inhibition of the pseudocholinesterase being obtained when the extract from 3–4 mgm. of fresh tissue was added to 1 ml. of the incubation mixture. The total inhibitory activity present in the tissue extracts was 3–6,000 times greater than the total inhibitory activity present in the tri-*o*-cresyl phosphate which had been injected; that is, the derivative formed in the animal must be at least six thousand times more active than the original compound as an inhibitor of pseudocholinesterase. Approximately 80 per cent of the total esterase inhibitor was located in the intestinal tract, while 12 per cent was recovered from the liver and 8 per cent from the remainder of the body. These values agree fairly well with the determinations of cresol ester in rabbits reported by Gross and Grosse[4].

The concentration of inhibitor in the liver appears to reach a maximum within 30 min. after the injection of tri-*o*-cresyl phosphate, while the concentration in the intestine increases slowly to reach a maximum after several hours. The hypothesis that tri-*o*-cresyl phosphate is converted into an active inhibitor in the liver, excreted in the bile and re-absorbed in the intestine was confirmed by the fact that the bile of rabbits and intestinal contents from rats and rabbits contain very high concentrations of the reactive inhibitor after injection of tri-*o*-cresyl phosphate. Appreciable amounts of the inhibitor can still be recovered from the liver and intestine 7–10 days after the tri-*o*-cresyl phosphate was administered.

The structure of the reactive derivative of tri-*o*-cresyl phosphate is not known. However, a similar inhibitor of serum pseudocholinesterase can be recovered from the liver and intestine after the administration of triphenyl phosphate. Moreover, Bloch has reported that the esterases of the rabbit can be inhibited *in vivo* by the administration of tri-*o*-chlorophenyl phosphate as well as by tri-*o*-cresyl phosphate[6]. Thus it seems probable that the primary alteration in the structure of the triaryl phosphates leading to the formation of reactive inhibitors *in vivo* is a substitution on one or more of the phenyl rings. By analogy with the results obtained with other aromatic derivatives[7], we would expect that a hydroxyl group is introduced into the *para* position and afterwards converted to a sulphate or glucuronide.

Further examination of the urine and liver preparations obtained in the above experiments has revealed the presence of more than one inhibitor.

The major portion of the inhibitory activity is due to a compound which is soluble in ether and other organic solvents, and unstable in aqueous solution. A small part of the total inhibitory activity is due to a compound which is poorly soluble in ether, and stable in aqueous solution at neutral and at acid pH. It is possible that other derivatives may be formed in small amounts[7]. Further experiments on the separation of these compounds are being carried out.

## A New Difference between Live and Dead Spermatozoa

When semen is diluted with a solution of formaldehyde under certain standard conditions of pH, temperature and osmotic pressure, dead spermatozoa are agglutinated but living ones are not. This difference between live and dead spermatozoa has been investigated in 103 ejaculates from seven bulls at a commercial insemination centre. Samples from a hundred of these ejaculates were used for insemination, three ejaculates being unsuitable for insemination because of low sperm motility.

The percentage of dead spermatozoa in duplicate samples of each ejaculate was estimated in smears stained with nigrosin-eosin[1]. The staining solution (pH 7·2; Δ, − 0·54° C. ± 0·02° C.) was used at 37° C. Details of the composition of this new solution and of the buffered formal-saline used here will be published elsewhere. Duplicate samples of each ejaculate were fixed in a buffered isotonic solution of sodium chloride (pH 7·0; Δ, − 0·53° C.) with added formaldehyde (5 per cent formaldehyde), by adding one drop of semen at 37° C. to each of two tubes containing 3 ml. fixative also at 37° C. After fifteen minutes incubation at 37° C., the samples were allowed to cool to room temperature.

Measurements of the percentage of dead (eosinophil) spermatozoa and of the degree of agglutination were made after a variable period (up to two weeks), following treatment of the sample. The number of dead spermatozoa in a total of a hundred was counted on each of two slides. The degree of agglutination was scored on a unit scale of 1 (minimal agglutination) to 4 (maximal agglutination). The samples were shaken and scored by visual assessment of agglutination using transmitted light. The percentage dead and the agglutination score were estimated independently by different observers.

The relationship between percentage dead spermatozoa and agglutination score was examined by regression analysis. The mean percentage dead spermatozoa was used as one variable, and the co bined agglutination scores for each sample pair the second variable. The analysis was made Dr. R. C. Campbell, Agricultural Research Cou Unit of Reproductive Physiology and Biochemist Cambridge.

A highly significant relationship ($p < 0·001$) found between percentage dead spermatozoa agglutination score. The mean percentage of d spermatozoa for all samples was 16·7 (range 3·5–65· the mean agglutination score for all samples was (range 2–8). The mean percentages of dead spe atozoa in the three ejaculates discarded as unfit insemination were 65·0, 40·0 and 39·5; the co bined agglutination scores were 8, 6 and 6.

This difference between living and dead cells d not seem to have been noted before and it may th fore be of some fundamental interest; but, at moment, we are more concerned with the follow practical implications. In 103 samples of bull se which, with three exceptions, were judged to suitable for insemination, there was a pronoun relationship between the proportion of dead spe atozoa and the degree of agglutination after treatm of the semen with formaldehyde. A relationshi known to exist between the fertilizing capacity bull semen and its content of dead spermatozo the agglutinability of spermatozoa by formaldeh may therefore be a simple and useful criterion of fertilizing capacity of bull semen.

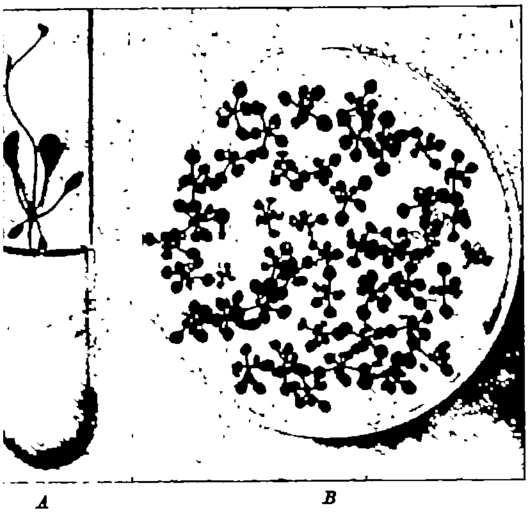
## Biochemical Mutations in the Crucifer *Arabidopsis thaliana* (L.) Heynh.

The photosynthetic flowering plants possess greater capacity for synthesis of crystalloids than other group of organisms. Their complete exogen requirements for growth consist of only fourt elements and the two compounds carbon dioxide water. No intact flowering plant, with the except of those lacking chlorophyll, has been shown require any organic compound apart, of course, fr carbon dioxide. I have now attempted to exam plant biosynthesis by the 'mutational block' meth which has been of great success in the analysis metabolism in haploid micro-organisms.

Selection of mutants deficient in essential synthe can only be carried out satisfactorily under ase conditions, so a necessary prerequisite is an adequ method for the sterile culture of higher plants. this respect the suitability of the experimental pl



1. *Arabidopsis thaliana.* *A*: normal plants, 14 days old, wing aseptically on 5 ml. mineral agar in a 16 mm. × 160 mm. t-tube; nearly full size. *B*: forty-five plants, 13 days old, wing aseptically on cellulose pulp in a Petri dish of 9-cm. diameter; about half-size

ritical, and a search was made for small rapidly wing plants with certain other necessary attributes. *rabidopsis thaliana* (L.) Heynh.[1], a small crucifer 1 a short life-cycle (28 days), a low chromosome iber ($n = 5$), and a high seed output, fitted the uirements reasonably well. In culture, the plants w well on 5 ml. of medium in ordinary test-tubes . flowered 13–14 days after germination. The lium, solidified with 0·6 per cent agar, contained y the minerals of Knop solution and chelated trace nents. Seeds were sterilized in hydrogen peroxide l ethanol (1 : 1), a method recommended to me by J. Harris, and transferred to the agar medium h a platinum loop. After a 24-hr. cold treatment ensure uniform germination, the cultures were ed in a growth chamber maintained at 25° C. and ut 800 ft.-candles light intensity.

'lants may be grown on a large scale in Petri dishes taining pure cellulose and mineral nutrients. itamination was avoided by packing the space ut the lid with cotton-wool pretreated with yl-pyridinium chloride. The inner surface of the may be treated with 'anti-dim' to prevent water densing in large drops and reducing the available t. When the plants entered the reproductive se, the Petri dish lid was removed to allow igation of the flower stalk, flowering and seed-ing. Fifty plants may be grown to maturity in h Petri dish.

'he required mutations were induced by X-irradia-1[2] (6,000 r., 130 kV.) of seeds, and isolated by wing the segregating ($X_2$) generations on sterile, mically defined medium. From 110 $X_2$ families, nty-seven mutants have been isolated, nine of se being lethals.

)ne mutation, inherited as a simple recessive, ders the plant incapable of synthesizing thiamine. tant plants have mottled cotyledons, and the sequent leaves are white or have chlorophyll only the tips. The block in synthesis, however, is not olute, for after a lag in growth, which increases duration as the temperature is raised, the plants ome green again and resume growth. All plants at temperatures above 27° C.; but at 20° C. only 10 per cent show any deficiency symptoms. Irrespective of the temperature, all grow normally with 1 μgm. of thiamine per plant. There is some evidence suggesting that the coupling of derivatives of pyrimidine and thiazole to form the thiamine molecule is blocked.

Another recessive lethal mutant, although green, has cotyledons which show early degeneration and the plant dies at the two-leaf stage. When supplied with coconut milk, this mutant will grow slowly and eventually flower. Its specific requirements have not yet been identified.

Three of the lethal mutations prevent the formation of plastids from proplastids. Their effects are apparently not expressed solely as an inactivation of the photosynthetic mechanism, for the plants show no growth response to added sucrose. The formation of chlorophyll is prevented in yet another mutant; but deficient plants will grow slowly and form flowers if sucrose is supplied in the medium. The three remaining lethal mutants have green cotyledons but produce only one pair of very small pale-green leaves. They resemble phenocopies obtained with specific amino-acid antagonists; but no supplement has been found that will improve their growth.

It is to be expected that many mutations blocking metabolism will be eliminated by the sieve of seed development. Thus mutations affecting respiratory processes and the formation of non-diffusible substances necessary for embryo growth will probably not be detected in the $X_2$ generation. Biochemical genetics in flowering plants is therefore likely to be a more restricted field than its counterpart in the micro-organisms.

A detailed description of these experiments will be published elsewhere. I thank Prof. D. G. Catcheside, in whose laboratory this work was carried out, for helpful criticism and advice; Prof. F. Laibach, of Frankfurt-am-Main, for seeds of *Arabidopsis thaliana* and for generous advice; and the Commonwealth Scientific and Industrial Research Organization for the award of a studentship.

## A New Technique for the Study of Chromosomes of Palms

THE study of the chromosomes of palms has always been considered very difficult, as is clearly evidenced by the lack of data on a large number of genera[1]. Even where the number of chromosomes has been recorded, the details of the structure are unknown.

In recent years, the use of a number of pre-treatment chemicals[2,3] has solved to a great extent the problem of karyotype study. But all these are of limited application, appropriate only to certain groups of plant; none of these methods when tried on palms proved to be of any use.

In the study of the cytology of tropical palms which has been undertaken in this laboratory, a number of alkaloids were tested for the fixation of their chromosomes. With one of the alkaloids, namely, aesculine (a derivative of *Aesculus hippocastanum*), excellent results were obtained. Its application in chromosome analysis appears to have solved this long-standing difficulty.

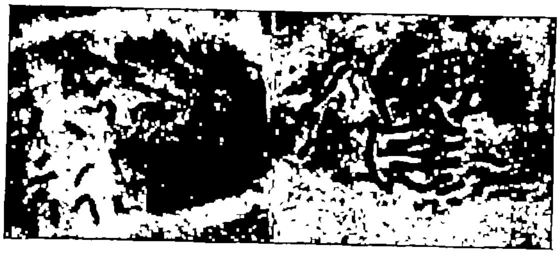

Fig. 1. Somatic metaphase plates of (1) *Oreodoxa regia* H.B. and K., and (2) *Rhapis flabelliformis*, L'Hérit., showing 36 and 34 chromosomes respectively following æsculine treatment

Freshly cut root-tips were treated for different intervals of time at various temperatures, prior to treatment for a few seconds in a mixture of 2 per cent aceto-orcein and *N* hydrochloric acid (9 : 1). Then the tips were smeared in 1 per cent aceto-orcein. Excellent results could be obtained if the tips were treated in a saturated solution of æsculine in water for twenty-four hours, the first two hours being at a temperature of 2°–4° C. and the remainder of the period at 12°–18° C. After treatment, the tips were heated in the dye-acid mixture mentioned above and stained in orcein in the usual way. Application of uniform and sufficient pressure during smearing was very necessary for good results.

The chromosomes come out well scattered with constriction regions distinctly clarified (Fig. 1). So far, about thirty species of palms known to be difficult of analysis have been tried, and the technique proves to be equally effective in all.

The effect of the treatment appears to be principally a change in the plasma viscosity, as suggested by Stalfelt in the case of oxyquinoline[3]. Further, we believe, from the results obtained with a number of chemicals[4], that æsculine to some extent brings about a coagulation of protein—a process which is finally completed by treatment in the dye-acid mixture. Fixation is thus to be attributed to both these steps.

# Hypomagnesæmia in Dairy Cattle and its Possible Relationship to Ruminal Ammonia Production

THE highest incidence of hypomagnesæmia in dairy cattle occurs in the first few weeks of the spring grazing which follows the winter stall-feeding period. Some factors which influence its incidence at this time and methods for its control have been studied at this Institute for several years[1]. Recently, we have investigated the changes in blood composition, rumen fermentation and mineral metabolism caused by the transfer to grazing or the feeding of cut spring grass in the stall, and several observations have ar
which suggest a possible mechanism for the
duction of hypomagnesæmia.

The daily intake of magnesium by a grazing
receiving no other food or mineral supplemen
20–30 gm., which is comparable with the int
during the stall-feeding period, and it is gener
considered that hypomagnesæmia does not arise f
an inadequate intake of magnesium. We have fo
that the excretion of magnesium in the urine of
cow is markedly and rapidly reduced with the cha
to spring grass. To quote two examples, the d
urinary excretion of magnesium of one cow fell wit
the first twenty-four hours from 3–4 gm. to 1·5
and then gradually to 0·2 gm. at the end of ei
days; while in another, the initial daily excret
of 1·5 gm. fell to 0·1 gm. over the same per
There was a concomitant fall in blood serum m
nesium level in both animals from more than 2 mg
100 ml. to about 1 mgm./100 ml. If such a fal
the urinary excretion of magnesium reflects a redu
intestinal absorption, as observed by McCance
Widdowson[2] in humans, it would indicate that
ruminants the magnesium of spring grass has
unusually low availability. Garner[3] has shown th
*in vitro*, the action of rumen micro-organisms
gastric juice releases the magnesium of grass, so t
it would appear that during the early grazing per
there is some alimentary disturbance which modi
the availability or absorption of magnesium.

Among the observations made in our rumen stud
a highly significant one, we feel, has been a rise
the ammonia content of rumen liquor, on the trans
to grass feeding, to a continuously high level of
60 mgm./100 ml. In contrast, under winter st
feeding conditions, a general level of 10–20 mgm./
ml. was found, with peak values of 30 mgm./100
for short periods after feeding. That ammonia p
duction on grass was abnormally high was a
reflected by the presence of ammonia in jugu
blood, up to 0·3 mgm./100 ml. being observ
indicating that the capacity of the liver for the c
version of portal blood ammonia to urea had be
exceeded.

In view of these observations, an attempt was ma
to influence the absorption of magnesium in cat
receiving a hay and concentrate ration by the ad
tion to the rumen, via a fistula, of ammoni
acetate and ammonium carbonate. The da
addition of 1,250 gm. or more of these salts per c
for a period of four days produced ruminal ammo
levels comparable with those observed on grass, a
similarly reduced the urinary excretion of magnesiu
Smaller additions had no effect. This reduction
magnesium excretion was accompanied by a fall
the serum magnesium from 2·5 to 2·0 mgm./100

In view of these observations, we feel justified
suggesting that hypomagnesæmia of cows on gra
and particularly during the early spring, arises fr
an inadequate absorption of magnesium and is pr
ably associated with high ruminal ammonia p
duction. The mechanism is not understood;
it is feasible that ammonia may pass in quant
from the rumen to the small intestine, where an int
action between ammonia and magnesium absorpti
could take place.

The marked difference in swards in their abil
to produce hypomagnesæmia, and the spontane
recovery in serum magnesium levels of cattle as t
grass matures and the nitrogen content falls, mig
be explained, at least in part, by the critical nat

the ruminal ammonia-level. The severity of hypo-gnesaemia in dairy cattle grazing a given sward uld be determined by the animals' individual serves of magnesium at the end of the winter feeding riod, and by the level of their daily requirement. This series of studies, involving field-trials, balance periments and studies of rumen digestion, is being ntinued.

We gratefully acknowledge the collaboration of our lleagues at this Institute in this work.

## ar Formation in Timothy Grass (*Phleum pratense*) following Vernalization and Short-day Treatments

In many perennial grasses of temperate regions, posure to low temperature has proved to be a cessary condition for the attainment of the reproctive phase. After vernalization, flowering may cur directly in response to long-day conditions in me grasses[1], or after initial treatment with short ys followed by transfer to long photoperiods in hers[2,3]. The precise requirements of timothy grass ve so far remained unknown, except that it flowers long days[4] and that spring sowings may lead to r formation in the same year[1]. In view of the ronomic importance of the plant, some clarification peared desirable.

Two similar experiments were conducted, one in 53, the other in 1954. In the first year, seed of *S*.48 nothy, after being vernalized according to the thod of Purvis and Gregory[5] for 8, 6, 4, 2 or weeks, was sown in soil on April 10. Immediately germination one-half of the seedlings in each atment was exposed to long-day conditions exnded to sixteen hours by artificial illumination, ile the other half passed through an initial phase four weeks in short days (eight hours). At the d of this period, both sets of plants were transnted into pots and placed in a latin square design t of doors under natural day-length conditions. In 54 the experiment was carried out in the same way, except that vernalization treatments of 16, 8, 4 or 0 weeks were given, after which the seed was sown on April 12.

Records of ear emergence on the main stem and the first three tillers were kept. The mean number of days to ear emergence on the main stem are given in Table 1.

In both years ears were produced under all treatments, including non-vernalization followed by long-day conditions from germination. Analyses of variance showed no significant differences with vernalization and day-length treatments in the time taken to ear emergence during 1953. In 1954, vernalization appeared to have had some influence, just significant at the 5 per cent level. The effect was, however, not consistent with increasing length of treatment and can scarcely be said to indicate a response to low temperature. No difference with day-length treatment was apparent. Similar relations held if leaf number was taken as a measure of time to ear emergence. Hanson and Sprague[6] have shown that the time taken to differentiation and ear emergence in timothy varies only slightly with temperature during an initial four weeks of short days, but depends mainly on temperature conditions during the long-day period.

During 1953 long-day treatment resulted in a significantly greater number of ears per plant being produced. This was an effect of increased tillering under these conditions, as shown by covariance of ears on number of tillers. Vernalization had no effect in 1953, but in the repeat experiment a significant difference ($p < 0{\cdot}05$) occurred, due apparently to an unusually high figure for one treatment. There was no indication that increasing exposure to low temperature or short-day conditions had led to greater ear production. Evidence that ear-bearing capacity of successive tillers is not entirely controlled by day-length will be presented elsewhere.

Since neither seed vernalization nor initial short-day treatments had any consistent effect, the conclusion seems warranted that timothy grass does not normally require low-temperature exposure or short-day induction for the production of inflorescences.

## Charge acquired by Powdered Salts on moving over Metal Surfaces

One of the common principles of contact electrification is that considerable electrification accompanies the relative motion of two surfaces only if one or both of them has a low electrical conductivity. Dealing with the electrification which occurs when a powder or sand flows down an inclined earthed metal surface, Hudson[1] has shown, by an indirect method, that a typical insulator (zircon sand) acquires a much larger charge than a semiconductor (rutile sand). Hudson's findings were confirmed by measuring directly the charge acquired by these sands from various lengths of an earthed aluminium chute. Fig. 1 shows the results for sands of 114μ average particle size.

The attainment of a limiting charge by the rutile is attributed to the establishment of a balance between the charging action (the nature of which is still obscure[2]) and a recombination of the separated charge caused by leakage due to the conductivity of the rutile[3]. The absence of such leakage with insulator particles allows the extended accumulation of charge, as found with zircon sand. Similar behaviour was found when the electrification was tested of glass microspheres in various states of preparation with respect to adsorbed moisture. Dry microspheres (114μ average diameter) gave a pattern like curve *A*, normal ones a curve of intermediate shape, while microspheres having abnormal adsorbed moisture yielded a curve of the same shape as *B* (cf. Peterson[4] working with atmospheres of different humidities).

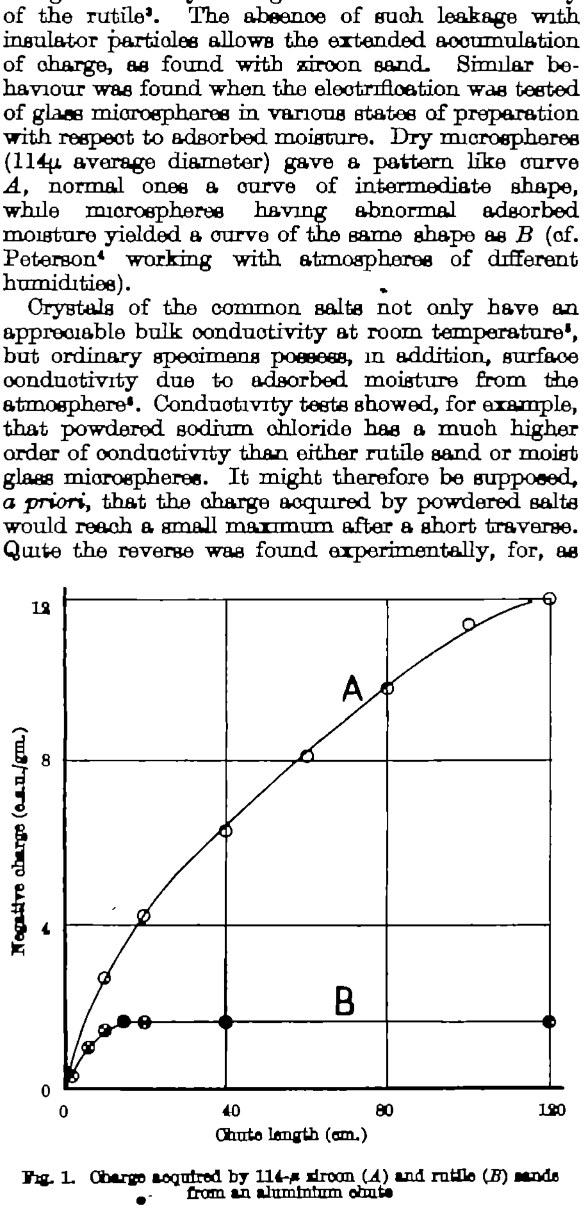

Fig. 1. Charge acquired by 114-μ zircon (*A*) and rutile (*B*) sands from an aluminium chute

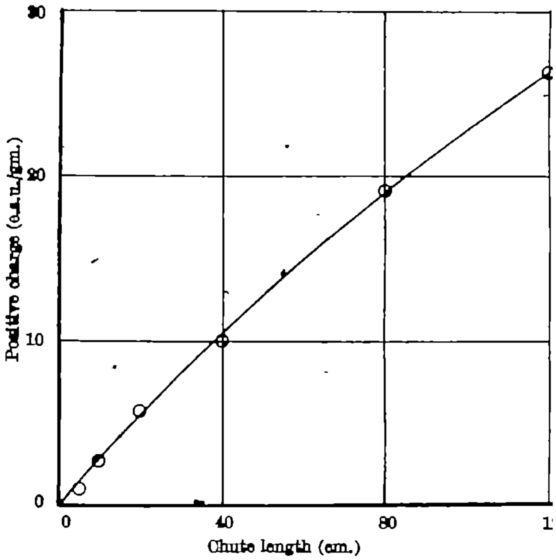

Fig. 2. Charge acquired by 211-μ sodium chloride particles from an aluminium chute

Crystals of the common salts not only have an appreciable bulk conductivity at room temperature[5], but ordinary specimens possess, in addition, surface conductivity due to adsorbed moisture from the atmosphere[6]. Conductivity tests showed, for example, that powdered sodium chloride has a much higher order of conductivity than either rutile sand or moist glass microspheres. It might therefore be supposed, *a priori*, that the charge acquired by powdered salts would reach a small maximum after a short traverse. Quite the reverse was found experimentally, for, as Fig. 2 shows, powdered sodium chloride (211μ ave age particle size) was electrified intensely by aluminium chute, and the accumulation of char with distance showed almost no sign of falling o despite the high conductivity of the salt. Other ion compounds gave similar results, both negative a positive electrification being found with differe compounds on various metal chutes. The effect removing the moisture film from powdered sodiu chloride (by evacuation for two hours) was to mal it acquire a much smaller charge from the aluminiu chute, namely, + 5·1 e.s.u. per gram from a 120-c traverse compared with + 26·4 acquired by the sa before evacuation.

The magnitude of the tribo-electric effect display by salts on metals shows it to be an importa electrokinetic phenomenon. The rule that hi conductivity leads to only slight electrification clearly disobeyed. Further experimental work, whi is being prepared for publication, suggests that th is due to ion transfer being the governing factor electrification, whereas the rule has been based o systems involving predominantly electron transfer.

I wish to thank Prof. M. B. Donald for his intere in, and encouragement of, this work, which w carried out at the Ramsay Laboratory, Universit College, London. The South African Council f Scientific and Industrial Research provided financi assistance, and Messrs. British Titan Products, Ltd gave the mineral sands used.

## Thermal Expansion of Coal

HE physical properties of coal have not yet been uately studied. Consequently, proposed models oal structure cannot be tested nor apparently flicting experimental observations reconciled. We ocate that accurate measurement of such pro- ies of coal as the thermal expansion, electrical ductivity, and response to mechanical stress ld be made concurrently with chemical and sical researches which seek to elucidate the cture of the material in increasingly specific ns.

ccordingly, we have made preliminary measure- nts of the coefficient of thermal expansion of a ted range of British bright coals in a direction llel to the bedding plane and normal to the main t over the temperature range 77°–293° K.

hanges in the length of small coal lumps have n measured by a capacitance method which has n chosen as sufficiently accurate and convenient he first instance. The condenser assembly consists a fused quartz plate upon which rests a short nder of the same material bearing the upper con- ser plate, a circular copper disk 30 mm. in neter with three lugs. Resting upon the quartz e and within the cylinder is a disk of copper upon ch stand three like coal specimens supporting lower condenser plate. The whole assembly is tained within a vessel which can be evacuated chilled. The coal specimens are cut from bright ain in the form of tetrahedra 10 mm. high the es of which are parallel to the main cleat. We e not yet measured the coefficient of thermal ansion parallel to the main cleat or normal to bedding plane. The capacity change resulting n a change in the temperature of the coal specimens in these experiments been measured by a com- cial instrument in which the incremental capacity be caused to occupy the whole of the measuring le.

he measurements relate to dry coal, the specimens ing been exposed over magnesium perchlorate thirty-six hours before use and the vessel con- ing the complete electrode assembly maintained $0^{-1}$ mm. mercury for the twelve hours before the oduction of nitrogen (15 mm. mercury) in readi- s for initial measurement and chilling. The ervations made have included the change in linear ension on chilling from room temperature to K. and, using a series of refrigerants, during ming from that temperature to room tempera- .

ur results for four British bright coals, including mple of anthracite (sample *D*), are in Table 1. se supplement the few published values of which are aware, namely, $20{\cdot}78 \times 10^{-6}$ for anthracite[1] $42 \times 10^{-6}$ for a low-rank bituminous coal[2] bon content 82·6 per cent dry mineral-free s).

e 1. COEFFICIENT OF EXPANSION IN THE BEDDING PLANE OF BRIGHT COAL ($\times 10^{-6}$)

| Coal | *A* | *B* | *C* | *D* | |
|---|---|---|---|---|---|
| cbon, per cent dry, uneral-free basis | 82 | 87 | 90·5 | 94·5 | |
| mperature range (° K.): | | | | | |
| 293– 77 | 40 | 61 | 36 | 51 | 22 |
| 77– 90 | 35 | 53 | 42 | 54 | 12 |
| 90–217 | 43 | 40 | 47 | 23 | 8 |
| 217–273 | 42 | — | 31 | 49 | 36 |
| 273–293 | 35 | 49 | 59 | 31 | — |

The mean values for the full temperature range are probably accurate to $\pm 2 \times 10^{-6}$. The error in the values ascribed to intermediate temperature ranges may be somewhat larger. We are aware of imperfections in both the method and the apparatus. These we hope to reduce. Nevertheless, the values stated are sufficiently accurate to be useful.

The similarity between the observed values for the three bituminous coals (*A*, *B* and *C*) suggests that the differences in the arrangement of solid and space which are consequent upon the change in rank from low-rank non-caking to coking coal have been almost offset by changes in the properties of the solid. The wide range in the values obtained with two sets of anthracite specimens (*D*) reflects the anisotropy of the material.

We do not doubt that if such data had been available a few years ago the inappropriate over-simplification of such a model for coal as that of Bangham[3] would quickly have been apparent.

We hope to continue our measurements with increasing accuracy and completeness.

## *F*-Centres in Metaphosphate Glass

A NUMBER of investigators[1] have shown that glass on exposure to radioactive and X-radiation becomes coloured. Sheline, Sharp and Arner[2] suggested that this may be due to *F*-centres similar to those produced in alkali halides when bombarded by X-rays and cathode rays. Yokota[3] found that *F*-centres could be created in fused silica and α-quartz by X-irradiation. He further showed that alkali silicate and borate glasses become coloured on X-irradiation due to formation of *F*-centres[4]. Przibram[5] showed that *F*-centres could also be created in borate glass by β- and γ-irradiation from radium.

I have found that *F*-centres can be produced very easily in metaphosphate glass by X-irradiation from a copper target (30 kV., 15 m.amp.). These metaphosphate glasses were prepared by heating sodium dihydrogen phosphate in a platinum tray at 900° C. for 1 hr. Variation in the composition of the glass could be introduced by heating mixtures of sodium dihydrogen phosphate and disodium hydrogen phosphate, and mixtures of sodium dihydrogen phosphate and ammonium dihydrogen phosphate. In the first case, sodium was in excess of the stoichiometric composition, while in the second case phosphate radical was in excess, ammonia disappearing during heating. Composition, however, could not be varied over a wide range, for metaphosphate glass with higher sodium content tended to crystallize out rather quickly.

Absorption spectra measurements were carried out with glass plates (0·8 mm. thick) in a Beckman spectrophotometer model *DU*. The irradiated glass system showed two peaks in the visible region at 510 mμ and 490 mμ respectively, and one in the ultra-violet region at 340 mμ. With increase in sodium concentration in the glass, the intensity of absorption in the visible region increased, with slight shift towards longer wave-length, but that in the ultra-violet region was more or less unchanged.

These facts indicate that the visible band is due to electrons trapped at negative ion vacancies, and the ultra-violet band is probably due to trapped holes at positive ion sites. Comparing the absorption spectrum of metaphosphate with those of borate and silicate glasses, it is noted that the positions of ultra-violet and visible region bands in all three glass systems are the same, suggesting some similarity in the trapping mechanism in all these cases.

Schulman[6] has shown that metaphosphate glasses in which aluminium, barium, silver, etc., have been dissolved can be used as dosimeters for γ-rays by their radio photoluminescence. This phenomenon can be explained as the production of *F*-centres, and Schulman attributed this to the activating influence of the added metal present in the glass. The present communication shows that *F*-centres can be produced very easily without these activators.

Thanks are due to Mr. S. Bhattacharyya for his help.

## Effect of Chelating Agents on Heterogeneous Catalysis

Chalk and Smith[1] have recently reported that the autoxidation of *cyclo*hexene, catalysed by dissolved heavy metal soaps, is accelerated by chelating agents. It has been discovered in this laboratory that chelating agents may also increase the rate of autoxidation which is heterogeneously catalysed by metallic copper.

The rate of oxygen absorption by transformer oil was compared with that by transformer oil containing 0·25 weight per cent of chelating agent, both in the presence and absence of solid copper. The chelating agents used were α,α′-dipyridyl, disalicylal ethylenediamine, and 'Versenes' 123, 123*a* and 123*b* (the 'Versenes' are commercial, oil-soluble chelating agents and are reported to be amino-acetic acids substituted with long alkyl chains).

Oxidation tests were carried out by placing 10-ml. samples of the oil in Sligh flasks, filling the flasks with oxygen to a pressure of about 800 mm. mercury, and connecting each flask to a manometer. The course of the autoxidation was followed by measuring the decrease of pressure while the flask was kept at 120° C. The copper catalyst used consisted of 35 turns of No. 18 electrolytic copper wire wound on a 0·21-in. diameter mandrel. The transformer oil used was not entirely free from traces of heavy metals, since analysis revealed that it contained 0·1–0·2 p.p.m. of dissolved copper.

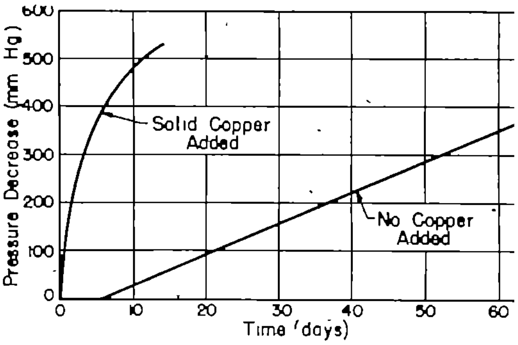

Fig. 1. Oxygen absorption of transformer oil

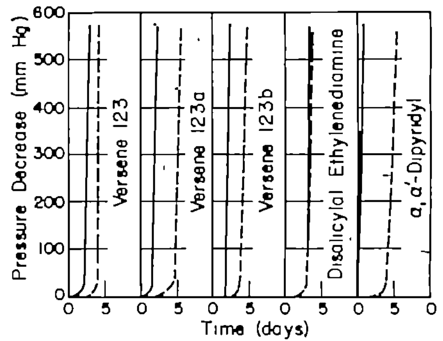

Fig. 2. Oxygen absorption of transformer oil with 0·25 per c chelating agent: ———, solid copper added; – – – –, no copp added

The results shown in Figs. 1 and 2 confirm the that chelating agents will accelerate homogene autoxidation and also show clearly, particularly the case of α,α′-dipyridyl, that they may accelerate the heterogeneously catalysed reactio

It will be noted that, for several chelating age the addition of the chelating agent to oil in con with solid copper results in an induction perio several days before rapid oxidation commen Thus, although these materials are powerful oxidants for heterogeneous catalysis, if observat are confined to the initial stages of the reaction, will appear to be antioxidants.

I am indebted to the Alrose Chemical Comp for a sample of disalicylal ethylenediamine an the Bersworth Chemical Company for sample their 'Versenes'.

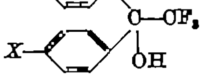
## A New Group of DDT Synergists

In a study of the influence of structural variat on the insecticidal activity of DDT, the di (trifluoromethyl)-carbinols



(*X*=H, F, Cl, Br, $OCH_3$, $OC_2H_5$, $CH_3$, ‘e been prepared by reaction between ethyl ıuoroacetate and the appropriate arylmagnesium mides ; the dinitro-derivative has been synthesized nitration of the diphenyl compound[1]. The in- icidal potency of the new compounds was practic- nil, only the *p*-dichloro-compound exhibiting a ht activity.

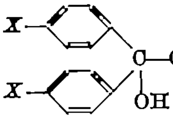
arvicidal tests were somewhat more satisfactory. these tests the contact toxicity for third-stage ræ of *Musca vicina* Marq.[2] was compared with t of γ-benzene hexachloride and di-(*p*-chloro- nyl)-methylcarbinol ; the percentage of normal æ and adults emerging from the larvæ was ermined (Table 1).

Table 1

| | Concentration (gm./sq. m.) | Normal pupæ (per cent) | Normal adults (per cent) |
|---|---|---|---|
| t-(*p*-chlorophenyl)-(tri- tuoromethyl)-carbinol | 1 0 | 56 | 6 |
| | 0·5 | 85 | 66 |
| t-(*p*-chlorophenyl)- nethylcarbinol | 1 0 | 90 | 52 |
| | 0 5 | 92 | 81 |
| Benzene hexachloride | 1 0 | 2 | 1 |
| | 0·5 | 3 | 2 |
| ntrol | — | 96 | 85 |

Table 2.

ERGISTIC ACTIVITY OF THE CARBINOLS



| Carbinol, *X* = | $\frac{\text{DDT}}{\text{Carbinol}} = 10:1$ | $\frac{\text{DDT}}{\text{Carbinol}} = 1:1$ |
|---|---|---|
| Cl | 15 | 25 |
| F | 10 | 16 |
| Br | 12 | 16 |
| $OCH_3$ | 5 | 12 |
| $NO_2$ | 4 | 10 |
| $OC_2H_5$ | 0 | 4 |
| $CH_3$ | 0 | 4 |

The above carbinols have, however, proved to be cellent synergists for DDT. Benzene solutions of T and the synergist were topically applied (micro- p method) to groups of twenty-five represent- ves of a laboratory strain of *Musca vicina* y slightly resistant to DDT (strain *A*) and of a ected strain (*B*), fourteen times more resistant than ain *A*. Mortalities were determined after 24 hr. e synergistic activities (a synergistic activity of *n* ans that it is possible to reduce the dosage of T to 1/*n* without decreasing the effect) observed strain *A* are shown in Table 2.

For strain *B* all these figures were approximately times higher. Comparison with some of the most ive synergists known[3] show that di-(*p*-chloro- enyl)-(trifluoromethyl)-carbinol is 2·5 times more ive than di-(*p*-chlorophenyl)-methylcarbinol, 2·0 es more than di-(*p*-chlorophenyl)-methyl chloride d 1·5 times more than 1,1-di-(*p*-chlorophenyl)- ane.

The close structural analogy between DDT and most potent synergists is noteworthy. Adopting theory of the mode of action of the insecticide ich has recently been proposed by Gunther *et al.*[4], e may assume that the synergists occupy pre- entially the site at which DDT is metabolized and reby inactivated. The synergists would thus event the inactivation reaction and appear to bear same relation to the insecticide as an anti- tabolite to the normal metabolite. Similar theories of ‘competition by displacement’ have been suggested for the phenomenon of synergism by Perry *et al.*[5], and by Speroni and co-workers[6].

## Ester Groups in Lignin

THE main high-molecular phenolic constituent of woody plant tissues, lignin, is partly soluble in neutral organic solvents. The methanol-soluble fraction known as ‘native’ lignin generally shows an ultra-violet absorption spectrum with strong end-absorption and weakly resolved bands at 280 and 350 mμ[1].

The native lignin from sugar cane differs from other lignin in this respect, having a distinctive ultra-violet absorption spectrum (Fig. 1). This has been attributed to the presence of substituted *p*-hydroxyphenylketone groups[2]; but it has now been shown that these distinctive absorption bands are due to the presence of *p*-hydroxycinnamic ester groups. This is only the second time that ester groups have been reported in a lignin (cf. ref. 3).

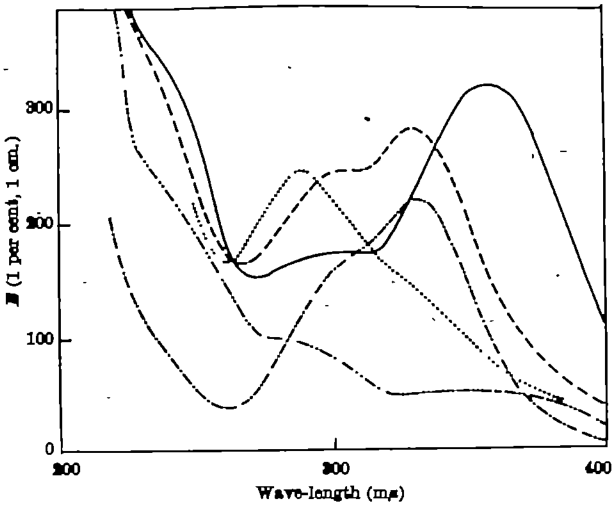

Fig. 1. Ultra-violet absorption spectra of fractions from sugar cane native lignin in aqueous sodium hydroxide

———, Lignin in 0·01 *N* sodium hydroxide ; - - - -, lignin in *N* sodium hydroxide after standing 4 hr. at room temperature (*A*) ; . . . . ., lignin in *N* sodium hydroxide after standing two days at room temperature ; –·–·–·–, material extracted from (*A*) at *p*H 4 by ether ; spectrum measured in *N* sodium hydroxide ; –··–··–··–, material not extracted from (*A*) at *p*H 4 by ether ; spectrum measured in *N* sodium hydroxide

Whereas in aqueous 0·01 *N* sodium hydroxide the absorption spectrum of sugar cane native lignin is unchanged for many hours, in *N* sodium hydroxide the absorption maximum at 355 mμ moves to 330 mμ over a period of about four hours, and a subsequent slower process results in replacement of the two maxima at 300 and 330 mμ by a single maximum at 290 mμ (Fig. 1). *p*-Hydroxycinnamic acid (33 mgm.) was isolated from a solution of lignin (300 mgm.) at the end of the first process of transformation in alkali, by acidification, extraction with ether and recrystallization from water. The acid was further purified by vacuum sublimation (melting point 211–212° decomp., undepressed on admixture with an authentic sample. Found: C, 66·3; H, 5·2; calc. for $C_9H_8O_3$: C, 65·9; H, 4·9 per cent).

The initial transformation of sugar cane native lignin in alkali is paralleled closely by the hydrolysis of methyl *p*-hydroxycinnamate (absorption maximum at 353 mμ in dilute alkali), suggesting that a similar ester linkage is present in the lignin. The later stage of transformation in alkali receives a partial explanation in that *p*-hydroxycinnamic acid decomposes in *N* sodium hydroxide to give a single absorption band at 290 mμ. Paper chromatography of the ether extract at the end of the initial stage of transformation showed the presence not only of *p*-hydroxycinnamic acid, but also of small amounts of *p*-hydroxybenzoic acid, vanillic acid, syringic acid and ferulic acid.

Native lignins from wheat straw, Douglas fir wood and horse chestnut wood were examined for comparison. Only with wheat lignin does the absorption spectrum show appreciable hydrolytic transformation in *N* sodium hydroxide, and paper chromatography of the ether extract showed the presence of *p*-hydroxycinnamic acid and ferulic acid, accompanied by traces of vanillic acid and syringic acid. Douglas fir lignin yielded traces of *p*-hydroxybenzoic acid and vanillic acid; horse chestnut lignin yielded traces of vanillic acid, *p*-hydroxycinnamic acid and ferulic acid.

The infra-red spectra of these lignins in the region 5·5–6·5μ provide additional evidence for the presence of ester groups in two of them. The absorption bands in this region are given in Table 1.

Table 1. Position of Infra-red Absorption Bands (cm.$^{-1}$)

| | | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| *Lignins* | | | | | | | | |
| Sugar cane | 1,695 | 1,662 | | 1,621 | | 1,597 | 1,585 | |
| Wheat straw | 1,697 | | 1,645 | | 1,612 | 1,599 | 1,587 | |
| Douglas fir | | 1,657 | | 1,624 | | | 1,589 | |
| Horse chestnut | | 1,660 | | | | 1,590 | 1,584 | |
| *Model substances* | | | | | | | | |
| Methyl *p*-hydroxycinnamate | 1,694 | | | 1,621 | | 1,598 | 1,581 | |
| Ferulic aldehyde | | 1,660 | | | 1,611 | 1,598 | 1,581 | |
| 3 : 4-Dimethoxycinnamaldehyde | | 1,661 | | | 1,611 | | 1,583 | 1,575 |
| Vanillin | | 1,670 | | | | | 1,586 | |
| Veratric aldehyde | | 1,667 | | | | | 1,588 | |
| Acetovanillone | | 1,657 | | | | 1,591 | 1,582 | |

The bands at 1,695 and 1,697 cm.$^{-1}$ in sugar cane lignin and wheat straw lignin can be allocated, by comparison with methyl *p*-hydroxycinnamate, to ester-carbonyl stretching vibrations. Likewise the bands at 1,657–1,662 cm.$^{-1}$ in the lignins are probably due to aldehyde or ketone stretching vibrations. These spectra were obtained with a single-beam spectrometer using 10 per cent and 7 per cent solutions of lignins and model substances respectively, in dioxan. A thickness of 0·01 mm. of solution used and the band of dioxan at 5·8μ was elimin by subtraction.

It appears from the nature and distribution ester residues in these cases that ester residues attached to pre-formed lignins, and so do not th light on the basic structure of these substances.

This work forms part of the programme of Food Investigation Organization of the Departm of Scientific and Industrial Research.

## Colorimetric Determination of Micro Quantities of Calcium

The reaction of murexide (ammonium purpura with calcium ions to give the colour-change pur to red has long been known. It was recently stud spectrophotometrically in detail by Schwarzenb and Gysling[1]. As a result of this work, Oster and Rinck[2] proposed a method for the colorime determination of calcium. They chose to work pH 6·2, where the colour is very stable. We ha found, however, that if the determinations carried out at pH 11·0 (using potassium or sodi hydroxide), the colours are sufficiently stable ( appreciable change in 15 min.) to be readily termined, while the sensitivity of the method can increased at least fifty times. Thus, quantities calcium in the range (0–8) μgm./10 ml. can be read estimated. At pH 6·2 the method is quite insensit over this range.

The murexide solution was prepared fresh da and contained 20 mgm./l.

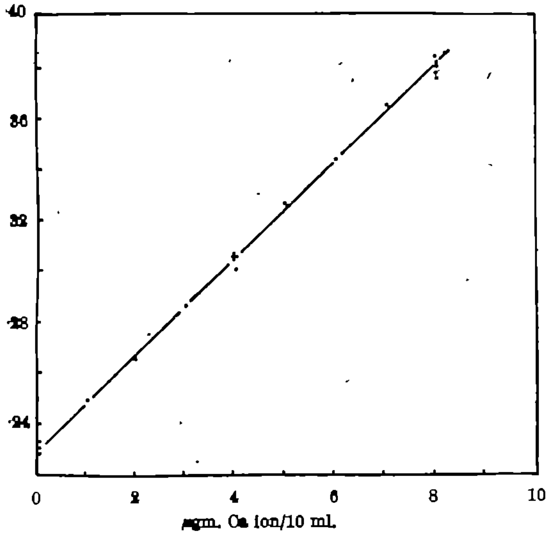
The red colour due to the calcium was determin against distilled water on a Hilger Spekker absorpt meter using the Ilford spectrum blue-green filter N 603 and 1-cm. cells. (At higher calcium concent tions, the loss in the blue colour of the murexide m be determined using the spectrum yellow filter N 606.)

A known volume of calcium solution was added 1 c.c. of 0·03 *N* potassium hydroxide and the soluti made up to 5 c.c. with distilled water. 5 c.c. murexide was added immediately before determini the colour.

Fig. 1 shows the linear relationship between t colour and concentration of calcium. This curve reproducible, and the colour-change over the ran (0–8) μgm. $Ca^{2+}$/10 ml. is quite considerable.

Ammonium, sodium, potassium, aluminium a manganese ions, when present in twenty-fold exc (on a molecular basis) over the calcium, do not sh any interference with the colour due to the calciu A similar result is obtained with barium ions in te fold excess.

There is considerable interference from copp zinc, cadmium, mercuric, silver and cobalt ions ev when present in comparable amounts to the calciu Under the latter conditions of concentratio



ig. 1. 1 ml. potassium hydroxide solution; *x* ml. solution of lcium; distilled water to 5 ml. plus 5 ml. murexide solution (20 mgm./l.). Final pH, 11·2

ontium and magnesium ions give a result which 10 per cent too high, while ferrous and ferric ions e a result 4–5 per cent too low.

The use of potassium cyanide (~ 1 gm./l.) in the assium hydroxide completely eliminated interence from copper, mercuric, silver, cobalt and lmium ions. The effects due to zinc, ferrous, ric, strontium and magnesium ions are largely affected.

We wish to thank the Directors of the County boratories, Ltd., for permission to publish this nmunication.

## Cellular Electrolytes and Adrenal Steroids

r has long been established that deficiency in enal cortical hormones can give rise to loss of racellular sodium, and that excess of these hornes leads to a retention of sodium and water by ue cells, with a loss of intracellular potassium.

The distribution of electrolytes between red cells l plasma in Addison's disease and Cushing's idrome has been investigated in this laboratory. three cases of Addison's disease the plasma sodium s lowered and the potassium raised; but in the cell these electrolytes remained unchanged. The ults of the red-cell analyses were not unexpected, ce the cellular electrolytes of adrenalectomized mals remain normal unless the animals are mainned on water only. In two cases of Cushing's idrome the plasma sodium was found to be normal l the potassium-level depressed; again, the red- content of both sodium and potassium was mal. It is highly probable that the rates of movent of sodium and potassium across the red-cell nbrane are significantly influenced by adrenal roids, and Streeten and Solomon[1] have demonstrated that corticotrophin (ACTH) or cortisone administered to patients caused a slowing of the rate of influx and efflux of potassium across the red-cell membrane, without leading to the anticipated net loss of cellular potassium. Furthermore, hydrocortisone *in vitro* produced a similar response.

To test whether the human erythrocyte was suitable for the investigation of hormone effects on electrolytes, the following *in vitro* experiment was carried out. Human blood was heparinized and cold-stored at 4°–6° C. for six days. During this period the red-cell sodium concentration doubled, the potassium fell and water increased. The cold-stored cells were next incubated for 3–5 hr. at 38° C. in a Krebs–Ringer bicarbonate buffer. Glucose was added to all samples, and deoxycorticosterone was used to test the influence of adrenal steroids on the active transport of sodium. In samples incubated with glucose alone, there was a considerable extrusion of sodium and water by the red cells. The effect of added deoxycorticosterone was significantly to inhibit this active transport. During the incubation period the red cells gained potassium, a gain which was not found in the presence of deoxycorticosterone. The results of a typical experiment are given in Table 1.

Table 1. EFFECTS OF DEOXYCORTICOSTERONE ON ACTIVE SODIUM TRANSPORT IN HUMAN RED CELLS

Incubation carried out at 38° C. in Krebs–Ringer bicarbonate, pH 7·4; gas phase 5 per cent carbon dioxide in oxygen. Glucose concentration 0·01 *M*. Time 3·0 hr.

| | Sodium (m.equiv./l. cells) | Net sodium change | Potassium (m.equiv./l. cells) | Water (gm./l. cells) |
|---|---|---|---|---|
| Cold-stored red cells | 46·0 | | 70·0 | 740 |
| Red cells incubated with glucose | 34·0 | 12·0 | 76·0 | 728 |
| Red cells with glucose and deoxycorticosterone | 41·0 | 5·0 | 70·0 | 734 |

The effect of deoxycorticosterone on cellular electrolytes was therefore to inhibit the active transport of sodium from the cells; it might, therefore, be expected to give rise *in vivo* to pathological retention of sodium and water. It has previously been found to have a similar action on yeasts[2] and on rat tissues by Schatzmann[3]. Cortisone has been found to be without influence on the sodium transport of human red cells (Maizels, personal communication).

It is generally believed that the active transport of ions in tissue is dependent on the energy metabolism of the cell, and there is some evidence to show that adrenal steroids influence the electrolyte distribution by means of their effect on energy metabolism. The observations reported above may facilitate the study of hormone activity, electrolyte distribution and energy metabolism in human cells.

The investigations recorded above are part of a research programme suggested by Sir Henry Cohen. The use of deoxycorticosterone was suggested by Dr. I. Chester Jones (Liverpool) and the drug kindly given by Ciba Laboratories. I wish to acknowledge discussions with Prof. H. A. Krebs and his colleagues, Prof. M. Maizels and Prof. C. H. Gray. Skilled technical assistance was given by Mrs. Anne Chambers.

# FORTHCOMING EVENT

## Wednesday, August 10—Friday, August 12

Faraday Society (in the University Laboratory of Physiology, Parks Road, Oxford)—General Discussion on "The Physical Chemistry of Enzymes".

---

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Physicists (with a university degree or equivalent qualification in physics) at the Research Laboratories, Central Electricity Authority, Leatherhead, for duties which include research on problems associated with the generation and transmission of electricity—Director of Establishments, Central Electricity Authority, Winsley Street, London, W.1, quoting AH/643 (August 10).

Lecturer (preferably with special qualifications in micro- and semi-micro- analytical techniques) in Chemistry—The Secretary, The University, Aberdeen (August 20).

Divisional Chief Scientist (fully qualified in one of the pure or applied sciences (chemistry, physics, chemical engineering or fuel technology), and good industrial or research experience)—National Coal Board, Secretariat (H), Cambrian Buildings, Mount Stuart Square, Cardiff (August 24).

Head of the Physics Department—The Principal, Derby Technical College, Normanton Road, Derby (August 29).

Assistant in Natural History—The Secretary, The University, Aberdeen (August 31).

Assistant Lecturer or Lecturer (with a degree or diploma in horticulture and experienced in ornamental horticulture and landscape gardening) in Horticulture, at Canterbury Agricultural College (University of New Zealand)—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, August 31).

Demonstrator in the Department of Inorganic Chemistry—The Registrar, King's College, Newcastle-upon-Tyne (August 31).

Senior Lecturer in Anatomy—The Dean of the Medical College, St. Bartholomew's Hospital, West Smithfield, London, E.C.1 (August 31).

Research Assistant (with a physics degree) in the Geophysics Section of the Geology Department—The Professor of Geophysics, Imperial College of Science and Technology, London, S.W.7 (September 1).

Lecturer (preferably with an interest in algae, especially marine algae) in the Department of Botany at the University of Cape Town—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Cape Town, September 2).

Lecturer in Sociology—The Registrar, The University, Hull (September 3).

Assistant Lecturer in Metallurgy—The Registrar, The University, Manchester 13 (September 7).

Edward A. Deeds Senior Fellow for research in engineering, metallurgy, chemistry, physics, mathematical physics or any cognate subject—The Secretary, Deeds Fellowship Committee, Queen's College, Dundee (September 7).

Lecturer in Engineering—Joint Clerk to the University Court, Queen's College, Dundee (September 15).

Lecturer (with a good honours degree in metallurgy) in Metallurgy—The Registrar, College of Technology, Manchester 1 (September 15).

Lecturer (graduate in science or technology, and a good knowledge of the theory of structures) in Structural Engineering—The Registrar, College of Technology, Manchester 1 (September 19).

Reader in Soil Science—The Registrar, University Registry, Oxford (September 29).

Director of Adult Education at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, September 30).

Professor of Metallurgy at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, September 30).

Chair of Botany at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong, October 15).

Assistant Lecturer (Grade A) in the Department of Applied Physics—The Secretary, Northampton Polytechnic, St. John Street, London, E.C.1.

Demonstrator in Physics—The Registrar, The University, Nottingham.

Field Studies Instructor (with a degree in geography or a general science degree, and preferably some teaching experience) at Glenmore Lodge, Scottish Centre of Outdoor Training, Aviemore, Inverness-shire—The Secretary, Scottish Council of Physical Recreation, 4 Queensferry Street, Edinburgh 2.

Plant Breeder, Scientific Officer, Senior Scientific Officer or Principal Scientific Officer grade (with at least a second-class honours degree and experience in plant breeding), in the West African Maize Rust Research Unit, Nigeria, to carry out research into maize rust—Director of Recruitment, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting BCD.197/376/01.

Scientific Officers (with a first- or second-class honours degree, or equivalent, in mathematics, physics or economics) with the Air Ministry, for operational research in or near London—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.384/54A.

# NUCLEAR POWER AND ITS UTILIZATION

CE President Eisenhower first made his proosals, less than two years ago, for an internal pool of atomic materials for peaceful ses, optimism as to the immediate future of r energy has steadily grown. Before the national Conference on the Peaceful Uses of ic Energy had opened at Geneva, Great Britain he United States had given practical effect to proposals for promoting internationally the uctive use of nuclear energy by making fissionmaterial available for use in nuclear research rs overseas and by offering to train foreign ists. On June 11 President Eisenhower, ing at Pennsylvania State University, indicated he proposed to extend this programme by asking ess to agree to meet half the costs of building ch reactors for free nations, including a supply e necessary nuclear fuel, and to provide, within ity considerations, information and experts to friendly nations in the construction of full-scale r stations.

ese proposals are of special interest to the underoped countries, for President Eisenhower exly contemplated support of the voluntary groupf the resources of several nations within a single n, in order to acquire and operate together a rch reactor which individually they lacked the ical or material resources to use effectively. have also undoubtedly contributed to the more ful climate of opinion in which the Geneva rence has met. Concerned essentially with the nge of technical information and opinion on a range of subjects from piles and power plants, e biological hazards of radioactive materials, the sal of wastes and the uses of radioactive rials in industry, in medicine and in agriculture, ccess or failure largely turns on the extent to n free discussion and exchange of views and mation are unhindered by questions of secrecy. dent Eisenhower's proposals in June gave raging evidence that this danger was remote the potential spread of knowledge was unlikely ll into operation the restrictive clauses of the ahon Act.

t until the Conference concludes can it well be how far a more realistic and reasonable view of cy in nuclear science and technology has come revail. The Anglo-American agreements on ar energy, published shortly after President hower's statement in June, were disappointing indicated that even between the United States Great Britain we had still a long way to go before ll exchange and cross-fertilization of ideas in ar research was possible, and the overlapping fort, particularly by scarce scientific man-power, ced to an inescapable and justifiable minimum. e will indeed be a greater exchange of information he effect of weapons on civil defence, on the ration of electric power, and on fissile materials; while it is still so difficult to separate the effort nded on nuclear research and development for peaceful purposes from that expended for military purposes, an agreement which provides for no co-ordination of fundamental research programmes and no exchange of information on the design and manufacture of nuclear weapons scarcely amounts to partnership.

Whether, in view of what the National Science Foundation has already reported as to the man-power situation, the United States can continue to afford the waste of man-power and technical resources thereby involved is their affair; but Great Britain at least can scarcely regard with indifference the loss of any opportunity of conserving her limited resources at a time when the demand upon them is still increasing. Since the publication in February of the White Paper outlining the Government's programme for the development of nuclear power in Great Britain, the Minister of Fuel and Power, Mr. Geoffrey Lloyd, has announced that six more nuclear reactors are to be built in Cumberland. These reactors, Mr. Geoffrey Lloyd said in the debate on the Queen's Speech on June 13, are additional to those proposed in the £300 million programme announced in February. They will be designed to produce both electric power and fissile material for military purposes, and will be of the same kind as those now being constructed at Calder Hall. The Minister also said that four main industrial groups have now been formed to develop this industry. They include Associated Electrical Industries – John Thompson; the English Electric – Babcock and Wilcox; the General Electric Company – Simon Carves; and C. A. Parsons – Head Wrightson – A. E. Reyrolle, registered recently as the Nuclear Power Plant Co.; and Foster Wheeler, Ltd., is engaged in research on the cooling of nuclear power reactors and has facilities for the design, manufacture and erection of equipment for reactor cooling. It should also be noted that the Institutions of Civil, Mechanical, Electrical and Chemical Engineers, together with the Institute of Physics, early in June constituted the British Nuclear Energy Conference as a permanent body, under the chairmanship of Sir Charles Hinton, for organizing meetings, symposia, the publication of papers, etc. This development was welcomed by the Minister, who also referred to the success of the training courses for engineers arranged by the Atomic Energy Authority. The new design organizations staffed by engineers so trained, he said, are already at work, producing ideas of their own and still in close touch with engineers of the Atomic Energy Authority.

This stepping up of the Government's plans, Mr. Geoffrey Lloyd told the House of Commons in the debate on the National Coal Board on July 20, will enable nuclear energy to contribute substantially to power production as from 1960. In that debate the Minister indeed proposed to meet the coal shortage by substituting oil for coal on a large scale during the next five years; but he gave no sound basis for the assumption that even the present output of coal can be maintained. It might well be sounder to expand still further the programme for building nuclear stations. An expenditure of some £60 million on such stations would allow us to save about a quarter of the £80 million we are at present spending on the import of coal, apart from economies concerned with the production of plutonium and the possible reduction in capital investment in the railways, which carry most of the country's coal.

It is true that electrical engineers expressed the opinion at the British Electrical Power Convention that nuclear power is being developed faster than is technically desirable, and stressed the importance of examining means of getting adequate supplies of concentrated fissile materials for the advanced types of generating stations to be built in the later stages of the new nuclear programme. Despite the generous tributes paid to the work of the Atomic Energy Authority and the contracting firms associated with the developments, it was emphasized that the United States, in view of the different lines upon which production for military purposes is proceeding there, has a considerable potential advantage in the design and operation of the advanced types of nuclear generating plant contemplated in the British programme. Sir Claude Gibb in particular stressed this potential advantage possessed by electrical engineers in the United States, and it is clear that the Anglo-American agreements as well as the present international conference offer considerable advantages to Britain.

None the less, Britain's own contributions are important, though it is well to remember that, as Prof. W. R. Hawthorne remarked in an article in the *Westminster Bank Review* last May, we are not in such a stagnant period of scientific invention in respect of the older sources of power that we need inevitably depend on nuclear energy alone. In fact, nuclear energy is unlikely to ease the fuel position much in Britain in the next fifteen years, although the nuclear power programme offers savings of about five or six million tons of coal per annum by 1965. Sir Francis Simon, in an article in *Lloyds Bank Review* of April, regards the White Paper as a little too optimistic; he assumes that after a development period of fifteen to twenty years nuclear electricity will cost about the same as electricity from coal. To build up a nuclear power system equal to our present generating capacity will involve expenditure of about £3,000 million, and in view of other capital commitments such a system is unlikely to be complete in less than twenty to twenty-five years.

Sir Francis Simon thus thinks it will be about the middle of the next century before we can count on nuclear fission meeting most of the power requirements of Britain. Although he regards the use of nuclear power to drive large power stations of the same magnitude as those burning the conventional fuels as the first main application of nuclear energy—and stresses throughout this development the importance of saving coal by using it more efficiently—he points out that nuclear energy makes possible the provision of large or medium-sized power stations in out-of-the-way places, to which the transport of conventional fuels is either impossible or prohibitively expensive. This was also stressed by Dr. J. Bronowski in an article in the special ninetieth anniver issue, entitled "Atoms for Peace", of the York periodical, *The Nation*, dated June 18. Bronowski, in fact, regards the ability of the nu pile to offer concentrated power precisely w it is wanted in regions remote from either or water-power as the most important applica of nuclear energy in large and thinly popul regions, like South Africa, which are rich in mine In the same journal, Prof. M. L. Oliphant makes n the same point in respect of the tropical and zones of Australia; but Sir Francis Simon goe to show how important this possibility is to Bri Under-developed centres are often under-devel because they have no power available, and he ar that the export of nuclear power stations is an i example of the kind of export on which Britain have to depend increasingly. We are only at very beginning of such developments. No nu power station has yet run under realistic conditi Commercial generating stations based on the C Hall experiment may be begun by about 1957 commence to operate in 1961; but although Dounray power station is to be of the fast-bre type, it is not anticipated that a commercial sta of this design can be tested in operation before 1 Many stations working on different principles have to be built and tested before we know whi the most reliable and economic, and while i national co-operation can facilitate the intercha of ideas between the best scientists and technolo in different countries, few countries can muster necessary scientific and industrial resources to at successfully such problems of development.

Sir Francis Simon considers that, for the time be only the United States, Great Britain and the So Union can be considered as serious competi for the nuclear export market to under-devel countries, where the negligible weight of nuclear offers possibilities in remote areas to which trans of coal or oil would be prohibitively expensive. urges that there are strong incentives, politica well as economic, for getting a hold on this ex market, but he stresses particularly the econ factor. The export of nuclear power station particularly suited to Great Britain. Apart from British genius for science and technology which already contributed to the present developme Britain's economy is large enough to permit deve ments on the necessary scale. Even an increas the power consumption of the non-industrial countries to one-third of that of the present Br consumption per head of population would re power stations worth twenty to thirty thou million pounds, while in the long run the fiel practically without limits.

Nor is this ideal and almost unlimited field British enterprise the only possibility to be sidered. Sir Francis does not answer the ques whether the coming of nuclear power heralds a industrial revolution, other than to suggest tha the middle of next century the world will prob derive most of its energy from nuclear sources, that for the under-developed countries nuclear p will usher in a new era by enabling industry t blished in places deprived of the conventional s. None the less, a resolution adopted by the eign Ministers of the Federal German Republic, gium, France, Italy, Luxembourg and The Netherls at their meeting at Messina on June 1 and 2 mes that the development of nuclear energy for eful purposes holds a prospect in the near future new industrial revolution out of all proportion that which has taken place during the past dred years. The six signatory States consider rdingly that it is necessary to study the creation common organization to be entrusted with the onsibility and the means for ensuring the peaceful elopment of nuclear energy, while taking into unt the special arrangements made by certain ernments with third countries.

he means contemplated comprise the establisht of a common fund to provide for research and elopment; free access to raw materials and free hange of techniques and technicians, by-products specialized equipment; the pooling of results; financial assistance in exploitation and coration with other countries. It seems clear from Prime Minister's remarks, quoted by Sir Francis on, that the British Government is fully alive to scope and potentialities of this entirely new ort trade throughout the Commonwealth and pire, and the possibilities of raising living dards in wide areas through nuclear power. ertheless, although he claimed that within two s the first power stations producing electricity ld be working in this field, and that already y British firms are exploring markets overseas their new products in this field, the reception n to the Messina resolution suggests that the ortunities in Europe are being overlooked.

he Messina resolution may, of course, prove to be of good intention rather than firm resolve; but ffers something more than the European Organion for Nuclear Research which Britain is already porting, and there are several reasons for anticing prompt and fruitful action. The position of many of itself supplies a practical incentive for peration and integrated effort in Western Europe. hough Dr. Adenauer has disclaimed any intention xploiting the military uses of nuclear energy or naking nuclear weapons, it is not to be expected Western Germany, with its record in scientific arch and development, will play no part in this field of human endeavour now being opened up. y by an integrated scheme in which all share the k, use the results and are aware of what is being e, can Germany participate without arousing the s and jealousies of her neighbours.

should also be remembered that in a new field nuclear energy, there are no established interests hinder development and demand reconciliation adjustment. Great Britain, moreover, has a ial interest in bringing about a Western European lear organization. The division of labour alone, time when on all sides we learn of the limitations h the shortage of scientific and technical skill es on the development of nuclear power, is itself fficient reason for Britain participating as actively a communal European programme as in the European Organization for Nuclear Research at Geneva. There are also the sharing of benefits in development, the diffusion of prosperity in building up a gigantic new industry. The tributes paid by Sir Francis Simon and others to the great ability, enterprise and vision of the team which Britain possesses in the Atomic Energy Authority all reinforce the suggestion that the British Government would be wise to take the initiative and offer active assistance from the start in bringing such a nuclear community into existence.

The nature and degree of British participation and assistance are open to consideration and for definition in advance. They may well fall short of full participation, while providing the leadership and initiative that British technical achievements warrant; and the commitments must be carefully weighed, particularly in respect of the demand which they will make for trained scientific and technical man-power.

That demand requires evaluation with imagination and realism, keeping in mind the competitive demands for man-power made by other aspects of Britain's economy—including fuel, as Prof. Hawthorne indicated—and also considerations of economics and prestige. A bold grasp of the export opportunities for Britain in the field of nuclear energy would seem imperative. In regard to man-power, the uniformity with which the limitations due to shortage of skilled personnel has been reiterated is impressive. In his statement on June 13 in the debate on the Queen's Speech, Mr. Geoffrey Lloyd was emphatic that such limitations, rather than financial considerations, determine the pace at which the Government is expanding its programme, and on July 20 he said explicitly that progress depends upon the mental outlook of the scientists, engineers and designers with the necessary skill in this special sphere, who are numbered in hundreds rather than in the thousands required. This admission was taken up by Mr. Austen Albu in opening an adjournment debate in the House of Commons on scientific and technical man-power during the following day; but the same point was stressed both by Prof. Hawthorne and Sir Francis Simon. Prof. Hawthorne, while emphasizing the need for more technologists, gave a specific warning against sending too many able young engineers to Harwell for training in nuclear engineering lest the technological man-power available for other new developments be decreased excessively, although he admitted that advances in one branch of engineering stimulate advances in all the others.

Sir Francis Simon is no less emphatic as to the great need to increase the supply of men who are able to practise science and technology, either for the development of nuclear energy or any other form of energy. The key role in all these developments falls to scientists and technologists, and Sir Francis in his article in *Lloyds Bank Review* stresses particularly the importance of building up a sufficiently strong and balanced community of scientists and technologists. It is not enough for sufficient support to be provided for research in nuclear physics. Other fields of physics, chemistry and the engineering sciences are all equally important in the development of nuclear power; and quite apart from the importance of other fields of technology to Britain's economy, the development of nuclear power is itself affected by our failure to provide adequately for road and rail transport development and to deal with the scientific and technical man-power situation with vision and imagination as well as with energy and adequate finance.

If the great opportunities which the development of nuclear power offers to Britain are to be used effectively, more will be required than what Mr. Lloyd described on June 13 as a 'shop window' at the Geneva Conference. The Government must give a positive lead, and make sure that, although the country is not in a position to offer nuclear fuel to the under-developed countries in the way that the United States can, the world is left in no doubt as to the value of the contribution in plant and technique which Britain can offer. Moreover, the absence of any such restricting legislation as the McMahon Act makes it easier for us to share our knowledge and experience than for the United States; and neither Europe nor the countries in the Colombo Plan should be left unaware of the benefits which Britain can bring them, or her advantage over the United States in this respect.

In all this, something of prestige is at stake, but much more also. For Britain to take full advantage of the possibilities for her economic future which nuclear energy offers, the Government must support the Atomic Energy Authority with a well-thought-out and comprehensive policy; it must be fully alive to what is involved in the way of educational policy and balanced scientific and technological development. It means tackling the problem of science teachers with energy and imagination. It means a programme for the expansion of technological and technical education, and keeping that expansion in balance with the expansion of university education. It means also close attention to secondary education, so that the supply of school leavers of the appropriate and broad education is to be forthcoming. It means attention to the nation's resources in scientific and technical research, and seeing that the development of natural resources as well as those of the public services is kept in balance.

Something of the challenge of the situation is to be glimpsed in Sir Francis Simon's article. Already Britain possesses in the Advisory Council on Scientific Policy and in other bodies much of the organization required. Some changes, however, may well be required, for example, in the responsibilities for university and technological and technical education, as between the Minister of Education, the Lord President of the Council and the University Grants Committee; and if the opportunities are to be used, there is much work to be done by the voluntary bodies. It can at least be hoped that the International Conference on the Peaceful Uses of Nuclear Energy will bring home to professional bodies generally the great opportunities which such developments hold for Britain's economic future, and that they will neglect no opportunity of securing the energetic and imaginative action which the prospect demands.

# MAGNETODYNAMIC COSMOGONY

## On the Origin of the Solar System

By Prof. H. Alfvén. (The International Series
Monographs on Physics.) Pp. vi+194. (Oxfo
Clarendon Press; London: Oxford University Pr
1954.) 30s. net.

THE author is presenting here a new theory
the establishment and evolution of the sc
system. He is well known for his contributions
electro- and magneto-dynamics, and he makes su
processes play a major part here, too. The book
a very valuable source of suggestions of subtle p
cesses that may be of relevance to this and ot
problems; and it serves to remind that a wide ra
of complicated electromagnetic effects may have
be understood for the solution of many astronomi
problems. If the discussion is uncertain and spe
lative for including such effects, others are
leaving them out. No criticism should attach to th

But if the work is to be regarded as a compl
theory of the derivation of the solar system, and t
is clearly what the author intends, then each one
the chain of processes or events would have to
shown to have at least a high degree of plausibili
This has not been accomplished. A major link in t
chain concerns the separation by diffusion of t
different constituents of a gas cloud. It is suggest
that a large cloud ($10^{17}$ cm.) is suspended agai
solar gravity by a magnetic field, and a very stro
dipole moment of the early Sun is assumed. T
gravitational force would then act on the no
ionized constituent, and this would diffuse inwa
relative to the ionized component which would
magnetically held. Late in the book there is a br
mention of the importance of the linkage of the li
of force, stating that the lines of force necessary
support the gas against gravity must not link t
cloud and the Sun. Indeed, this is a vital point,
a field of solar origin must inevitably link the Su
it cannot then support the cloud but only sligh
delay its infall by re-routing the material alo
longer paths. But the diffusive separation requi
some $10^8$ years and therefore a high stability of t
configuration. It is hard to see why the solar fi
was introduced in that discussion. An alternati
support is briefly mentioned; this is a magnetic fi
of interstellar clouds of gas. Such a field will not li
the Sun, and could, if of adequate strength, give t
desired support. But it can do so only if its lines
force are effectively anchored in gas far away a
unaffected by the solar gravitation. But by linki
the gas to interstellar material one is even furth
from any possibility of extreme stability with
motion of less than $10^{17}$ cm. in $10^8$ years. The avera
velocities between stars and gas clouds are $10^4$
$10^5$ times as high. Not only is the requirement n
obtained in this way, but indeed it is hard to see h
an extended gaseous mass surrounding the Sun co
resist the interstellar streams, even if it is not ma
netically connected to them.

There are other links in the chain of processes th
one would like to see more fully discussed. T
mechanism of transfer of angular momentum to
disk surrounding the Sun has long featured as
central problem in the subject; it may be that
magnetic interaction with the Sun is responsible, b
the process will have to be understood, and the lin
of its effectiveness evaluated.

THOMAS GOLD

# THE STATISTICS OF CHANGE

Introduction to Stochastic Processes, with Special Reference to Methods and Applications
Prof. M. S. Bartlett. Pp. xiv+312. (Cambridge: the University Press, 1955.) 35s. net.

HE theory of stochastic processes is the mathematics of systems which change in accordance h probability laws. There are many applications for example, to the study of epidemics, cosmic ray wers, irregularities in textile processing, queueing d storage problems, the growth and mutation of terial populations, and communication theory. of. M. S. Bartlett has made distinguished con- butions to many branches of the theory, and now has produced this masterly introduction to the ole field. He writes as a statistician and applied thematician and is therefore thoroughly justified avoiding detailed discussion of various matters, uch, while of considerable mathematical interest, n easily divert attention from the aspects of most portance in applications. The result is that he has en able to cover concisely a remarkable range of thods and problems and that, while the book is ghly mathematical, the mathematics is always ected towards obtaining a working answer to the blems under discussion. The pure mathematical pects of stochastic processes have been dealt with a recent book by J. L. Doob ; the point of view the two books is entirely different, and Prof. rtlett's is the only one at present available for the re applied worker in this field.

After a preliminary chapter devoted to basic finitions and to recalling some results in prob- ility theory, there is a chapter on random walks d Markov chains occurring in 'discrete time' ; one the applications described is to the statistical chanics of nearest-neighbour systems. There is xt a chapter on the corresponding processes in tinuous time. Particularly noteworthy here is discussion of passage and recurrence time prob- ns, based on an elegant symbolism for determining Laplace transforms, or probability generating ctions, of the distributions of the times taken for cified types of transition to occur. This section the book is completed by a long chapter on mis- laneous applications. The topics discussed here lude population growth and epidemic models.

The next group of chapters deals with stationary cesses, that is, systems which are in statistical ilibrium. After a preliminary chapter, there is an count of the spectral function and of the generalized monic analysis of stationary processes. This is lowed by a discussion of recurrence times and, ong other things, a brief account of applications the theory of turbulence. The third chapter of this up deals with prediction and communication theory. The final two chapters discuss problems of tistical inference connected with stochastic pro- ses, the last chapter being about the correlation d spectral analysis of stationary time-series. This thers together in a valuable way recent work on s subject. The emphasis is on situations where the ject of the statistical analysis is to examine the ucture of the observed process. It would have en interesting to have had also some discussion of er applications, for example, to problems of npling, where the precise structure of the process not the point at issue. It might also have been pful to have had some mention of processes which, while stationary, show appreciably greater long-term fluctuations than processes usually considered in the theory. An example is when the spectral density behaves like $\omega^{-\alpha}$, $0 < \alpha < 1$ as $\omega$ tends to zero. This seems to happen in some applications, for example, in certain textile problems where there are sources of random irregularities with very long wave-lengths.

The presentation is open to minor criticism. In detail the writing, though clear, is very concise, and the book is not easy reading. Some familiarity seems desirable with the elementary parts of the subject (such as those given in the book by W. Feller); results for simple processes are almost always obtained as special cases of general formulæ, rather than used for preliminary illustration of the ideas involved, as would, perhaps, have been advisable in an introductory work. Also, the assumptions for special applications are occasionally set out only in symbolic form. This will cause no difficulty to anyone reading the book systematically, but is hard on the reader who wishes just to find out what is assumed in the discussion of some particular application of interest. However, the book is a characteristically original, impressive and important contribution to the subject, and deserves to be widely read.

# MEASUREMENT AND AUTOMATIC CONTROL

Instrument Engineering
(McGraw-Hill Publications in Aeronautical Science.) By Charles Stark Draper, Prof. Walter McKay and Prof. Sidney Lees. Vol. 1: Methods for Describing the Situations of Instrument Engineering. Pp. xvi+269; 51s. Vol. 2: Methods for Associating Mathematical Solutions with Common Forms. Pp. xxviii+827; 120s.
(London: McGraw-Hill Publishing Company, Ltd., 1952, 1953.)

THESE volumes are out of the ordinary, both in magnitude and in presentation of the subject-matter. They are the first two of three volumes—the third is not yet available—which combine the functions of introductory text-book and comprehensive reference book of mathematical techniques relating to "the art and science by which the properties of matter and the laws of nature are made useful to man in the observation and control of physical processes".

The authors are members of the Aeronautical Engineering Department of the Massachusetts Institute of Technology, and these books are the outcome of twenty years experience in research and postgraduate teaching in the field of aircraft instrumentation and control. This background has largely influenced the presentation of the subject-matter, and made possible the accumulation of the very large number of most useful results of mathematical analysis which are now made more widely available.

The need to find a common language and symbolism for mathematicians, physicists and a diversity of engineers—aeronautical, electrical and mechanical—in a field to which all have combined to contribute has led the authors to devise an elaborate, but most carefully defined, nomenclature and symbolism, which are used throughout the volumes. This leads, however, to such distressingly cumbersome statements as: ". . . it appears that, from the standpoint of physical fact, the ***ith to kth actuating input function product–reference input function product performance function ratio function*** reduces to the ratio of the reference input function product to the ith to kth input function product" (Vol. 1, p. 134). Even the corresponding mathematical statement is little shorter, because of the use of "self-defining symbols" in the statement of general relations. A simple example is sufficient to indicate their form and use: the standard deviation of $x$ is given by $(SD)x \equiv (\boldsymbol{RMS})\,[(D)\,x]$, in which $(D)x \equiv x - (Av)x$ (Vol. 1, p. 148). The authors, of course, accept the use of "working variable symbols" in deriving results, but consider that all results other than those derived for purely educational purposes should be formulated finally in terms of "self-defining symbols" (Vol. 1, p. 109), and they conform rigidly to this practice.

When the reader has overcome the initial difficulties of interpretation—the difficulties of translation even from American to English terminology (for example, fitting constant (FC) ≡ constant of integration) give one especial sympathy for the non-English-speaking reader—there are available in these volumes a most thorough exposition of a rigorously systematized way of analysing physical systems mathematically (Vol. 1), and analytical, graphical and numerical methods for deriving the solutions of the resulting differential equations, with—perhaps the most valuable feature of the work to the British engineer—nearly two hundred clearly reproduced large-scale graphs presenting data concerning every aspect of these solutions (Vol. 2). There are, also, in Vol. 1 useful introductions to dimensional analysis and statistical methods, and in Vol. 2 a chapter on the analysis of second-order discontinuous systems, having "non-linear terms of the rate-determined step type", due, for example, to the effect of Coulomb friction or of relay-operated controlling devices.

To sum up, these volumes are most welcome publications, in making generally available the very thorough exposition and useful graphs which have previously only been available locally. Because of the language and notation it seems unlikely that they will be considered suitable for teaching purposes on the eastern side of the Atlantic, but as reference books they are likely to prove of lasting value and should be available in every library of books on instrumentation and control engineering.

G. D. S. MacLellan

# MAMMALIAN BIOCHEMISTRY

## Principles of Biochemistry

By Prof. Abraham White, Prof. Philip Handler, Prof. Emil L. Smith and Dr. DeWitt Stetten. Pp. xiii + 1117. (London: McGraw-Hill Publishing Company, Ltd., 1954.) 112*s.* 6*d.*

THIS book is described on the dust-cover as "an integrated presentation of fundamentals". It might at first sight be doubted whether, with four authors at work, much integration could be achieved; but in fact they have succeeded so well that it is worth mentioning how they went about writing the book. The first draft of each chapter was assigned to one of the four authors and, when completed, was criticized by the other three. They met regularly for such discussions for several days at a time, and in some instances a chapter written by one of them was rewritten by another. In the end, each author had contributed to each chapter. As a result, this book shows none of the overlapping or lack of c tinuity of style or matter which is so often found a book by several authors.

The subject is treated in seven sections which d in turn with the chemical composition of the ce the enzymes, intermediary metabolism, the bo fluids, specialized tissues, the hormones and nutriti Intermediary metabolism is introduced by a valua chapter on the general methods used in investigat metabolism—experiments on whole animals, isolated organs and on tissue preparations, the stu of patients with inborn errors of metabolism, the of isotopes as tracers, and so on. The last secti nutrition, is at first sight surprisingly brief for a bo of this size; but clearly so many topics bear on nutrition have already been covered earlier the book—vitamin A under the lipids and under biochemistry of the eye, various members of vitamin B complex under individual coenzymes, so on—that there is correspondingly less remain to be dealt with in the nutrition section. All same, a chapter of one and a half pages on chemi elements in nutrition does seem almost ludicrou short. This tendency towards the curtailing of top considered under nutrition will presumably conti as more and more becomes known of the prec biochemical function of the vitamins. In books theoretical biochemistry, the vitamins will tend be dealt with separately in connexion with metabolic reactions which they influence rather th as a heterogeneous group of organic compounds wh the body needs but cannot make. But the vitam are closely linked by the early history of their covery and investigation, and it will be a great p if in the text-books this history gets lost sight of a mass of details of chemical reactions and spec catalysts.

The style of writing throughout the book scholarly and clear, and it is evident that the auth are writing from a wide experience of teaching. T book is well produced, with the structural formu and chemical equations admirably set out. There occasional slips or misprints (for example, in structural formulæ of the nucleosides and nucleoti on pp. 186–188, where the groups attached to sugar rings should all be inverted), but these are and far between. The book relies largely for figures on reproductions from published work, on the whole these have not been adequat assimilated into the text. For explanation of figures the reader is almost entirely dependent the smaller-print legends; these are sometimes almost telegraphic brevity, and it would have m for easier reading if there had been a little m comment on the figures in the main part of the te

While the book is mainly on mammalian b chemistry, it deals to some extent with comparat biochemistry, and there are frequent references the biochemistry of micro-organisms and plants. example, the chapter on carbohydrate metabol begins, very reasonably, with an outline of the p cesses of photosynthesis. The references at the e of the chapters, many of them to books and rev articles, are well chosen, up to date and by no me confined to American publications. For und graduate medical students, in any event in Brit this book will probably be considered too large too costly. For science students and for those enga in teaching and research, it will be welcomed a stimulating and a well-written text-book.

D. C. Harriso

# CURARE ALKALOIDS*

By Prof. P. KARRER, For.Mem.R.S.
Chemical Institute, University of Zurich

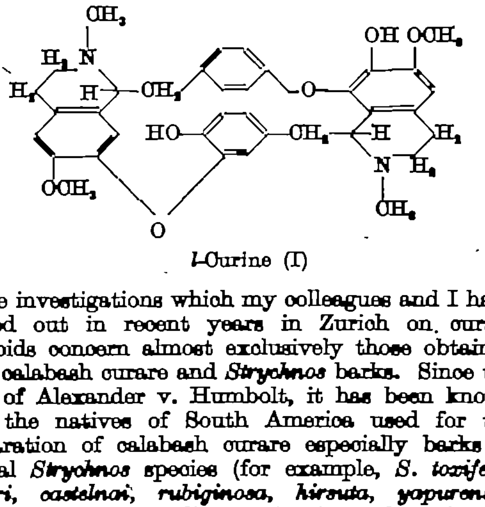
ARROW poisons have been known for centuries and have been used in certain regions of Africa, Asia, South America and also Europe. The African and Asiatic poisons are almost exclusively of a glucoside nature. In certain Asiatic countries the commonest and most important arrow poison is made from the latex of *Antiaris toxifera*, a member of the Moraceae, which contains the glucosides α- and β-antiarine; in Africa it is very often made from one of the Apocynaceae, *Acokanthera*, the toxic principle of which is the glucoside ouabain. In Europe, from prehistoric times until about the fifteenth century, it is possible that extracts of species of aconite, *Veratrum album*, snake poisons, etc., were used as arrow poisons. The toxic principle of the South American arrow poisons is alkaloids; this poison is called curare and its alkaloids curare alkaloids.

Three different kinds of South American curare are known: pot-curare, tubocurare and calabash curare. They not only differ in their containers (unglazed clay pots, bamboo tubes and calabashes or gourds), but also in the nature of their active principles and in their toxicity. The calabash curare is by far the most toxic, and therefore the most desirable one but also the most difficult one to obtain.

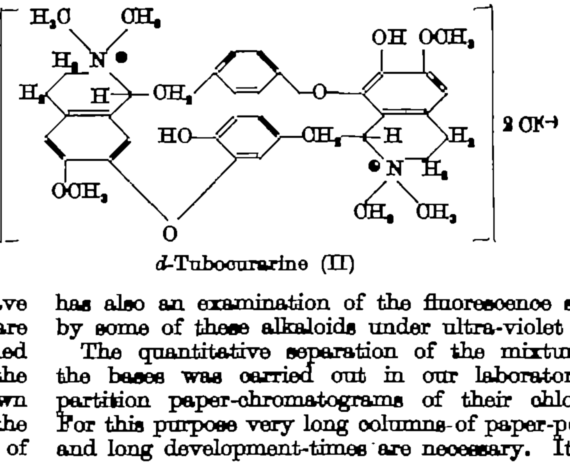
Wintersteiner introduced *d*-tubocurarine in medicine and it is still the only natural curare alkaloid used for clinical purposes. Its commercial name is 'Intocostrine'. The activity and toxicity of *d*-tubocurarine appear to be low compared with those of certain calabash alkaloids.

The most important and most active South American arrow poison, the calabash curare, has for the frog a toxicity of 0·5–1 mgm. per kgm. The first chemical work on this arrow poison dates back to the pharmacologist Böhm. However, it was not until 1937–41 that H. Wieland and his co-workers were able to isolate for the first time some pure alkaloids in a crystalline form.

The calabash curare usually contains a very great number of different alkaloids. In a sample originating from the Rio Negro region, we were able to demonstrate by paper chromatograms the occurrence of more than thirty different bases. For distinguishing the different spots on the paper chromatograms, we have used the colour reactions with ceric sulphate, which gives with the different alkaloids, red, blue, yellow, green, purple or yellowish-green colours. Furthermore, colour tests with cinnamic aldehyde, nitric acid and sulphuric acid have been made, as has also an examination of the fluorescence shown by some of these alkaloids under ultra-violet light.



*l*-Curine (I)



*d*-Tubocurarine (II)

The investigations which my colleagues and I have carried out in recent years in Zurich on curare alkaloids concern almost exclusively those obtained from calabash curare and *Strychnos* barks. Since the time of Alexander v. Humbolt, it has been known that the natives of South America used for the preparation of calabash curare especially barks of several *Strychnos* species (for example, *S. toxifera*, *jubleri*, *castelnai*, *rubiginosa*, *hirsuta*, *yapurensis*, *triplinervia*, *curare baillon*, etc.). A number of other plants, which are admixed when curare is prepared (*Cocculus* species, Menispermaceae, Araceae, Euphorbiaceae), seem to contribute nothing or very little to the toxicity of the poison.

From tubocurare and pot-curare some di-*iso*quinoline-alkaloids have been isolated which have the character of di-tertiary bases or di-quaternary salts. Examples are *l*-curine (= *l*-bebeerine) and *d*-tubocurarine; the first has the character of a tertiary base, the latter is a di-quaternary di-*iso*quinolinium-salt. For the preparation of tubocurare, and pot-curare probably especially, *Chondrodendrum* species are used, in the barks of which in some cases the same alkaloids occur as those found in the above-mentioned kinds of curare.

The quantitative separation of the mixtures of the bases was carried out in our laboratory by partition paper-chromatograms of their chlorides. For this purpose very long columns of paper-powder and long development-times are necessary. It took more than a year to separate twenty-three alkaloids of the above-mentioned mixture in pure crystalline form. The chemical composition of these substances is very similar, as can be seen from the following formulæ:

| | | $R_c$* | | | $R_c$* |
|---|---|---|---|---|---|
| C-alkaloid *A* | $C_{20}H_{25}O_2N_2^+$ | 0·23 | C-dihydrotoxiferine | $C_{20}H_{23}N_2^+$ | 1·22 |

$$* R_c = \frac{\text{distance travelled by the alkaloid}}{\text{distance travelled by curarine}}$$

Solvent = methyl ethyl ketone saturated with water + 1–3 per cent methanol

---

* Substance of two lectures delivered in the University of London School of Pharmacy) on March 10 and 11.

From calabashes of different origin we were able to isolate other new alkaloids, and also from barks of several *Strychnos* species (*mitscherlichii*, *toxifera*, *melinoniana*) new bases of this group have been obtained; most of them have the character of quaternary salts, but some are tertiary bases. Up to date, the following pure calabash- and *Strychnos*-bark alkaloids are known:

* + C-curarine I (refs. 2, 8, 9, 10)
* C-curarine II (ref. 3) (C-strychnotoxine I*a*) (ref. 11)
* + C-curarine III = C-fluorocurarine (refs. 3, 8, 9, 10)
* + C-toxiferine I = toxiferine I (refs. 1, 4, 6, 8, 9, 17)
* + C-toxiferine II = C-calebassine (refs. 4, 5, 8, 9, 10, 17) (= C-strychnotoxine I)
* + toxiferine II (ref. 4) (= strychnotoxine II (ref. 11)
* C-dihydrotoxiferine I = C-alkaloid *K* (refs. 4, 8, 9)
* C-isodihydrotoxiferine (ref. 4)
* + C-alkaloid *A* (refs. 5, 8, 9, 10)
* + C-alkaloid *B* (refs. 5, 8, 9, 10)
* + C-alkaloid *C* (refs. 8, 9, 10)
* C-alkaloid *D* (refs. 8, 9)
* C-alkaloid *E* (refs. 8, 9)
* C-alkaloid *F* (refs. 8, 9)
* C-alkaloid *G* (refs. 8, 9)
* C-alkaloid *H* (refs. 8, 9)
* C-alkaloid *J* (refs. 8, 9)
* C-alkaloid *L* (refs. 8, 9)
* C-alkaloid *M* (ref. 13)
* C-alkaloid *O* (ref. 12)
* C-alkaloid *P* (ref. 12)
* C-alkaloid *UB* (refs. 7, 8, 9)
* + C-alkaloid *Y* (refs. 5, 13)
* C-alkaloid *X* (refs. 7, 8, 9)
* C-calebassinine (refs. 8, 9)
* + C-fluorocurine (refs. 8, 9 14)
* + C-fluorocurinine (refs. 8, 9, 10)
* + C-mavacurine (refs. 11, 14)
* C-xanthocurine (ref. 12)
* + C-guaianin (ref. 12)
* + C-alkaloid I (refs. 8, 9, 10)
* C-alkaloid 1 (ref. 11)
* C-alkaloid 2 (ref. 11)
+ fedamazine (ref. 14)
+ caracurine I (ref. 14)
+ caracurine II (ref. 14)
+ caracurine III (ref. 14)
+ caracurine IV (ref. 14)
+ caracurine V (ref. 14)
+ caracurine VI (ref. 14)
+ caracurine VII (ref. 14)
+ caracurine VIII (ref. 15)
+ caracurine IX (ref. 15)
+ nordihydrotoxiferine (ref. 15)
+ melinonine *A* (ref. 16) (= tetrahydroalstonine-chlormethylate)
+ melinonine *B* (ref. 16)
+ "toxiferines III to XII" of H. King (ref. 17) (homogeneousness not proved)

* = alkaloids found in calabashes.
+ = alkaloids found in barks of *Strychnos* species.

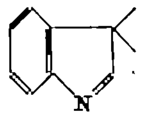
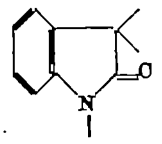
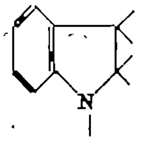
The ultra-violet spectra of the calabash- and *Strychnos*-bark alkaloids show that most of these compounds are indole derivatives. It is possible to divide them into about eight groups, which probably possess the following chromophores:



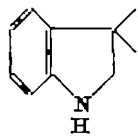
C-Curarine
C-Alkaloids *G* and *E*
C-Guaianine
Caracurine V



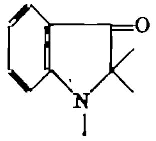
C-Toxiferine
C-Dihydrotoxiferine
C-Alkaloids *H* and 2
Caracurine VI



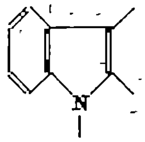
C-Alkaloids *A*, *F*
I, II, X, Y
Caracurine IV and VII (?)



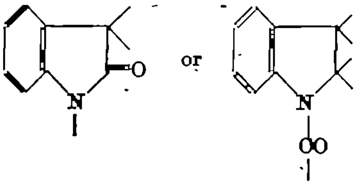
C-Alkaloids *B*, *C*, *D*
Caracurine II and III



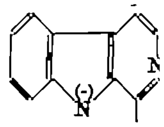
C-Fluorocurine
C-Fluorocurinine



C-Alkaloids *J*, *L*, I
C-Mavacurine
Toxiferine III
Melinonine *B*



Calebassinine
C-Alkaloids *UB* and *M*



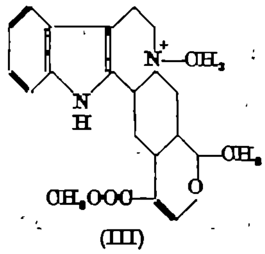
C-Xanthocurine
Fedamazine

The elucidation of the constitution of the calabas and *Strychnos* bark alkaloids is an objective whic still lies in a rather distant future. Some fir degradation experiments on calabash alkaloids wer conducted by Wieland and his co-workers. B dehydration reactions on dihydrotoxiferine I, the succeeded in obtaining β-ethylindole and *iso*chinolin whereas from C-toxiferine II some β-ethylpyridir was obtained; they suggested the presence of *is* chinoline—or chinoline—or indole-rings in C-curarin

We were able to get by distillation with zinc du from C-norcurarine, which itself had been obtained b thermal decomposition of the quaternary chloride C-curarine I, β-ethylpyridine, β-ethylindole, skatol carbazole and *l*-methylcarbazole.

The production of β-ethylindole after distillatio with zinc dust of norcurarin makes it probable tha C-curarine is, like many other plant bases, derive from tryptamine. The isolation of carbazole an *l*-methylcarbazole, however, excludes a constitutio based upon the harman type (yohimbine bases). The dehydrogenation products obtained indicate th relationship of C-curarine with the *Strychnos* alkaloid. Thus strychnine, on vigorous degradation, gav β-ethylindole, β-collidine and carbazole.

An alkaloid melinonine *A* (III), which E. Schlittle discovered in the bark of *Strychnos melinoniana* an which is without curare activity, has proved to b the chlormethylate of tetrahydroalstonine, an indol alkaloid the constitution of which was already known

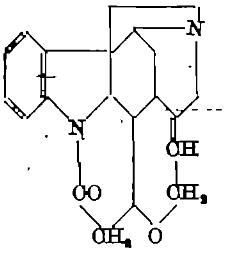


(III)

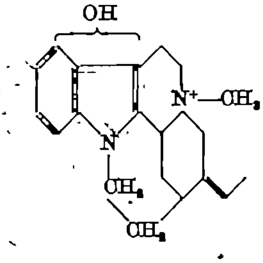
A thorough investigation of the two calabash kaloids fluorocurine and mavacurine in our labor-ory showed that between these two compounds, hich always occur together, interesting connexions :ist and it was possible to get an insight into their ructure.

The indoxyl derivative fluorocurine can be reduced 7 sodium borohydride to hydrofluorocurine, and the tter is easily transformed by acids into the indole rivative mavacurine. We have followed many gradation reactions which have enabled us to clear the constitution of these three alkaloids, with e exception of the position of one OH-group which ccurs in these compounds.

Hydrofluorocurine (V) readily undergoes the so-lled Emde degradation; that is, when subjected reduction with platinum and hydrogen in alcoholic lution, a carbon atom attached to the quaternary itrogen atom is split off; at the same time, hydro-nation of the C=C double bond of hydrofluoro-rine takes place. On degradation with chromic acid, e Emde base (VII) gave a methyl-ethyl-acetic acid X); this proves that the position of the side chain the hydrofluorocurine relative to the N(b)-atom of e compound corresponds to formula (V). The mde degradation of mavacurine (VI) leads to a bstance of the constitution (VIII), an indole



Strychnine

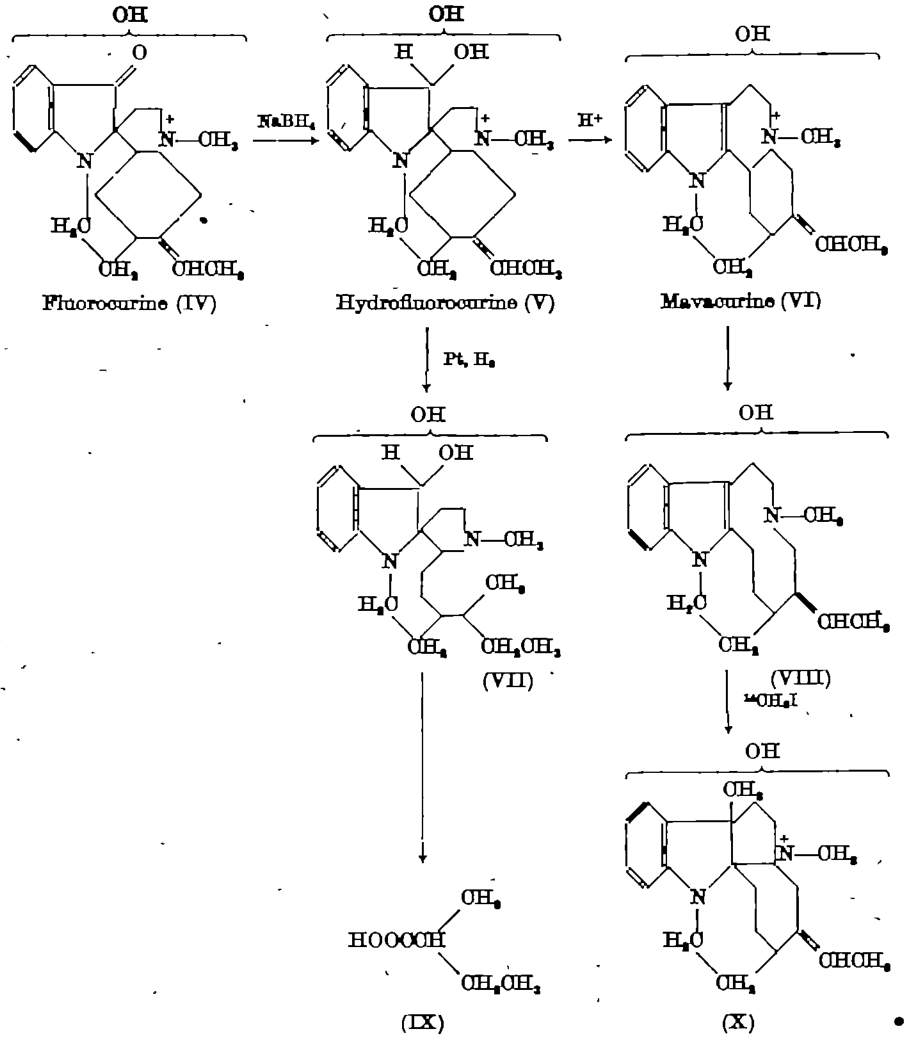


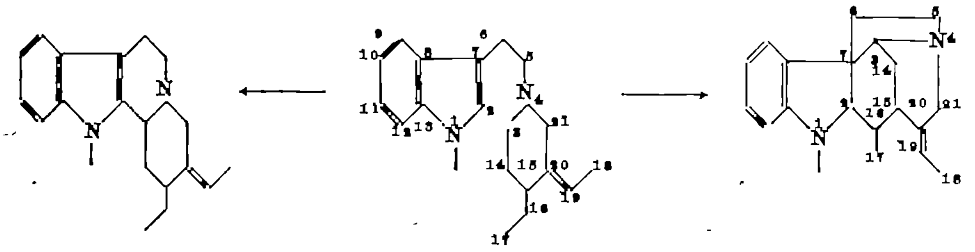
Mavacurine

derivative, which could be methylated by methyl-$^{14}$C iodide to an indoline derivative (X) containing a CH$_3$-group on the carbon atom 3. A number of other reactions of fluorocurine and mavacurine agree with the formulæ IV and VI proposed for these two alkaloids.

It is a remarkable fact that the carbon double bond which occurs in fluorocurine and mavacurine has the same position with regard to the N(b)-nitrogen atom of the two alkaloids as that in strychnine to the corresponding N(b)-atom.

Already Sir Robert Robinson and R. B. Woodward have pointed to possible genetic relationships between the yohimbine and strychnine alkaloids. If in the





(*B*) (*A*) (*C*)

hypothetical substance *A* a bond between the two carbon atoms 2 and 3 is formed, a compound *B* of the β-carboline or yohimbine type arises. But if in substance *A* the carbon atoms 3 and 7 on one side and the carbon atoms 2 and 16 on the other side are connected by bonds, a compound *C* of the strychnine type would be formed. Further investigations will show if type *C* is also realized among the curare alkaloids.

Formulæ *B* and *C* show very clearly the identical position of the carbon double bond in mavacurine and fluorocurine on one hand and of strychnine on the other.

During recent years compounds with curare activity have aroused great medical interest; they find practical application in surgery during anæsthesia, causing complete relaxation of the muscle, thereby enabling the quantity of the anæsthetic to be reduced. For practical purposes *d*-tubocurarine ('Intocostrine') especially is used, and to a limited extent also synthetic compounds. For many of these synthetic substances the formula of *d*-tubocurarine, which contains two quaternary ammonium salt groups, served as a model. But the halogen alkylates of strychnidine and dihydrostrychnidine which hav been investigated in our laboratory contain, like th calabash alkaloids, only one quaternary ammoniu salt group and are about as toxic and as active 'Intocostrine'. I have already mentioned that som calabash alkaloids, for example C-curarine, a probably related to strychnine with regard to the constitution. It is true that the curare activity the halogen alkylates of strychnidine is about hundred times less than that of C-curarine and abo three hundred times smaller than that of the calabas alkaloid C-toxiferine I.

With their lethal doses of about 1–8γ per kgn for mice, the calabash alkaloids *F* and *G* belong the most toxic substances which are known to-da 1 gm. of these compounds would paralyse at least hundred tons of mice.

A group of colleagues and pupils of mine pa ticipated in the investigations on calabash curare I mention particularly Prof. H. Schmid, who too part in these investigations from their beginnin and Dr. P. Waser, Dr. A. Ebnöther, Dr. J. Kebrl Dr. H. Asmis, Dr. H. Bickel, Miss Bächli and E Meyer.

---

# AN ATOMIC STANDARD OF FREQUENCY AND TIME INTERVAL

## A Cæsium Resonator

A FREQUENCY standard (Fig. 1) based on a natural resonant frequency of the cæsium atom has been constructed at the National Physical Laboratory and used for calibrating the quartz clock standards with an accuracy of ± 1 part in $10^9$ (0·0001 sec. per day). It makes use of the atomic beam magnetic resonance technique developed by Rabi and his collaborators[1].

The resonance observed is that due to transitions between the hyperfine structure energy-levels caused by the interaction between the nuclear and electron spins. For observational purposes a uniform magnetic field is applied so that these energy-levels are split into their Zeeman components. The frequency of the central line of the Zeeman pattern is, however, to the first order, independent of the value of the field, being given by[2,3]

$$\nu = \nu_0 + 427 H^2,$$

where $H$ is the field in oersteds and $\nu_0$, which is approximately $9\,192 \times 10^6$ c./s., is a fundamental constant of the atom. The frequencies of the other lines have a much larger, linear dependence on the field and provide a convenient means of definin its effective value.

All the allowed transitions have been observe and from measurements made under a variety conditions the frequency of the central line zero field was found to be 9 192 631 830 ± 10 c./ in terms of the present adopted frequency of th quartz standard, which is based on a provision uniform time-scale[4] estimated by the Royal Greer wich Observatory. The sharpness of the reso ance is indicated in Fig. 2, which is typical the resonance curves we have obtained. As, i practice, the observations are made in the presen of a small uniform field, it may be convenient t define the standard as the frequency of the centr line at a specified field. We propose to use the val obtained when the field is adjusted to make th frequency of the adjacent (3·1–4·1) line exact 500 kc./s. higher than that of the central line becaus by such a procedure, the difficult measurement effective field is replaced by a simple frequen measurement. The frequency of the central line f this condition is 9 192 632 050 ± 10 c./s. Th potential precision of the cæsium standard at th National Physical Laboratory is considerably highe than the 1 part in $10^9$ at present claimed; but speci

Fig. 1. The atomic beam chamber supported on two pedestals, the oil diffusion pumps, and the coils for producing the appropriate d.c. field. The radio-frequency field for exciting the resonance is applied to two cavity resonators, which are coupled to an oscillator by means of the waveguide feeds on the top of the beam chamber

lectronic techniques will have to be developed before his higher precision can be utilized. The accuracy iven is that which has already been achieved and hich can be used with our existing quartz standards nd techniques of frequency measurement[5,6].

The apparatus is designed to enable many of the arameters to be varied through a wide range so hat any effect of such variations on the observed esonant frequencies can be studied. When the ermissible tolerances have been determined, a simpler nodel can be designed. During this investigation the pparatus will be used for periodic checks on the requency of the quartz clock which constitutes our vorking standard of frequency and time-interval. A omparison between these results and the values lerived from the unit of Universal Time should give nteresting information concerning the variations of he period of rotation of the Earth, which are known o be of the order of 1 part in $10^{8}$ and which at present imit the accuracy of frequency standardization. It has een suggested that Ephemeris Time[7], which is based n the sidereal year, should be used for eliminating he variations in the length of the day. The unit of ime in this system can be given with the required recision only some years in retrospect, although it s hoped[8] by means of observations of the Moon at a number of observatories to reduce this delay to one year. Whatever system is used, an astronomical unit of time accurate to 1 part in $10^{9}$ will be at least one year in arrears and will, of course, be an average value over that period. The great advantage of an atomic standard is that it enables the frequency standardization to be effected by measurements lasting only a few minutes. The value thus determined can be made available throughout a large area of the world by means of standard frequency transmissions[9,10].

The pioneer work on atomic standards of frequency has been carried out in the United States, and before starting this work one of the authors had many helpful discussions, in particular with Dr. H. Lyons and Profs. P. Kusch, C. H. Townes and J. R. Zacharias. Lyons[3] built a cæsium standard at the National Bureau of Standards, Washington, D.C., and obtained a value of 9 192·632 Mc./s. for the frequency of the central line. Later he has used the Ramsey method of excitation, as used in this experiment, giving a much sharper resonance, but has not published any results so far as we are aware. More recently, Zacharias, Yates and Haun[11] have described a somewhat different cæsium beam apparatus, and Townes[12] has described an oscillator based on a transition in the ammonia molecule; but in neither case are absolute values of frequency given. The results reported here appear, therefore, to be the

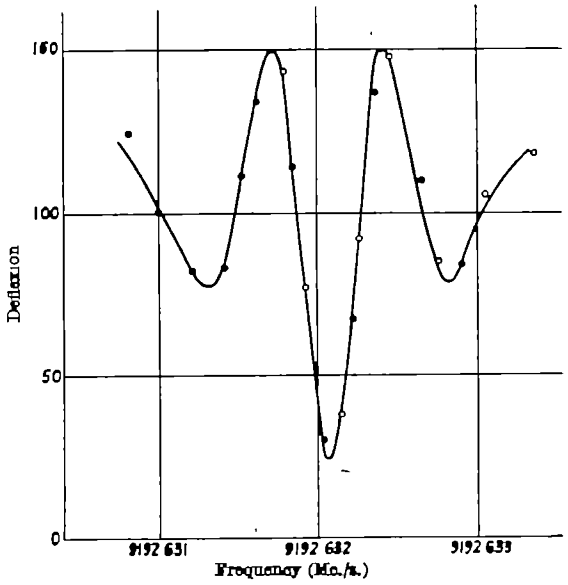

Fig. 2. Plot of the 3 0–4 0 transition in cæsium. Zero on the meter deflexion is arbitrary, the resonance dip being about ⅓ of the total beam current

first examples of the use of an atomic frequency standard with an accuracy greater than that obtained by using a unit of astronomical time. They also represent the highest accuracy ever achieved in the measurement of any physical quantity in terms of a definitive standard.

## Definition of the Second of Time

THE preceding communication by Essen and Parry describes a means by which frequencies and intervals of time may be measured with an accuracy of 1 in $10^9$, and holds out a prospect of even higher accuracies.

Ephemeris Time, on which the definition of the second adopted by the International Astronomical Union and the International Committee of Weights and Measures depends, is derived from the motion of the Moon. If the position of the Moon at any time can be determined to 0·05 sec., a period of four years would be necessary to obtain an accuracy of 1 in $10^9$ in time and frequency derived from astronomical observation. Essen and Parry mention Markowitz's proposals for reducing this period to one year; these depend on a reduction of the errors by repetition of observations. Such a reduction would involve a study of systematic errors in star places and in the corrections for differential refraction that would certainly take many years. During this time the atomic clocks will be improved, probably by a greater factor than the astronomical determinations.

It thus seems probable that for the foreseeable future the accuracy of the measurement of frequency and of time intervals relative to laboratory standards will exceed that by astronomical means, and that the astronomically defined second is therefore incapable of realization with the accuracy necessary for microwave spectroscopy. The natural way of escape from this difficulty is to define a 'physical second' in terms of the natural period of the cæsium atom, choosing the numerical value so that it agrees as well as may be with the current estimates of the second of Ephemeris Time. Experience of the working of the machinery for obtaining international agreement on such matters suggests that some years are likely to elapse before a decision could be reached. The purpose of the present communication is to solicit views on the desirability of abandoning the astronomical second for the most refined physical measurements and to encourage other suitably equipped laboratories to make determinations of the cæsium frequency of the highest accuracy.

It is possible that the new accuracy in the measurement of frequency will reveal some unexpected phenomena. It is not self-evident that the tim shown by atomic and astronomical clocks will kee in step indefinitely. In fact, Dirac, Milne, Jorda and others have suggested that what are usuall regarded as the 'constants of physics' may chan by amounts of the order of $1/T$ per year, where $T$ the 'age of the universe' in years. If $T$ is abo $4 \times 10^9$ years, changes of this order may soon b measurable over intervals of a few years. This is matter that can only be settled by experiment an gives an added interest to the development of metho of precise time-keeping.

# EXPLORATION OF THE EARTH' UPPER ATMOSPHERE USING HIGH-ALTITUDE ROCKETS

## BRITISH RESEARCH PROGRAMME

### By SIR DAVID BRUNT, Sec.R.S.

THE wind, temperature, humidity and othe properties of the atmosphere up to heights c about twenty miles can be studied directly by mean of instruments carried up by free balloons. Observa tions of this kind are regularly made by meteorolo ical services throughout the world. Although th atmosphere at greater heights is very tenuous, i necessarily plays an important part in many phen omena. Thus long-distance radio propagation is onl possible because of the existence of reflecting layer the ionosphere, at altitudes of 60 miles and above—indeed, a very important region extends upward from a height of 90 miles. Meteors are mainl evaporated at the 60-mile level, and the aurora, a least in high latitudes, is located at about the sam level. The electric currents which give rise to th variations of the earth's magnetic field circulate i this region, and it is also the seat of a night-tim air-glow quite distinct from the aurora or the lig of moon and stars.

Before the Second World War, information abo the upper atmosphere could only be obtained b indirect methods. The remarkable developments c rockets as weapons led to the possibility of carryin instruments into the upper air in vehicles of this kin This was first achieved in the United States in 194 using captured V2 rockets. Since that time stead progress has been made and many interesting result have been obtained. The greatest height reache so far has been 240 miles.

A research programme of this kind is expensiv and until recently was exclusively carried out b American scientists and technicians. It is ver desirable that work should be carried out in othe countries, to obtain data under different conditio and locations and employing different technique A programme has already been commenced i France, and an extensive programme is now bein initiated in the United Kingdom through the co-opera tion of the Ministry of Supply, particularly the Roy Aircraft Establishment, and the Gassiot Committe of the Royal Society. The programme aims at havin available, within two years, rockets able to carr 100 lb. weight of scientific instruments up to height f 120 miles or more. The design, development, upply and firing of the rockets will be carried out by he Ministry of Supply. Five university research groups, from University College, London (Prof. S. W. Massey), the University of Birmingham Prof. J. Sayers), The Queen's University of Belfast Profs. D. R. Bates and K. G. Emeléus), University College, Swansea (Dr. W. J. G. Beynon) and the Imperial College of Science and Technology, London Prof. P. A. Sheppard), will be initial participants in he scientific programme. The work will be co-ordinated through a special sub-committee of the Gassiot Committee of the Royal Society. The first experiments will include determination of atmospheric emperature and density, the study of the nature of he ionosphere, a search for very fine meteoric dust below 60 miles altitude, and determination of the heights of the regions from which the night air-glow s strongest. While the development of the rockets s proceeding, work on the scientific instruments required will proceed in parallel, so that both should be available at nearly the same time.

Although this programme has been arranged independently of the International Geophysical Year, 1957–58, it is hoped that it will be in operation during this period and add substantially to the British contribution to the Year.

## OBITUARIES

### Sir Harold Tempany, C.M.G., C.B.E.

Sir Harold Tempany's forty-three years in the Colonial Agricultural Service (now called the Agricultural Branch of H.M. Overseas Civil Service) stretched a good way on either side of the great changes which followed on the Imperial Agricultural Conference of 1927. These gave the Service the beginnings of a unity, enlarged it in numbers and resources, provided training for its cadets and placed at its head an agricultural adviser to the Secretary of State for the Colonies. The late Sir Frank Stockdale was the first to fill this post (1929). Tempany joined him as assistant adviser in 1936 and, succeeding him in 1940, was in office during the hard years up to his retirement in 1946.

Variety in the earlier half of his career gave width to the knowledge of climates, soils, agriculture and administration on which his success in the diversified tasks of the latter half depended. Soon after graduating at University College, London, where chemistry, always central in his technical thinking, was his main study, he was appointed assistant agricultural chemist, Leeward Islands, in 1903, and a few years later chief chemist and superintendent of agriculture. In Mauritius during 1917–29, as director of agriculture, he was also responsible for the co-operative credit societies, and became the first principal of its College of Agriculture and a member of its Council of Government. Malaya was his next Colony. While director of agriculture for seven years from 1929, he put new life into the investigation of the food crops and livestock of its peasant farming, formerly overshadowed by its great export crop, rubber. The training of local assistants and general agricultural education also profited greatly from his interest.

By 1940, when Tempany became agricultural adviser in the Colonial Office, Stockdale had put new spirit into the whole Colonial Agricultural Service and made the Colonial Advisory Council for Agriculture, Animal Health and Forestry an influential body, warm in support of his exertions. Soil erosion throughout the Colonial Territories was, at last, being checked; the basic importance of the peasant economy had become recognized; specialist research had begun to be intelligently related to major problems; and study of husbandry and farming systems to be effectively promoted. Further, it was accepted that agricultural development in a territory could not spring from unconcerted pushing of individual commodities but required a policy based on primary physical and ethnic considerations.

In 1940 Tempany, who in his four years as assistant adviser had had a hand in all these developments, became, as adviser, responsible for doing what was possible to carry them on while also wrestling with the acute war-time food-supply problems of all the Colonial territories.

The Colonial Development and Welfare Act, 1940, greatly enlarged the funds for research, and a committee of the Colonial Advisory Council for Agriculture, Animal Health and Forestry was set up to report on research organization in those subjects. In its prolonged, arduous, discussions it fell to Tempany, particularly, to maintain free scope for technical agriculture and science, while conceding a due authority to administrative control. The present Colonial Agricultural Research Committee was set up, conformably with the recommendations, and the idea of a regional basis for research was also adopted. In 1946, a commission of three, under Tempany, visited East Africa for the conference at which initial arrangements for an East African regional organization were drawn up.

At formal meetings, Tempany's conscientious marshalling of facts sometimes tended to irritate his less-patient colleagues who, none the less, respected his tenacity and his high aims for the Service. It was in travel and when dealing with problems out on the land that he was seen at his best. But, indoors or out, he was unfailingly industrious, conscientious, fair-minded and kindly.

Tempany had periods of service on the board of governors of the Imperial Institute, the governing body of the Imperial College of Tropical Agriculture, the Sudan Government London Scientific Advisory Committee on Agricultural Research, the Chemical Council and the Council of the Royal Institute of Chemistry, and in 1950 he received a silver medal of the Royal Society of Arts. Most of his writing went into official papers: he published "Principles of Tropical Agriculture" (1930: with G. E. Mann); "The Practice of Soil Conservation in the British Colonial Empire" (1949); and "Agriculture in the West Indies" (1942). Leisure for writing, for which he longed, and happy opportunity, came in 1946 when, on retiring, he became editor of *World Crops*.

In 1911 he married Annie Frances Agnes, eldest daughter of Robert Goodwin, of Antigua, who died in 1945; their son died, in Nairobi, only two days before the death of his father in London on July 2. His second marriage, in 1946, was to Kate, youngest daughter of William Welfare. F. L. Engledow

### Prof. R. H. A. Plimmer

The distinguished biochemist and one of the founders of the Biochemical Society, Robert Henry Aders Plimmer, emeritus professor of chemistry in the University of London, died on June 18 at the age of seventy-eight.

At the time of his death, Prof. Plimmer was a member of the staff of the Department of Biochemistry at the British Postgraduate Medical School, Hammersmith.

Born on April 25, 1877, the eldest son of Alfred Aders, of Manchester, he adopted the name of his stepfather, Henry George Plimmer, F.R.S., an eminent bacteriologist who undoubtedly influenced him in his choice of a scientific career. He was educated at Dulwich College, University College, and in Geneva and Berlin, and obtained his D.Sc. (London) in 1902 and worked in the Lister Institute for two years as a Grocers' Company research student. In 1904 he returned to University College as an assistant in the Department of Physiological Chemistry, his first teaching post. He was to remain at University College for fifteen fruitful years, during which time he became assistant professor and finally reader in physiological chemistry. He was elected a Fellow of the College in 1906. Together with Bayliss and Starling, he helped to plan and equip the new Physiology School, and he reorganized the teaching of physiological chemistry. His well-known text-book, "Organic and Bio-chemistry", dates from this time, as does the valuable series of "Monographs on Biochemistry", of which he was co-editor with Hopkins, and to which he contributed "The Chemical Constitution of the Proteins". Protein analysis, which he had studied in Emil Fischer's laboratory at Berlin, became one of his main lines of research, and he was long regarded as a leading authority on this subject.

Biochemistry was just beginning to be recognized as a subject in its own right, and the time appeared to be ripe for the formation of a club or society with the object of encouraging closer co-operation among workers in this field. The lead was taken by Plimmer and J. A. Gardner. They called a meeting at University College in January 1911, which led to the founding of the Biochemical Society with Plimmer as its first secretary; Gardner became treasurer in 1913. The present flourishing, vigorous Society owes much to the initiative and foresight of these two co-founders, who steered it through its difficult early days. Plimmer was made an honorary member in 1943 and later wrote the "History of the Biochemical Society" up to the time of the First International Congress of Biochemistry held at Cambridge in 1949.

During the First World War, Plimmer was attached to the R.A.M.C. and worked for a time at the Army Medical College, Millbank. He was commissioned to assay the energy values of the common foodstuffs—a task which entailed many thousands of analyses. The results of this work were later published by H.M. Stationery Office.

In 1919 Plimmer was appointed head of the Biochemistry Department at the Rowett Institute for Research in Animal Nutrition, Aberdeen. His old school friend, John Q. Rowett, had generously contributed towards the founding of this Institute, and had also financed the last Antarctic expedition of Sir Ernest Shackleton, another old Dulwich College boy. But Plimmer was not happy away from London and, when the opportunity came, he applied for the chair in chemistry at St. Thomas's Hospital Medical School, London, the post he was destined to occupy with distinction for twenty-one years—from January 1922 until December 1942.

At St. Thomas's Plimmer found congenial colleagues and facilities for research. He was a successful teacher, beloved by his students, to whom he gave every encouragement while exercising strict discipline. His lectures on inorganic and organic chemistry, bio chemistry, toxicology, and the Nightingale Lecture in elementary science for nurses, were models o lucidity. Full of energy and drive, he carried out a astonishing amount of research on the nutritiv values of foods and their relative vitamin content Plimmer's poultry farm on the roof of his departmen was a source of great interest and, incidentally, man a delicious meal for his colleagues. He was a advocate of the 'balanced diet', and, together wit his wife, wrote several popular books on food value "Food, Health, Vitamins", written by Prof. and Mr Plimmer, ran through nine editions and containe their famous 'square meal' chart.

Plimmer loved hard work at his laboratory bench but he also thoroughly enjoyed his leisure hours a home with his wife and family. Always a kee motorist, he toured extensively on the Continent wit his family during vacation. He enjoyed watchin first-class cricket, loved good music, frequently visite Glyndebourne, and was an ideal host.

On the outbreak of war in 1939, teaching con tinued at St. Thomas's until the Hospital wa severely damaged by bombs in September 194 The staff and students then moved to the Mano House, Godalming, and were permitted to use th laboratories in the nearby Charterhouse Schoo While at Godalming, Plimmer reached the age o sixty-five and retired from St. Thomas's in Decembe 1942. He was too full of energy to remain idle fo long, and he gladly accepted Prof. E. J. King' invitation to work in the Biochemistry Departmen of the British Postgraduate Medical School, Hammer smith. Greatly beloved by all his colleagues, h continued actively working there from January 194 until the end of his life.

The death of his wife in July 1949 was a great blo to him; but he was comforted by the presence of hi eldest daughter and her family, who lived with hi until a few months before his death.

JOHN LOWNDES

## Prof. Gustave Magnel

THE death of Prof. Gustave Magnel on July deprives civil engineering of one of its leading figure Prof. Magnel had a world-wide reputation as th originator of the Magnel–Blaton system of prestres ing concrete, according to which the prestressing wire are formed into a cable of rectangular section b means of spacer grilles, and are anchored by stee wedges hammered into 'sandwich plates'.

Gustave Paul Robert Magnel was born at Essche in the province of Antwerp in 1889, and graduate in civil engineering in the University of Ghent i 1912. His early working years were spent in Englan where, during the First World War, he worked a assistant, and later chief engineer, for the firm o D. G. Somerville and Co., of London.

After the War he returned to Ghent, and to hi old University, where he became professor of struc tures and reinforced concrete, and director of th concrete laboratory. Between the Wars he becam one of the earliest enthusiasts for prestressed con crete; it was during the Second World War that h developed his own system of prestressing. The syste did much to widen the scope of the new and revolu tionary technique of prestressing, and has been use in many different countries for bridges, buildings an circular structures such as tanks and silos. Pro Magnel himself designed most of the early structure restressed by his system—as a consulting engineer e had an international reputation.

As a university professor, Magnel was acknow-dged to be outstanding. His lectures were remark-ble for their clarity of exposition, and the same uality marked his writings. His numerous technical ooks are standard text-books; they cover a wide ange of subjects, and contain an unusual wealth of ractical detail. Chief among his published works are: Pratique du Calcul du Béton Armé" in four volumes, f which Volume 4 is "Le Béton Précontraint", Cours de Stabilité des Constructions" in four olumes—the complete University course in struc-ures—and "Le Calcul pratique des Poutres Vieren-el". "Le Béton Précontraint" has been translated to English, and published in Great Britain. He as also the author of numerous papers in French nd English (in a paper given before the Institution Civil Engineers in 1949 he introduced the Magnel-laton system of prestressing to Britain), and he itiated the publication of the bilingual periodical *récontrainte–Prestressing.*

As a lecturer, Prof. Magnel was well known in the nited States and in South Africa, as well as in Britain, his perfect command of English no less than his command of his subject always ensuring him an appreciative audience. Wherever he went he was an outspoken crusader for high-quality concrete and was forthright in his condemnation of slipshod workmanship.

Prof. Magnel had been honoured both in Great Britain and in the United States as well as in Belgium. A member of the Belgian Royal Academy, he was elected a member of the Institution of Structural Engineers in 1934, and of the Institution of Civil Engineers in 1950. He was also a member of the American Society of Civil Engineers and the American Concrete Institute, and a holder of the American Frank P. Brown Medal. He was chairman of the Belgian Prestressed Concrete Group, and senior vice-president of the International Federation of Prestressing. In this capacity his keen intellect, sound judgment and always unruffled courtesy, as well as his genius for smooth organization, will be sadly missed at the forthcoming International Congress at Amsterdam. His dynamic, yet always kindly, personality will be missed by all who knew him.

BETTY CAMPBELL

# NEWS and VIEWS

## hemistry at the Imperial College, London :

### Prof. E. A. R. Braude

In taking up the appointment of professor of ganic chemistry at the Imperial College of Science d Technology, London, Dr. E. A. R. Braude llows a distinguished line starting with Hofmann d continuing to recent times through Frankland, mstrong, Tilden, Thorpe and Heilbron. South ensington has been celebrated not only as a centre research in the subject but also as a training ound for students, from the time of Perkins, father d son, onwards. In the appointment of Dr. Braude e College has selected one of the leading young itish organic chemists, who has a wide and im-rtant range of interests; at the same time, it has cured the services of one deeply experienced in the ecial educational methods associated with this hool. Dr. Braude was born in 1922. After a dis-nguished undergraduate career at the Imperial llege, he continued there as a postgraduate research udent under Sir Ian Heilbron. He was awarded e Ph.D. degree in 1945. He was appointed assistant cturer in 1946, lecturer in 1947, and reader in ganic chemistry in 1952. He was awarded the eldola Medal of the Royal Institute of Chemistry r 1950, and received the D.Sc. degree in the same ar. He is a member of the Council of the Chemical ciety.

### Prof. G. Wilkinson

The chair of inorganic chemistry in the University London tenable at the Imperial College of Science d Technology, from which Prof. H. V. A. Briscoe tired last year, has been filled by the appointment Dr. G. Wilkinson, who graduated there as a Royal holar in 1941 and was elected Frank Hatton prize-an. Dr. Wilkinson then undertook research in organic chemistry at the College until, in 1943, was appointed to a research post in the joint itish–Canadian–United States atomic energy pro-t, serving for three years at Montreal and at Chalk ver. After the War, he was a research associate, engaged in Prof. G. T. Seaborg's laboratory in the University of California, on investigations of radioisotopes leading to quantitative studies of the reaction of high-energy protons with the heavier elements; he later held a similar post in Prof. C. D. Coryell's laboratory at the Massachusetts Institute of Technology, working on the conditions of formation of complexes by phosphorus halides. Since 1951, as assistant professor of chemistry at Harvard University, he has been directing a research group studying, *inter alia*, the properties of bis-*cyclo*pentadienyl compounds of the transitional elements, and in association with Prof. R. B. Woodward and others has been responsible for considerable progress in this new field of chemistry. Last year Prof. Wilkinson, as John Simon Guggenheim Fellow, spent some months in Prof. J. Bjerrum's laboratory at Copenhagen. By his delight in experimental investigation, his experience as a lecturer on inorganic and nuclear chemistry, and his administrative services as secretary to the Department of Chemistry at Harvard, he will take to the Imperial College enthusiasm for the development of studies in modern aspects of inorganic chemistry and wide knowledge of the facilities now available for that purpose.

## Physics at King's College, London :

### Prof. W. C. Price

His many friends on both sides of the Atlantic will be pleased to know that the title of professor of physics in the University of London has been conferred on Dr. W. C. Price in respect of his appointment at King's College. Dr. Price has held the post of reader in experimental physics in the College for several years, and is well known as a spectroscopist who has worked mainly on the structure of polyatomic molecules, both in the vacuum ultra-violet and in the infra-red spectral regions. He was the first to show that the short-wave spectra of a large number of basic molecules, such as acetylene, ethylene, benzene, water, the alkyl halides, etc., can be interpreted as a succession of electronic transitions which converge to limits corresponding to the photo-ionization of particular electrons within the molecule. This phase of Dr. Price's work was started while he was a Commonwealth Fellow at the Johns Hopkins University during 1932–35 and developed later at Cambridge, where he was on the staff of the Physical Chemistry Department and held a fellowship of Trinity College.

During the later years of the Second World War, Dr. Price became attached to Imperial Chemical Industries, Ltd. (Billingham Division), where he applied infra-red techniques to industrial problems, particularly those concerned with the war effort. During 1946–47 he was research associate at the Molecular Spectroscopy Laboratory in the University of Chicago, and in 1949 he took up his appointment at King's College, London. His contributions in infra-red spectroscopy include the experimental evidence for the bridge structure of diborane and its metal derivatives, the elucidation of the nature of the vibrations of the peptide link, the theory of infra-red reflexion spectra from molecular crystals, and high-resolution studies of emission spectra of molecules and radicals. Dr. Price has during the past few years contributed greatly to the teaching duties and administration of the Physics Department at King's College.

## Ford Prize for Peaceful Uses of Atomic Energy

ON the opening day of the Geneva Conference on the Peaceful Uses of Atomic Energy, it was announced by the Ford Motor Co. that it will put aside one million dollars to provide an annual prize for the best contribution to the subject. The award is to be made by an international jury, and the honorarium of 75,000 dollars and a medal may go to an individual or a group of scientists, irrespective of race or political views. If no award is made, the money is to be used for providing fellowships for scientists likely to contribute to the advancement of the peaceful application of atomic energy. This munificent gesture is a response, the Company states, to President Eisenhower's appeal to industry to offer an incentive in finding new ways of using atomic energy for the benefit of the human race, and has been made by Mr. Henry Ford and his brothers as a memorial to their father.

## New Reactor at Harwell

A FULL-SCALE, very low-power model of the Dounreay fast reactor has been built at Harwell and should be in operation before the end of this year. It has been named ZEUS (Zero Energy Uranium System) and will provide data relating to the design and operation of the Dounreay experimental plant. ZEUS is a fast reactor like ZEPHYR (the Zero Energy Fast Reactor), and the reacting core contains only the fuel, its canning material, and the coolant; there is no moderating material such as heavy water or graphite to slow down the neutrons. The fuel is uranium highly enriched in uranium-235 (from the diffusion plant at Capenhurst), instead of the plutonium fuel used in ZEPHYR. The fuel is in the form of long tubes which are mounted vertically to form a hexagonal-shaped core. The core is surrounded by an envelope of natural uranium, the purpose of which is to absorb the neutrons from the core and so produce plutonium. The Dounreay reactor and ZEUS are both breeder reactors in the sense that the amount of plutonium produced in the
reactor should exceed the amount of uranium-2
burned in the core. It is not expected that t
breeding margin will be as high as it was in ZEPHY
where the amount of fresh plutonium produced in t
reactor was found to be about double the amou
consumed in the core. The operating power-level
ZEUS will be only about one-millionth of that of t
proposed Dounreay reactor. This will be sufficie
for experimental studies. Because of the compl
technical problems which they pose, fast reactors w
not play a prominent part in the early stages of t
utilization of atomic energy; but when they do com
into widespread use they will make it possible for
substantial supply of fissile material to be obtain
economically from a relatively modest supply
uranium.

## Radio-astronomy at Cambridge

THE University of Cambridge has accepted t
offer of a gift by Mullards, Ltd., of ten annual su
scriptions of £10,000 each, for continuing a
extending the work in radio-astronomy which is no
being carried out at the Cavendish Laboratory.
is intended to set up a new observatory on a s
near Cambridge, which will be known as the Mulla
Radio-astronomy Observatory. The grant will ma
it possible both to obtain the use of the land
provide laboratory buildings, and to construct ne
instruments. It is hoped in this way to develop
number of the lines of research which now appear
offer great promise. During the past two years
survey of radio stars has been completed at Ca
bridge which led to the location of nearly tw
thousand radio sources. Only a small fraction
these could be related to optically observable objec
and an analysis of their apparent distribution
space has suggested that most of them represent a
extremely rare and intense class of source; on th
interpretation most of the sources observed lie beyo
the reach of the most powerful optical telescope
in regions where the predictions of different cosm
logical theories diverge. The extension of the
observations, their comparison with cosmologic
theories, as well as work on the general emissi
from the galaxy and on the structure of the out
layers of the solar atmosphere, represent some of t
investigations which it is hoped to undertake at t
new Observatory.

## International Co-operation on Purification Brackish Water

GREAT BRITAIN has joined an international schem
for research on de-salting saline waters by electr
dialysis; the work will be carried out in The Nethe
lands. In many countries, difficulty is being found
providing the increasing quantities of fresh water r
quired for domestic and industrial use. For examp
sea-water is infiltrating into freshwater wells in t
Thames estuary and it is becoming more and mo
difficult to suggest other sources that do not invol
expensive, long-distance pumping. Talks on t
possibilities of various methods of de-salting wat
have been going on for some time under the auspic
of O.E.E.C. One promising process is electrodialys
—the removal of salts from a liquid flowing betwe
pairs of ion-selective membranes, by means of
electric field. Research on this method is already w
advanced in The Netherlands. The Dutch recent
offered to carry out development work in co-operati
with other countries showing an interest. Gre
Britain has joined The Netherlands, South Afric

Australia and Algeria (representing France) in paying for this work; the problems to be solved are mainly those of bringing up the process from small to large pilot-plant scale. In Britain, an Admiralty team has been working on scale- and foam-prevention in the distillation of sea-water. The Department of Scientific and Industrial Research has now given 5,000 for an extension of that programme to cover other waters. A Dutch scientist is joining the team. Two other processes have been put forward by the French, namely, certain aspects of ion-exchange and of solar distillation, which may be suitable for use in very hot, dry areas; no co-operative group for their study has yet been formed.

### New Discovery at Swanscombe, Kent

Some time must necessarily elapse before a complete study can be made of the portion of a human skull bone discovered at Swanscombe by Mr. and Mrs. B. O. Wymer, Mr. J. Wymer, and Mr. Adrian Jones on August 1. It can, however, be confirmed that the bone is a right parietal, and it fits perfectly with the left parietal and occipital which were discovered on the same site by Mr. A. T. Marston in January 1935. This in itself is very satisfactory, and will enable further evidence to be obtained from the bones as a whole. Meanwhile, the remarkable fact that another portion of the same skull has been found after an interval of twenty years is a striking justification of the policy of the Nature Conservancy in preserving sites of scientific importance. The remaining region of the Swanscombe skull has still to be discovered, and it is very much to be hoped that it will be found during the further excavations which it is understood are to be made. It is therefore of the greatest importance that the site should be protected from damage.

### Commonwealth Agricultural Bureaux

The growth of the Commonwealth Agricultural Bureaux, like so many other British organizations, has been one of adaptation and adjustment, often on an empirical basis, to the needs and mood of the time. It dates back to 1909, when recommendations were made for forming an Entomological Research Committee, duly leading in 1913 to the foundation of the Imperial Bureau of Entomology, and to 1920, when an Imperial Bureau of Mycology was started. In addition to these two bodies, now named the Commonwealth Institute of Entomology and the Commonwealth Mycological Institute, respectively, eleven other Commonwealth centres were later founded, as follows: Institute of Biological Control, Bureau of Agricultural Parasitology, Bureau of Animal Breeding and Genetics, Bureau of Animal Health, Bureau of Animal Nutrition, Bureau of Dairy Science, Bureau of Forestry, Bureau of Horticulture and Plantation Crops, Bureau of Pastures and Field Crops, Bureau of Plant Breeding and Genetics, and Bureau of Soil Science. Though these centres are situated in Great Britain, they are essentially Commonwealth organizations and are in the hands of an Executive Council which comprises one member from Great Britain and one from each of the Dominions of the British Commonwealth (including the Republic of India and the Federation of Rhodesia and Nyasaland) and one member representing the Colonial Territories. One of the recommendations of the Commonwealth Agricultural Bureaux Conference of 1946 was that the Executive Council should issue a conspectus showing the subjects or aspects of subjects covered by the journals of the institutes and bureaux. At the same time it was decided to incorporate a brief account of the history and origin of the Commonwealth Agricultural Bureaux organization. As a result, the conspectus was issued in 1949 giving a short description of the history, work, administration and finance of the Bureaux and a detailed review of the subjects covered by each institute and bureau. The conspectus has now been revised and is a valuable pamphlet of nearly fifty pages (London: H.M.S.O., 1955) showing the state of the Commonwealth Agricultural Bureaux at the time of going to press in October last year.

### National Institute of Agricultural Botany

In his address to the Fellows of the National Institute of Agricultural Botany, Cambridge, at the annual general meeting of the Institute on July 14, Sir William Slater said that a fundamental feature of the Institute's work has been the introduction of greater precision into the evaluation of the different varieties of agricultural and horticultural crops, and as a result the farmer and grower now have information upon which they can rely. With regard to plant breeding, he believes that undue emphasis is sometimes laid on a search for an ideal variety incorporating all possible good qualities, whereas a sound range of good varieties of known performance, from which the farmer can select according to his requirements, may be preferable. Prof. T. J. Jenkin, chairman of the Council, in presenting the annual report for 1954, referred to the arrangements for transfer from the Welsh Plant Breeding Station of the certification of the Aberystwyth strains of grasses and clovers, and for sowing an additional acreage of foundation seed as the first stage towards full responsibility by the National Institute of Agricultural Botany for the production of stock seed of these strains. A recommended list for the potato crop has been produced for the first time, the certification schemes for cereals have been developed and a new scheme inaugurated for vegetables. Considerable progress has also been made in the national certification scheme for herbage plants. In conclusion, he was able to announce the authorization by the Ministry and Treasury of a capital grant for a much-needed extension to the headquarters building and for improvements in glasshouse accommodation.

### Institute of Science Technology

In 1948, the Science Technologists Association was formed for technicians in science laboratories in educational institutions and in industry who were not covered by the Institute of Medical Laboratory Technology. The membership has now grown to approximately 1,300, and many branches have been formed providing for local activities. The Education Board of the Association has arranged examinations at both certificate and diploma level, and the Association has assisted in the training of technicians in other ways and has maintained a technical information service. A primary purpose of the Association had always been the formation of an Institute of Science Technology, and this was accomplished at an extraordinary general meeting of the Association held on May 21. The Institute has been granted a certificate of incorporation and has taken over the affairs of the Association. Membership of the Institute will consist of Fellows, honorary Fellows, associates, ordinary members and registered students; the training scheme approved by the Institute is a five-year course of study (three years for a certificate followed by two further years for a diploma) leading to the associate grade. Information on the aims of the Institute, examination syllabuses and details of membership may be obtained from the registered office of the Institute: Hon. General Secretary, F. W. L. Croker, Chemistry Department, Imperial College of Science and Technology, London, S.W.7.

## Engineering Appointments in Great Britain during 1954

During 1954 the Professional Engineers Appointments Bureau (9 Victoria Street, London, S.W.1) submitted particulars of more than nine thousand engineers for vacancies notified in civil, mechanical and electrical engineering, and this is the highest annual number recorded since the Bureau was set up nine years ago by the Institutions of Civil, of Mechanical and of Electrical Engineers. There has been an increase in the number of registrations with the Bureau, many from overseas, and this increase contributes to the better service which the Bureau can offer to employers. On the other hand, because of the full employment position, there is a reluctance on the part of many engineers to change their employment unless substantial benefits are likely to result. The main demands in civil engineering have been for engineers with wide design experience, good contractors' experience and for young engineers prepared to accept overseas posts; there has also been a big increase in technical vacancies notified by local authorities. In mechanical engineering requirements have been varied and have included posts for engineers with experience in chemical engineering plant, hydraulics, servo-mechanisms, production and management. The major proportion of electrical vacancies have called for experience in the sphere of electronics and light-current engineering, including instruments.

## Forestry in Northern Ireland

In an introduction to a well-illustrated pamphlet issued by the Minister of Agriculture in Northern Ireland, entitled "Forestry in Northern Ireland" (pp. 20; Belfast, 1954), a brief historical review is given of the forests of the region in the past. It was not until 1903 that a definite step to stop deforestation, which the great storm of that year had increased, was taken. A forestry branch of the Department of Agriculture was inaugurated, technical instruction was undertaken and Avondale in Co. Wicklow was acquired as the first forestry centre and training school. Progress has been made since then. The forest policy laid down is governed by three principal factors. First, there is the compelling need, which two World Wars have demonstrated, to reverse the centuries-old process of deforestation and to create home-grown timber resources equal to emergency requirements. Secondly, it is necessary to provide productive work in areas of serious unemployment; and thirdly, though private planting can contribute usefully, under present economic conditions any such contribution must be small. A Forestry Act (Northern Ireland) was passed in 1953, and afforestation and other work is proceeding under the Act. As in so much of Britain, sitka spruce is the most important single species in the reafforestation programme.

## The German Plastics Industry

The German Forschungsgesellschaft Kunststoffe e.V., a union of 189 firms, was founded in 1953 with the object of promoting the scientific investigatic and practical application of plastics (*Kunststoffe*) ar the development of the industry. It has founded tl Deutsche Kunststoff-Institut in Darmstadt, und the direction of Prof. K. H. Hellwege and in tl grounds of the Technical Institute, and the ne Institute is expected to be functioning fully at tl end of 1956. It will comprise laboratories and worl shops, a library and documentary department, and separate hall of manufacture equipped with all tl necessary machinery. The staff will comprise eigh to ten physicists, chemists and engineers. The co will be largely met by members of the Forschung gesellschaft, with assistance from the State of Hess The programme of research will be under the directio of a board, including the chairman of the Forschung gesellschaft, State and town officials, the Rector the Technical Institute of Darmstadt, and repr sentatives of science and industry. The foundatio stone was laid last May, with appropriate ceremonie in which the Minister of Education participated. casket containing specimens of various plastics wa enclosed in the foundation stone. The organizatio has recently established a literary service called *Literatur-Schnelldienst*, which is available to membe and non-members. This is planned to appear monthl and takes the form of a prompt documentation b titles and short abstracts of all publications an patents, both German and foreign, of interest in a branches of the science and technology of plastic This publication, a specimen of which in the form o photostat copies of sheets has been received at th office of *Nature*, is apparently issued by the Arbeits gemeinschaft Deutsche Kunstoff-Industrie, 4 Güter platz, Frankfurt-am-Main 1, the director being D H. Saechtling. The price of the *Literatur-Schnelldiens* is given as 80 DM. to members of the Forschungs gesellschaft and 200 DM. to non-members per annum

## Announcements

The Wellcome Trustees announce that, with th approval of the chairman of the Medical Researc Council, they have appointed Brigadier J. S. K Boyd to be a Trustee as from January 1, 1956, i succession to Prof. T. R. Elliott, who is retiring fron the trusteeship in October. Brigadier Boyd i relinquishing the directorship of the Wellcom Laboratories of Tropical Medicine on December 31 and will be succeeded by Dr. R. S. F. Hennessey who, until his recent retirement, was director o medical services, Uganda.

The following lecturers in the University o Aberdeen have been appointed readers in the subject stated, as from October 1: Dr. H. W. Kosterlit (physiology); Dr. T. N. Morgan (materia medica) Dr. W. P. D. Wightman (history and philosophy o science); Dr. W. T. H. Williamson (soil science).

The French Society of Metallurgy is holding it annual "Journées Métallurgiques d'Automne" i Paris during October 24–29. Further informatio can be obtained from the Société Française d Métallurgie, 25 rue de Clichy, Paris 9$^{e}$.

The Scottish Group of the Nutrition Society i holding a symposium in Aberdeen on September 1 on "Cholesterol and Fat Metabolism in Relation t Diet and Disease". Both the biochemical and clinic aspects of the subject will be considered. Furthe particulars can be obtained from Dr. A. M. Thomson Department of Midwifery, University Medical School Foresterhill, Aberdeen.

# CONFERENCE ON THE EFFECTS OF NUCLEAR WEAPONS

A WORLD conference of scientists to consider the effects of nuclear weapons was organized by the World Association of Parliamentarians for World Government and held at the County Hall, London, during August 3–5. The Right Hon. Clement Davies, president of the Association, opened the conference, and the Right Hon. Walter Elliot took the chair during the subsequent sessions.

Earl Russell opened the debate and moved his resolution urging Governments to acknowledge publicly that their purposes cannot be furthered by world war. He asked scientists to collect together the results of their investigations of the effects of nuclear warfare, and then see that they are clearly expressed in simple language and disseminated as widely as possible. Not only nuclear physicists, but also geneticists, meteorologists, authorities on soil and crops, and other experts will be needed in the investigations. Some of the work has been done already, but what is needed is a series of reports by internationally acknowledged authorities on the subjects concerned.

These reports would make it clear that a nuclear war would not bring victory to either side, but would probably create a planet destitute of life, except for a few mosses and fungi. If nuclear weapons are intended only as deterrents, and there is no intention of using them, then it would seem simpler and more economical to have the deadlock admitted and the impossibility of war acknowledged. War can no longer serve as an instrument of policy. We cannot wait to learn this by experience, because the experience would probably be that of universal death.

It is only the first steps that depend upon men of science as such. Their pronouncements will have to be taken up and clarified and emphasized by leaders of public opinion, who will have to make their weight felt by statesmen of East and West alike.

Another important sphere lying within the scope of science is the possible peaceful uses of atomic energy and of other scientific discoveries. The tendency of the general public to think of scientists as merchants of death must be combated, and it must be made clear that science could and would bring benefits to mankind as great as the disasters it has been rendering possible. If the world were liberated from fear of war, science could abolish poverty and raise the standard of living throughout the world, make deserts fertile, and ameliorate inclement climates.

Collective hatreds have darkened history since the dawn of organized society. They are about to cease, either because no one will be left alive to feel them, or because men will have learnt the elementary wisdom that only by overcoming collective hatred can the human race survive.

Earl Russell was followed in the debate by a number of distinguished speakers, including Prof. J. de Castro, Prof. M. L. Oliphant, Prof. E. Rabinowitch, Prof. A. J. Ayer, Prof. A. Topchiev, Lord Boyd Orr, Lord Beveridge, Prof. C. H. Waddington, Prof. R. W. Ditchburn and Prof. G. Boschi. They generally welcomed his proposals, in some cases with reservations, and stressed the dangers of nuclear weapons and the importance of developing the peaceful uses of nuclear energy.

On the second day, the scientists divided into three commissions to study the destructive potential of nuclear weapons and the hazards of the large-scale peaceful use of nuclear energy, the international control of atomic energy, and the individual and collective responsibility of the scientist. The other delegates debated the responsibility of Parliaments in the nuclear age.

The main task of the three commissions was to define more precisely their terms of reference and, where possible, to pose the questions that need to be answered. It is proposed that their reports be circulated to interested scientists all over the world with a request for comments, suggestions and details of scientific and technical investigations bearing upon them. These will be incorporated in a final report to be presented at another conference to be held in The Hague about a year hence.

The first commission examined the destructive potentials of nuclear weapons, the possible consequences of their massive use in war and in tests, and the possible harmful effects of the peaceful uses of atomic energy. It was agreed that its investigations should be carried out under the following headings: (*a*) physical destruction; (*b*) effects on individuals; (*c*) effects on animals and crops; (*d*) long-term genetical effects on human beings, animals and plants; (*e*) meteorological effects; (*f*) effects of a rise in the general level of radioactivity in the atmosphere and the soil. Prof. J. Rotblat, of the Physics Department, Medical College of St. Bartholomew's Hospital, Charterhouse Square, London, E.C.1, was appointed secretary of the commission.

The second commission examined the technical problems of the supervision and control of the production and use of nuclear weapons with the view of enforcing their prohibition. A number of questions for further study were posed and classified under five headings: (*a*) Detection of existing weapons and fissile materials: Can direct physical methods or other indirect methods be used for the detection of existing nuclear weapons and fissile materials, and if so, what are they? (*b*) Inspection of means of delivery of nuclear weapons: Can surprise attacks be made impossible by setting up a system of control of the means of delivery of such attacks, or of dangerous concentrations of air, naval or land forces for such an attack; for example, by establishing points of control in ports, road junctions, airfields, etc.? (*c*) Control of mines and plants producing or employing fissile materials: Are the possibilities of the control of diversion from these plants of fissile materials affected by new scientific or technical developments, and are there methods by which the conversion for military uses of materials used in power plants can be made difficult or preventable? (*d*) Adaptation of controls to possible future developments: Can the control methods be made flexible enough to be adaptable to possible new developments such as new methods of initiation of thermo-nuclear reactions? (*e*) Nuclear weapon tests: How could nuclear tests be detected and how effective could be the cessation of such tests?

The commission said that the study of these questions would be greatly facilitated by closer international co-operation of scientists, and by the reduction of secrecy to a minimum. Dr. P. E. Hodgson, of the Physics Department, University College, London, W.C.1, was appointed secretary of the commission.

The third commission examined the responsibility of scientists for the direction of their work, the uses to which it is put, and public knowledge of its implications. Dr. J. Bronowski, of the National Coal Board, Central Research Establishment, Stoke Orchard, Cheltenham, Glos, was appointed secretary of the commission.

The representative character of the conference was increased by the presence of a delegation from the U.S.S.R. comprising Academician A. Topchiev, professor of organic chemistry and general secretary of the Academy of Sciences of the U.S.S.R., Prof. O. A. Golounsky, director of the Institute of Criminology, University of Moscow, Prof. A. V. Kusin, a biochemist, and Prof. M. A. Markov, a theoretical physicist. The atmosphere of the discussions was cordial, and their conclusions unanimous.

The final day of the conference was devoted to the presentation and discussion of the reports of the three commissions. At its close, Earl Russell moved his resolution, which had been slightly modified as a result of the previous day's discussions: "Since in any future world war nuclear weapons will probably be employed and since such weapons threaten to bring immeasurable suffering for humanity, and material destruction, and possibly even the end of mankind, we urge, therefore, the governments of the world to realize and to acknowledge publicly, that their purposes cannot be furthered by world war; consequently we urge the full and open examination of the implications of recent scientific developments for humanity as a whole and the promotion of peaceful means for the settlement of all matters of international dispute". The resolution was carried unanimously.

P. E. HODGSON

# LONG ASHTON RESEARCH STATION

## FIELD-DAY

FIELD-DAY was held at Long Ashton on July 20 in conjunction with the fifty-second annual general meeting of the governors, members and associates of the National Fruit and Cider Institute. Captain D. M. Wills, chairman of the governors, presided.

In reviewing the work of the Station during 1954, the director, Prof. T. Wallace, referred to the promising results obtained from foliage sprays and soil dressings of chelated compounds of iron in the control of lime-induced chlorosis of fruit trees. Although these compounds, derived from ethylenediamine tetra-acetic acid and related substances, are as yet expensive, he believes that the residual effects obtained from a single application to calcareous soils make it likely that they can be developed to replace the present tedious technique of injecting pellets of ferrous sulphate into the trunks of affected trees. The chelates have been found to be photosensitive, and it is therefore necessary to water them well into the soil to prevent their breakdown at the soil surface.

In a brief account of the work of the Agricultural Research Council Unit of Plant Nutrition, Prof. Wallace recalled Dr. Nicholas's participation in experiments at the McCollum Pratt Institute which had shown molybdenum to be an essential constituent of the flavoprotein enzyme, nitrate reductase; he outlined investigations that are being made on other metallo-flavoproteins and on the valency changes of molybdenum within plants.

In a tour of the plantations, members saw three-year-old trees of Cox's Orange Pippin and Bowden's Seedling that had been newly grassed-down in further studies of the effect of cover crops on the availability of soil nutrients and of their interaction with fertilizer treatments. Experiments made with cider-apples between 1946 and 1952 had shown that, compared with clean cultivation or annual cover-crops, a grass cover rapidly increased the potassium and phosphate status of the leaves while decreasing the nitrogen status; the effects on tree growth and fruit yield had not been readily determinable as the trees had been well established when the covers were sown.

Current trials with growth-substances were demonstrated. In the search for a compound suitable as a thinning-agent for heavy-bearing varieties of apple naphthylacetamide has been tried for the first time in place of α-naphthalene acetic acid (NAA), which had caused a loss of marketable crop in a number of consecutive years. Sprays of the amide applied four days after petal-fall gave variable results: they had drastically over-thinned test branches of Crawley Beauty when used at half the strength (50 p.p.m.) recommended in the United States, whereas they had failed to effect any thinning of Laxton's Superb even when used at 1½ times the recommended strength.

From the bareness of their branches it was possible to distinguish trees of Worcester Pearmain that had received sprays of 30–50 p.p.m. 2:4:5-TP (2:4:5-trichlorophenoxy propionic acid) in August 1953. Treatment had permitted apples of good quality to be harvested fourteen days in advance of the normal crop, and had seemed likely to prove valuable to growers anxious to catch the early market. Damage to the treated trees had, however, become apparent early in 1954, when their yield was only 25 per cent of that from untreated controls. The uncertainty attending empirical trials of growth-substances has served to emphasize the importance of the investigations that Long Ashton has been making since 1946 into the production of natural auxins during the development of apples and other fruits.

Members were also shown experiments to decide the best method of rooting gooseberry cuttings, and demonstrations were made of the frame-working and top-grafting of apples and of the spraying of dwarf pyramid apples by an automatic machine developed at the Research Station.

Laboratory exhibits illustrated the techniques used in determining the performance of spray machinery and materials: these included measurements of droplet size, of the distribution and persistence of various formulations of copper compounds on potato leaves, and of the residues of DDT and captan on apples and other fruits. A new method for the determination of small amounts of captan has shown a maximum deposit of 19 p.p.m. on fresh strawberries successfully sprayed in 1954 against *Botrytis*, using three applications at 0·25 per cent. While no taint had been apparent in the fresh fruit, a slight taint had developed during the storage of canned fruit.

Other exhibits showed the use of radioactive tracers to follow the passage of systemic insecticides through bean and apple plants; and the production of cankers on apple trees by inoculation with mycelium or spore suspensions of *Gloeosporium perennans* and the formulation of a BHC – DDT emulsion as a substitute for winter washes for apple trees. The need or supplementing this emulsion with a later spray against the red spider mite (*Metatetranychus ulmi* Koch) was stressed, and favourable reports were made of the acaricide chlorbenside (*p*-chlorphenyl -chlorbenzyl sulphide), which has given nearly complete kill of the winter eggs of the mite when pplied at 0·05 per cent just before hatching of the ggs.

In an array of casks and bottles appropriate to the occasion, the Cider and Fruit-juices Section included attractive samples of concentrates and syrups prepared from black currants, strawberries and raspberries. Paper chromatograms showed the amino-acids distinctive of apple and pear juices and the changes in organic acids taking place during fermentation. Besides the bacterial breakdown of malic acid to lactic and succinic acids, the reduction of quinic acid to dihydroshikimic acid has recently been observed, a finding of some interest because of the role postulated for quinic acid in aromatic biosynthesis. Chromatograms of leaves of apple and pear and of the apple–pear hybrids produced by Mr. M. B. Crane at the John Innes Institution demonstrated that the hybrids had inherited the phenolic (tannin) components of both parents.

The cider-house contained a collection of gooseberries showing the characters that are being used in their classification, which is at present very confused; there was also a selection from the many varieties of perry pear collected during the past two years in a survey of West Midlands orchards, arising out of revived interest in perry. The longevity of perry pears ("He who planteth perry pears planteth truly for his heirs") was illustrated by a recent photograph of a vigorous tree planted at Holme Lacy, Herefordshire, in 1790, and reputed at one time to have occupied ¾ acre and to have yielded five to seven tons of fruit in one year.

---

# ENDOCRINOLOGY AND AGEING

A MEETING of the British Society for Research on Ageing was held at the Ciba Foundation, 1 Portland Place, London, on June 9.

The opening paper was read by Dr. V. Korenchevsky on "Endocrinological Aspects of Gerontology". He pointed out that in studying the relationships of the endocrine glands to ageing processes the following three points have to be taken into account: (1) the changes in each gland with age; (2) the effects of their hypo- or hyper-secretion, as the case might be, in old age; (3) the use of hormones in treating the ailments of old age.

In the case of the testis, Dr. Korenchevsky listed seven changes which are characteristic of both ageing and castration and twelve which differ in these two conditions. Among the former are atrophy of liver, kidneys, heart and skeletal muscles, an increase in fat deposition and fatiguability and a pale, lifeless, non-elastic skin. On the other hand, the adrenals and the pituitary are atrophied in old age, but hypertrophy as a result of castration. Dr. Korenchevsky pointed out that castration can accentuate old-age changes, quoting the results of his own experiments on senescent rats, and those of previous workers, who have shown that castrated men of forty look like old men of sixty.

The thyroid gland in old age shows degenerative and sclerotic changes; but in some cases an apparently normal or even hyperactive gland has been found. However, the fact that most thyroids show degenerative changes in old age has for some time led to thyroid deficiency being thought of as a primary cause of ageing. Experimental evidence shows that thyroid deficiency is not itself the primary cause of ageing; but it can intensify and accelerate those degenerative processes which are present both in ageing and thyroid deficiencies. There is a possibility, on the other hand, that excessive thyroid secretion might accelerate ageing by wearing out the organism.

Ageing and hypofunction of the adrenal have some six effects in common, namely, increased fatiguability, asthenia, tendency to skin pigmentation, low basal metabolism, accumulation of toxic metabolites, mental depression and apathy. On the other hand, adrenal hypofunction produces hypotension and old age tends to produce hypertension.

The conclusions presented by Dr. Korenchevsky were that while degenerative changes in the three endocrine organs considered can produce, and therefore intensify, many of the conditions present in old age, they are not the basic causes of ageing. Experiments on senescent rats by Dr. Korenchevsky and recent clinical observations show that the hormonal treatment might be useful only in those cases of old age in which there is a deficiency of the respective endocrine. The treatment removes this deficiency and the intensifying effect which it exerts on the processes of ageing.

Following Dr. Korenchevsky's general survey, three papers were read—two on the ageing ovary and one on hormonal changes in the menopause. These included a thoughtful discussion of the ovary by Prof. P. L. Krohn, an interesting paper on hormonal relationships in the menopause by J. A. Loraine and a detailed account of a critical series of researches carried out in Amsterdam by Dr. O. Mühlbock and Drs. L. Boot and P. J. Thung. The latter paper was read by Dr. P. J. Thung.

Prof. Krohn pointed out that in considering the ageing processes it must be remembered that the ovary is a composite organ with several jobs to do; for example, it has not only to produce ova but also a series of reproductive hormones. The ageing of these two functions may not always run in parallel. Also a specially produced tissue, such as the corpus luteum, has a life and an ageing time-table of its own, not necessarily related to the other ovarian changes. Furthermore, the fœtal ovary (for example, in the mare) may be twice the size of the mother's ovary, due to great overgrowth of the interstitial elements, and the subsequent degeneration of these cells might be described as a form of ageing. While all these factors must be taken into account in studying the ageing ovary, the reactivity of the endometrium to hormonal stimulation must also be considered. The uterine endometrium in women, for example, remains after the menopause responsive to the injected hormones for a considerable period of time. Presumably, therefore, the menopause is due to ovarian hormonal changes rather than to change of reactivity of the uterus. Presumably this again is a case of ovarian functions ageing at different rates, for women have been known to become pregnant after several years of amenorrhœa, which suggests that the ovulatory processes have not aged as rapidly as the hormonal. That a completely menopausal ovary is still fulfilling some sort of function is indicated by the fact that a second series of menopausal symptoms can follow the removal of post-menopausal ovaries.

The reproductive life in animals seems to continue, although becoming reduced, as the animal becomes older, and a post-menopausal period in women is a biological luxury of very recent origin.

Apart from the ageing of the ovary, the ageing of the individual ova must be considered. Two schools of thought exist here. The first believes that the ovary receives its quota of ova early in its life, and the other that new ova are constantly being destroyed and formed. This controversy has not yet been settled, although Prof. Krohn expressed some bias towards the former view.

Dr. Loraine directed attention to the fact that gonadotrophin titre in both the urine and the serum of menopausal and post-menopausal women is relatively high. It was shown by Heller and Shipley in 1951 that women who are less than twenty-five years beyond the menopause have a gonadotrophin excretion significantly higher than those in whom menopausal symptoms occur more than twenty-five years before the investigation. Menopausal gonadotrophin resembles in its biological properties the gonadotrophins excreted by men and by non-pregnant women. It has been generally assumed that menopausal urine contains entirely, or predominantly, follicle-stimulating hormone. Recent work in Edinburgh has, however, shown that this material is in addition a relatively rich source of a hormone stimulating interstitial cell activity.

Bioassay methods have indicated that although the amount of oestrogen excreted by menopausal women is less than in those living a normal reproductive life, it is surprising that it still occurs at such a relatively high level considering that the menopause is a condition characterized by ovarian failure. Parkes in 1937 suggested that the adrenals might be the source of post-menopausal oestrogens. An accurate, sensitive and apparently specific chemical method by estimating separately oestriol, oestrone and oestradiol 17β has now been developed in Edinburgh by Brown. Confirmation of the bioassay work has been obtained in preliminary experiments using these methods.

Two theories have been put forward to account for menopausal symptoms. The first is the theory of gonadotrophin excess, and the second the theory of oestrogen lack; but there is now a good deal of evidence that the former is not correct. Even though the oestrogen withdrawal theory seems more likely, there are still several objections to this, and it seems that neither of the hormonal theories explains the cause of menopausal symptoms.

Dr. Thung pointed out that the involutionary changes in the mouse ovary are similar to those in man, the most characteristic of these changes being the decrease in the number of follicles until, finally, only a few degenerative follicles are left; however, there are some changes which take place in the ageing mouse ovary which are very different from those found in the ageing human ovary.

This is due to fundamental differences in structure between the two types of ovary. The human ovary has a connective tissue core, the medulla, around which lies a relatively thin cortical portion which contains the follicles and corpora lutea. By comparison, the mouse ovary contains very little interstitial tissue and no medulla: it is little more than a cluster of follicles and corpora lutea. Also, the mouse ovary during its reproductive period (abou one year) produces a much larger number of follicle both mature and atretic, than the human ovary in similar period. Moreover, each of these follicles destined to a shorter existence. The human ovary ageing becomes progressively more fibrotic, wherea in the mouse ovary very little fibrous scar tissue formed—the cells of the degenerating follicles simpl disintegrate and disappear. The pellicles surroundin the degenerating ova survive as crinkled remnant and often become calcified. In strains of mice su ceptible to amyloid degeneration, more parenchym is present in ageing ovaries; and hyaline infiltratio may occur, particularly in the corpora lutea, whic may afterwards also become calcified.

In ageing mouse ovaries, large phagocytic cell filled with lipo-fuscin pigment (ceroid) appear an increase in number with age.

These aged ovaries may still show some function activity; for example, an oestrous cycle persists i the vagina of the mouse (vaginal smear techniqu long after the loss of fertility, and these have in som cases been observed to persist even up to the momen of death. This suggests that some part of the ovar continues to secrete oestrogenic hormones. Th may, in fact, be the germinal epithelium, which n only becomes more obvious but also seems to have proliferative tendency in the old ovary, resulting i small ingrowing tubules and producing certain ce groups which look like small follicles without ova.

# WINTER OBSERVATIONS ON A ZONE OF CLIMATIC MODIFICATION IN THE NORWEGIAN ARCTIC

## By N. C. NEGRI

**Leader and Meteorologist, Lyngen Winter Survey Expeditio**

DURING the post-war period of exploration, n less than seven scientific expeditions visited th Lyngen Peninsula, 250 miles beyond the arct circle on the north coast of Norway. However, a these parties confined their observations to th summer months; consequently there was no information relating to the prevailing winter conditions i the region. By the autumn of 1954 the need fo such observations was such that the newly forme Mount Everest Trust Foundation agreed to spons a "comprehensive winter survey". The Roya Geographical Society approved the final plans, an supplied much of the necessary equipment.

This article summarizes the climatological observations made in a zone of modification at the hea of a fjord on the north-west coast of the peninsul The inner reaches of this fjord were separated fro the main valley by two spits and an island. Fo the purposes of comparison, the expedition established a full-scale meteorological station half a mil north of these spits.

The mountain basin south of the spits clearly ha an unusual local climate, for we observed the sal water within it freezing, although the temperature a the station was above 29° F. After a brief invest gation of the general conditions in the basin, w reached the conclusion that the cause of the phenomena was a cold air stream from the south. Thi much was obvious; but the task of locating the ource of this air stream was a complex problem, ith the normal difficulties of field-research increased y the extreme conditions of the locality, and the mited daylight. We decided that the only certain method of fixing the position of the source would be y establishing the relative situation of the lowest emperature in the basin at sea-level, and tracing he source from there. We accomplished this by ircumnavigating the basin, measuring the temperature at frequent intervals. Eventually we succeeded n compiling sufficient reliable figures to plot isoherms for the region. Simultaneously with these ourneys, we ascended the slopes of the mountains sing from the basin, in order to determine the ertical extent of the climatic zone. The inversions ecorded on all occasions showed the temperature at ,000 ft. to be 10° F. higher than that at sea-level. The curve of this temperature gradient indicated hat the rise took place mainly in the upper 500 ft.

All the temperature-recording journeys proved beyond doubt that the very lowest temperatures occurred at a point just south of the fjord-ice at the base of a wide defile leading to a glacier-filled cwm, at an altitude of 1,500 ft. As the mountain walls n either side of the defile reached heights exceeding ,000 ft., it was safe to assume that the glacier cwm nd the defile itself were both free from wind, and herefore unlikely to be affected by cold air currents rom the interior of the peninsula. It followed from this hat the source of the cold air stream was the glacier.

The sequence of events from the time that a parcel of cold air accumulates near the snout of the glacier can now be traced. By virtue of its greater density, the glacier-cooled air would push itself under any comparatively warm air in the vicinity, and flow down the subsidiary valley formed by the rock walls of the defile. On reaching sea-level, it would attain a state of almost complete stability, that is to say, there would be little or no convection within the air itself, or heat exchange between the snow cover of the basin and the air. In relation to the latter, it should be remembered that, for a climatologist working during the Arctic night, the polar nocturnal constant relieves him of problems of solar or terrestrial radiation.

Having reached the valley floor, the parcel of air would flow over the surface of the fjord-ice toward the open water in the north. As it approached the warmer air near the water, it would cease to be a evel stratum, and become instead a wedge of air, behaving in exactly the same manner as a macroclimatic cold front. The water in the fjord was always 20° F. warmer than the air from the south, and therefore a fog layer 5 metres thick and 3 metres above the surface of the water would form at the point of occlusion.

Our conclusion from the above was that, during winter months when the moderating factors of radiation and reflexion were set at nought by the absence of the sun, the local climate of the mountain basin was entirely dependent upon the glacier at the southern extremity of the fjord valley; also, that this modification of macroclimate was quite out of proportion to the relatively small area occupied by the glacier.

The significance of such an area is obvious when one considers the difficulties of studying the relationship between glaciers and climate in the lower atitudes of Europe, where the climatologist has to account for an extremely wide diurnal temperature-range and other complicating agents, such as nocturnal heat exchange, ablation of the snow, and erratic winds. All these disturbing influences are removed during the period after the winter solstice, and it is possible to obtain almost perfect continuity in climatic observations until the return of the sun in February. So it may be said that, in the glaciated areas of Arctic Scandinavia, the climatologist has a virgin field, easily accessible, and abounding in possibilities for winter research on a smaller, and consequently more accurate, scale than is at present possible in Austria or Switzerland.

# AUTOMATION IN THE SOVIET UNION

THE U.S.S.R. claims to have achieved the automatic factory, but little detail is available; more definite information, at least indicating some of the lines along which research in this field is proceeding or is contemplated in the Soviet Union, may possibly be found in reports of two recent conferences: one on the modern theory of machines, and the other on the progress of automation in the consumer goods industries—mainly food and textiles.

The first of these, reported in *Vestnik Akad. Nauk SSSR*, No. 12, 1954, is by I. I. Artobolevskii and co-workers, and is chiefly devoted to the paper they themselves read at the conference, with a few brief notes on some of the other papers. The meeting was organized by the Institute of Machine Construction (affiliated to the Academy of Sciences of the U.S.S.R.), and was an attempt to strengthen the scientific foundations of the machine construction industry.

Artobolevskii's paper emphasizes the importance of the theory of machines and mechanisms, especially in relation to the growing demands of automation. Discussing first of all the general theory, he thinks this is fully developed only in the case of prime movers, and as yet very imperfectly in other directions. A main factor to-day is the greatly increased speed of operation and general efficiency, the effect of which still requires close study. But the most important direction for the development of modern machine design is that of automatizing and mechanizing technological or industrial operations. In recent years in the Soviet Union many types of automatic machine have been evolved. Automatic and continuous production lines have been widely adopted. Most of the heavy and laborious operations in mining, metallurgical, building and other industries have been mechanized. Soviet scientists have discussed many fundamental questions relating to automatic machines and mechanisms. More especially they have outlined the general theory of the cyclogram automatics, analysed problems of regulation and control, suggested means and methods for design of individual types of mechanisms, and so forth.

Many difficulties in the theory of automatic machines still await discussion and solution. Among the fundamentals, for example, are the dynamics of free-flowing bodies or material to be mechanically ground, screened and conveyed; the dynamics of bending or flexing of fibres and threads in textile, cable-making and similar machines; the hydrodynamics of viscous liquids to be treated in separators, centrifugal or other; the aerodynamics of air currents in wind motors and the like, including the various kinds of pneumatic mechanisms. These matters and many others demand specialists in mechanics, physics and chemistry, and their close co-operation. The author also refers to the need for rationalizing the form or geometry of the working organs and tools in a wide range of varied operations. A valid theory of working processes and operation should form the basis of generalizing methods of tool-form design.

A study of power and kinetic characteristics is also essential, and needs carefully planned experiment, with the development of methods and instruments for recording movements, speeds, accelerations, forces involved, and capacities. An important part here will be played by the new electronic, acoustic and electromagnetic devices, radioactive isotopes, the piezo-effect and other means now being applied. Calculation and design of automatic machine units involves furthermore a precise knowledge of their "kinetic layout (scheme) in principle", and more specifically their operational cycles and relations.

The cyclogram theory requires further development, since the determination of one or the other working cycle depends not only on the particular process or function, but also on speeds and accelerations of the several units, and the forces actuating these. From analysis of all these characteristics a general cyclogram may be constructed, conforming to the optimum performance of the machine with minimum expenditure of power on unproductive wastes or losses and maximum equalization of torque on the driving shafts.

The author proceeds to analyse the various mechanisms taking part in the operations: driving, transmission, directing, controlling, speed variation, stopping, etc. Special reference is made here to the design of cam mechanisms of the three-dimensional type, with the complaint that, in their kinetic and other aspects, theory has been little developed in the Soviet Union. Much the same applies to lever mechanisms, to non-stepped drives—so important in automatic machines—and to other units. Research in hand in some institutes in these and some other fields must be both intensified and extended.

Some of the fundamental differences between automatic and non- or semi-automatic machines are noted. In the former, a control unit called a 'datchik' appears to be of primary importance. It has been variously designated by British engineers as a booster, a pickup, etc. By means of suitable 'datchiks', variations in such parameters as speed, pressure, temperature, volume or density, are transmitted to the appropriate controls. In general terms, the author refers to certain lines of progress in the Soviet Union in the matter of controls not only for solids, but also for other forms of product, in statistical controls and computers, in programming, and so forth.

Other matters discussed also in general terms include the effect of clearance or play in kinetic couples, resilience, forces of dry and lubricated friction—requiring new methods of study and experiment—and temperatures. The hydrodynamic theory of friction is said to be well developed on the mathematical side, but less so on the experimental. The author considers that one of the most important parts of modern machine theory relates to machines in series or aggregates. Hitherto it has been developed quite separately for prime movers on one hand and the operative machines on the other; but under modern conditions the boundary line between these two classes is sometimes quite obliterated. It is now essential to regard the aggregate as one entity.

Somewhat more definite, but still largely in gener terms, is an article in an earlier issue of *Vestnik Al* (No. 8, 1954) by N. N. Shumilovskii on some problem of automation in the Russian consumer good industries, primarily as a means of increasing outpu of these goods and removing some of the bias i favour of heavy industries that has lately marke Soviet economy. His article is based on a recen conference sponsored by the Institute of Automatic and Telemechanics in collaboration with Ministr of Consumer Goods Production. Some of the funda mental requirements for conversion to complet automation and the creation of the automatic factor are indicated. These include close examination o particular cases of complete automation, preferabl of a more or less standard type, so that the experienc gained can be widely applied.

Some of these basic problems were discussed in paper by V. A. Trapeznikov, with a certain amoun of detail in other papers read at the conference. B way of example, conditions in the cotton industr were considered, in its different divisions: spinning weaving and finishing. In the first there is a con tinuous production line, with almost complet mechanization; but there is scope for more automation. In weaving, automatic machines are mainl used, but certain difficulties still remain: maintainin constant (*a*) tensions of thread at various stages (*b*) temperature, level and viscosity of sizes, and (*c* moisture content of yarn; (*d*) automatic warning o flaws, and stoppage for breaks or completion of bale or wrong patterns, etc. Various manual operation remain to be mechanized and automatized: feedin yarn, joining ends, winding and cutting threads, an removing product. Automatic control is also widely used in finishing; but much scope yet remains. A few solution strengths are controlled: sulphuri acid, sodium hydroxide and hypochlorite; but ther is no suitable automatic control of moisture conten of fabric after drying. In printing, too, the superposing of different coloured patterns in multi-colou work, along with other operations, should be automatized. Continuous automatic lines with cascade electric drives should be developed, providing the required range of speeds and automatic control of tensions.

The problems are widely different in tanning. Here there may be forty to fifty operations, of which up to 60 per cent may be mechanized in the best Soviet factories. With the aid of conveyors, cranes, telpher lines, automatic loaders, etc., mechanization at least (automatic or not) could be raised to 90 per cent. Suggestions for automatic continuous production lines have already been put forward by inventors and innovators, with a series of mechanized units of a new kind. Measuring devices, automatic controls of humidity, of dyeing, drying, spraying and fixing have yet to be perfected.

The author proceeds to discuss the progress made in some of the food industries, where automatism is in various stages. During the past few years, breadmaking has been highly mechanized; but automatic controls are still lacking in respect of moisture content of dough, temperature and moisture in the ovens, level of dough in the kneaders, and in other directions. In the confectionery trades much also yet remains to be done, although it is claimed that an automatic device has been evolved for caramels, with pressure and temperature control, and with automatic discharge periodically during continuous operation of the vacuum cooker.

In dairy work, although mechanization is said to have reached an advanced stage, from which the transition to almost complete automation should be relatively easy, this has not been accomplished. The so-called Meleshin method of making butter is cited as an exception; the process is said to have many features of interest, though none of these is described. The production cycle-time is reduced from 20 hr. to 40 min.; the butter is of high quality and keeps well in storage. It ought not to be difficult to extend automation generally throughout the dairy and allied industries, at all events so far as concerns the control of fat, sugar and other ingredient contents.

In the oils and fats industry, modern plant has been more extensively adopted, including continuous instead of batch operation both in production of the oil and in its refining. Some progress is reported in the matter of automation, but methods are still imperfect in respect of controls for certain operations: determinations of oil and moisture content, automatic weighings and feeds. Reference is made to new devices for automatic quality-control of products and of filter-press operation based in some way on dielectric losses; but no details are given. W. G. Cass

# BASIC RESEARCH IN THE UNITED STATES

The concern which is felt in the United States over the increasing dependence of basic research upon Government support is reflected in three papers contributed to a symposium on the roles of Government, industry and the university in basic research. The symposium was held in Berkeley, California, on December 30, 1954, and the papers have now been published in *Science* (121, 781; 1955). Discussing the role of Government, P. E. Klopsteg, of the National Science Foundation, defines basic research as the systematic endeavour, without preconception, to increase our knowledge and understanding of Nature, and he suggests that, if this definition could be applied precisely, the Government funds given for this purpose, estimated at 116 million dollars, 120 million and 131 million dollars for 1953, 1954 and 1955, respectively, would be drastically revised downwards. Nevertheless, the Government contribution is now many times greater than before the Second World War, and without discussing all the implications of such dependence on Government support, apart from the possibility of an ultimate deterioration in the quality of research and of bureaucratic interference with the administration of institutions of higher learning, Mr. Klopsteg thinks that Government policy should seek to encourage greater support of basic research both by corporations and individuals. For this he suggests that the income-tax law pertaining to charitable donations should be revised so as to encourage donations by taxpayers to basic research by one of three methods outlined which provide strong incentives for giving.

While the Government would still have an important responsibility for the direct support of research in its own laboratories and for the support of such research at educational institutions and of large projects by team research, Mr. Klopsteg considers that the proposals he makes would check the trend towards almost exclusive dependence on Government support. Institutions would derive their major support from private donors and corporations. Research would be kept free, and the severity of many problems originating in the inadequacy of funds for higher education would be reduced.

Mr. M. E. Speght, of the Shell Oil Co., New York, discussing basic research in industry, gives the number of research workers in the United States as 450,000, of whom more than a third have a bachelor's degree. Expenditure on industrial research laboratories is put at 2,500 million dollars, of which 1,100 comes from Government sources, and about 150,000 persons are employed in such work. Taking the total man-power, research costs are estimated at 7,000–10,000 dollars a year; but for professional workers the medium costs are about 15,000–25,000 dollars a year. Defining basic research as scientific inquiry carried on, not under pressure of immediate needs or in hope of quick profit, but with reasonable hope of some eventual payment, Mr. Speght estimates that industry employs some ten thousand people, four thousand of whom are professionals, and spends a hundred million dollars a year on such work, of which about ten million dollars is in support of research in universities and other non-profit institutions. The limits on basic research are most likely to be set by the number of worth-while ideas that the scientific worker of the organization can propose; but Mr. Speght agreed that a greater investment in the search for new knowledge is necessary if the present rate of technological advance is to continue. He also believes that industry's contribution, particularly to universities and their affiliated research institutes, will continue to increase, and he does not think that this trend can be interrupted by a business recession.

Discussing the role of the university, Prof. K. S. Pitzer recognized the inadequacy of university budgets in the United States even for the present level of basic research, and welcomed the effect of all Government aid to research. The administration of Government funds for this purpose by various Government agencies has been excellent; but he criticized the practice of breaking down the funds into very small units tied closely to particular projects. Funds made available to the universities on a broad basis are used very much more effectively, and he thought that both Government and industry could contribute to improved methods in the future.

# GRANTS TO STUDENTS IN TRAINING COLLEGES IN BRITAIN

The Working Party on Grants to Training College Students, on the recommendations of which the increased grants recently announced by the Minister of Education are based, was appointed in January 1954, with Mr. A. E. Miles Davies as chairman, to work out the costs which students at training colleges in Great Britain are called upon to meet and which are known to vary substantially and merit examination; the amount which parents or students should be required to contribute; the distribution of the balance over all local education authorities; and the reduction of the range of "incidental expenses". The then Minister of Education, Miss (now Dame) Florence Horsbrugh, in appointing the Committee, made it clear that she could not entertain any suggestion for relieving local education authorities of their present responsibility for sharing this expenditure with the Exchequer in the usual proportions. Accordingly, the more radical proposals of the National Union of Students and of Political and Economic Planning fell outside the terms of reference of the working party; it may be noted that Prof. R. Pascal, of the University of Birmingham, demurred at these latter proposals in an article in the *Universities Review* last October and gave as his main reason that they would abolish the association of the local authorities with the universities in this connexion—an association which, like the Association of University Teachers in its "Report on University Development, 1944", he believes to be of real value.

The report of the working party* opens with a brief survey of the present system and then discusses the two main criticisms. The first is that the grants for personal expenses which are made to about 60 per cent of all students, usually ranging between £20 and £50, but sometimes exceeding £80, are now generally considered to be inadequate; the gross cost to local education authorities is about £510,000, and the Exchequer meets some 60 per cent of this. Some suitable candidates are accordingly deterred from entering upon a course of training, and others, apart from completing their course only at the cost of hardship to themselves and their parents, are adversely affected by uncertainty about their resources, by enforced parsimony in their outlay on books and other necessary items or loss of social and cultural opportunities for development.

Secondly, there are wide variations among the education authorities in the amounts of assistance they offer and their arrangements for relating grants to income. Some limit their assistance to students with net parental income less than £500, and under the schemes of some thirty authorities a parental net income somewhat above £500 may disqualify a student from receiving any assistance towards personal expenses. About half the authorities make grants to students whose parental net incomes exceed £500, even though these students are at the same time required to pay a student's contribution under the Ministry's regulations, and the scales of some fifteen authorities provide for grants at net incomes exceeding £900. One or two authorities do not exercise their powers to make grants, and a few offer loans instead of grants or in conjunction with them.

In both these respects the financial position of training college students compares unfavourably with that of students at universities who are being assisted either by the Ministry or by local authorities. It was common ground, from the outset, among members of the working party that the present arrangements are vulnerable to complaints of unjustifiable variation, and investigation of the amount of personal expenses amply confirmed the criticism of general inadequacy. Their inquiry revealed an unexpectedly wide range of variation in estimates of personal expenses taken as a whole and for particular items such as clothing; but they formed the opinion that the wide diversity of practice among the training colleges in their interpretation of their responsibility for providing tuition, board and lodging, which leads to such variation, is undesirable, and they are convinced that the colleges should jointly review their arrangements in this respect with the view of adopting broadly similar practices in the division of expenditure between themselves and their students.

In making its proposals for a standard rate of grant, the working party envisages a grant which, for personal expenses, at the maximum, should cover the essential needs of students of no means, and for vacation expenditure should reasonably involve some contribution from their families towards their support in the family household. On these considerations and on the basis of the available evidence, it recommends that a total grant of £160 throughout the period of the two-year course should be generally adopted as the standard maximum grant, providing adequately for necessary personal expenses for a student of no means and also a reasonable contribution towards maintenance during vacations. For a student of no means it also recommends that the standard grant for personal expenses should be increased by an amount assessed individually to cover the ascertained cost of travel between home and college at the beginning and end of each term. Day students who live at any considerable distance from the training college should also be eligible for a similar allowance towards the cost of their daily travel. The standard rate of grant should be subject to triennial review at the same time and by the same machinery as the review of the university standard figures of maintenance. In view of the heavier expenditure incurred in the student's first year, it recommends that £30 of the total grant should be paid as an initial allowance before the student enters college and the rest in two equal annual instalments of £65.

The working party also considered the needs of women students attending three-year specialist courses in housecraft or physical education and a request for a higher annual rate by representative principals from the colleges providing the courses. The working party reached the conclusion that, for a housecraft student, a total grant of £240, £45 being given as an initial allowance and the remainder in three annual instalments, should be adequate, but for students of physical education it recommends an initial allowance of £55 and three annual grants of £65. For certain groups of one-year students it recommends a maximum grant for personal expenses at the rate appropriate to the first year of a two-year course, namely, £95. While for students who proceed directly to a supplementary course on completing their normal training, a maximum standard grant for personal expenses of £65 should be reasonable, for serving teachers the only satisfactory form of financial assistance is secondment on salary for the duration of their training, and general adoption of this practice is recommended.

It is clearly desirable that a system of standard grants for personal expenses should be accompanied by a uniform method of assessing parental contributions, and the working party finds in the income scale used for awards at universities made by the Ministry and by local education authorities a suitable general pattern for assessing a parent's capacity to contribute towards the cost of his children's education and training. Moreover, adoption of a single income scale for assessing grants for personal expenses would enable arrangements for both types of grant to be assimilated into a single scale, and the parental contribution would act in the first instance to reduce the amount of grant payable for personal expenses: a contribution towards boarding costs would fall due only when the assessed contribution exceeded the maximum of the grant for personal expenses. Under the scale, it would also become necessary for the home' local education authority to undertake the ntire responsibility for assessment, and the working party points out that administration of this system of assessment would be simplified by adoption of a uniform standard boarding fee at all training colleges.

---

* Ministry of Education. Report of the Working Party on Grants to Training College Students. Pp. 28. (London: H.M.S.O., 1955.) 1s. net.

The total additional cost of these proposals, over and above the present annual expenditure on grants for personal expenses of £510,000, is estimated at about £1,400,000, of which £892,000 would fall on he Exchequer and £508,000 on local rates. The financial arrangements for teacher training as a whole would be simplified, and the working party also uggests including in the one pattern the personal and dependant's grants paid by the Ministry to ome older one-year students, and also grants to day tudents towards the cost of their home keep while attending college, thus bringing the annual expenditure covered by the proposals to about £2,080,000.

# BARLEY ROOTS: NITROGEN ASSIMILATION AND RESPIRATION

IT has already been shown that the respiration of barley seedlings is closely dependent on the supply of nitrogenous nutrients. In culture solutions containing ammonium salts or nitrates, barley seedings show a rapid increase in carbon dioxide production, this being initially largely confined to the root system. The relation between respiration and the assimilation of nitrogen by roots has now been more fully explored by A. J. Willis and E. W. Yemm (*New Phytol.*, 54, 2, 163; 1955). These investigators have presented and discussed a considerable series of observations and have reached the following conclusions.

The assimilation of nitrogen in excised roots of barley leads to high rates of respiration. The greatest respiratory increases are shown by roots deficient in nitrogen and rich in carbohydrate. Roots cut from seedlings which are grown under conditions of nitrogen deficiency and which have not exhausted their endosperm reserves show smaller carbon dioxide increases when external sources of nitrogen are supplied than roots from older seedlings. Increases in both carbon dioxide production and oxygen uptake result from treatment of roots with ammonium salts, nitrates, nitrites and hydroxylamine, although there are secondary toxic effects of hydroxylamine. The form of the respiratory response depends upon the source of nitrogen supplied: ammonium salts give rise to very rapid increases in gaseous exchanges, while with nitrate the greatest increases are not shown until about 9 hr. after its addition to the roots. The effects of other anions and cations supplied with the nitrogen source are small. At very low concentrations of the nitrogen supply the respiratory increase is limited, and all the available nitrogen is exhausted from the culture solution.

These effects of nitrogen compounds on respiration are different in form and magnitude from salt respiration. The salt respiration of roots grown under the conditions used here has been demonstrated to be very much smaller than the respiratory increases found on supplying the roots with inorganic nitrogen. Measurements of respiratory quotients and evidence from direct analysis indicate that nitrogen is rapidly metabolized in the roots, and that high rates of respiration are associated with the synthesis of nitrogen compounds in the tissues.

# THE EFFECT OF CERTAIN DRYING CONDITIONS ON THE PUTREFACTION OF CATTLE HIDES AND GOATSKINS

IT is unfortunately true that, after flaying, African prepared hides and skins are left lying in heaps for an unnecessarily long time in wet and filthy conditions, and it is not surprising that putrefactive damage forms one of the more common blemishes of East African hides and skins.

Putrefactive damage can be diminished by measures which will decrease the bacterial population. One of the most effective ways of preserving hides and skins is to reduce their moisture-content to a level where bacterial action and growth become impossible. Air-drying is the most commonly used method of preservation in East Africa because (*a*) it is a quick, cheap and easy method for African conditions, (*b*) chemicals are not generally available for salting or pickling, (*c*) transport charges on dried hides and skins are lower than on salted or pickled stock, and (*d*) no special storage or transport facilities are required.

A series of experiments was carried out by Dr. R. L. Sykes to determine the extent to which putrefaction could be controlled by certain methods of drying (*Colonial Plant and Animal Products*, 4, No. 3; 1954).

The traditional local African method of air-drying is to peg hides and skins on the ground, flesh-side up, to dry in the sun. The products, which in the past were called 'sun-drieds' and are now known as 'ground-drieds', are dirty, unattractive articles shunned by most tanners because, not only are they difficult to handle and soak back, but also because they give rise to unpredictable and serious losses during processing. Up to twenty-five years ago the bulk of East African hides and skins were prepared in this manner; but, as the result of tests on drying procedures carried out by a few pioneers, certain tanners realized that, when dried in sheds, the resulting 'shade-drieds' possessed superior leather-producing values and gave significantly lower tannery losses. The difference was so outstanding that controlled tests were carried out in 1932 by the Imperial Institute and the Kenya Veterinary Department. These experiments confirmed the earlier tannery observations, and as a result the drying of hides and skins in open-sided sheds after suspension within a vertical rectangular frame was advocated.

From its 1932 tests the Imperial Institute drew the important conclusion that the essential factor in air-drying was suspension and not shade.

The 1932 trials also led the Imperial Institute to suggest that hides could be dried in the open provided the heat from the meridian sun could be tempered by orientating the plane of the hides in an east-to-west direction and by inclining it to the vertical so that the plane lay parallel to the rays of the midday sun.

It was not always easy to make uneducated producers understand what was required, and, since the midday sun in East African latitudes strikes a vertical plane obliquely, it was found more practicable to advocate vertical frames when drying hides in the open.

Neither this experimental evidence, nor the fact that many Uganda hides are so satisfactorily dried in the open in the wet season that tanners cannot distinguish them from shed-dried articles, have convinced the more conservative critics, who are still doubtful whether drying in the open can ever be successful in moist humid climates. The experiments have shown that, under a variety of climatic conditions, some being most adverse, it is possible to dry cattle hides and goatskins satisfactorily. Provided the hides and skins are properly suspended for drying, the site, the presence of shade, or the method of suspension has little effect on the incidence of putrefactive damage. Similarly, under these conditions, a short delay of one hour in the cleaning, after flaying, has no effect on quality.

The majority of the putrefactive damage which occurs in hides and goatskins is avoidable and must be attributed to the carelessness or ignorance of the owner or producer. Any reasonably quick method of drying by suspension can thus be relied upon to eliminate putrefactive damage to hides and skins and no insuperable difficulty should be associated with normal drying methods in African reserves. This suggests a method by which a campaign for hides improvement, supported by the necessary legislation, should be able to develop the confidence of native producers and eliminate putrefactive damage almost completely.

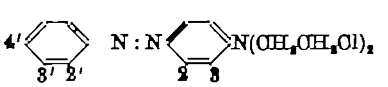
# REDUCTION OF CYTOTOXIC AZO COMPOUNDS BY HYDRAZINE AND BY THE XANTHINE OXIDASE–XANTHINE SYSTEM

By DR. W. C. J. ROSS and G. P. WARWICK
The Chester Beatty Research Institute (Institute of Cancer Research: Royal Cancer Hospital), London, S.W.3

IT has been shown[1] that many aryldi-2-halogenoalkylamines can inhibit tumour growth, provided that the compound contains halogen atoms of a certain level of chemical reactivity[2]. In attempts to obtain derivatives of greater selectivity of action, compounds have been prepared which have chlorine atoms of low chemical reactivity but which could be activated by a change in the molecule such as could readily occur *in vivo*. Derivatives of the azo-compound (I) are suitable compounds for trial, since the parent substances contain chlorine atoms of low reactivity, whereas reduction products (hydrazo-compounds or amines) would be more reactive. It was hoped that such reduction of the azo-linkage would occur in the organism—compare the reduction of 'Prontosil' to give sulphanilamide[3]—but that it would not take place equally well at all sites and that some measure of specificity of action would result.



$$C_6H_5N:NC_6H_4N(CH_2CH_2Cl)_2 \quad (I)$$

A number of these azo-derivatives of 'aromatic nitrogen mustards' have already been described[4] and a long series of derivatives has now been prepared by us (unpublished work). Many of these compounds are effective inhibitors of the growth of the transplanted Walker rat carcinoma (personal communication by Prof. A. Haddow), and this suggested that the postulated reduction of the azo-linkage did, in fact, occur.

In order to obtain further evidence for the proposed mechanism of activation, an attempt has been made to correlate the ease of reduction of an azo-compound (I) with its biological activity. Since most of the compounds were sparingly soluble in water, the rates of reduction in 50 per cent aqueous alcohol at 24° C. and at *p*H 8 were initially investigated. Of the reducing agents examined, the most consistent results were obtained using hydrazine. The reaction, which was followed by measuring the characteristic light absorption at 400 mμ due to the azo-compound, was found to be first-order with respect to azo-compound, and in Table 1 the relative rates of reduction referred to the parent substance (I) are given. It can be seen that there is a definite indication that biological activity is associated with reducibility. Two apparent exceptions, the 2'-methyl- and 2'-carbomethoxy-derivatives, are almost certainly converted into the more readily reduced 2'-carboxy-derivative *in vivo*.

It was next felt desirable to ascertain whether any naturally occurring enzyme could effect the reduction of an azo-linkage; and since various dyestuffs are known to act as hydrogen acceptors in the xanthine oxidase–xanthine system, it seemed logical to examine this enzyme. In this case it was necessary to employ purely aqueous solutions, and accordingly the rates of reduction of various acidic derivatives, which have adequate water-solubility in pyrophosphate buffer at *p*H 8·2, were examined at 24° C. under anaerobic conditions. The suggestion to use this enzyme arose in discussions with Prof. F. Bergel, Mr. P. Avis and Mr. R. C. Bray, who kindly made available a concentrate of xanthine oxidase from cow's milk (stage *M5*) prepared as described by Avis *et al.*[5]. It was established that the azo-compounds

ere unaffected by the enzyme alone or by xanthine one under the standard conditions.

The correlation between reducibility and biological tivity shown in Table 2 is even more striking. The tes of reaction are expressed in this instance as rcentage reduction of the azo-linkage in a given me. One of the outstanding exceptions in Table 1—e 2'-sulphonic acid derivative—is now seen to be it slowly reduced by xanthine oxidase. The only iomaly in Table 2 is the 2-methyl-4'-carboxy-rivative, and here again it seems probable that idation of the methyl group to a carboxyl group ill occur *in vivo*. It has, in fact, been shown that per cent of the 2 : 4'-dicarboxy-derivative is reduced ider the standard conditions.

The implication of a flavin–adenine–dinucleotide enzyme in the *in vivo* reduction of azo-linkages has en discussed by Miller and Miller[6], and it is now ggested that xanthine oxidase may be the enzyme volved. It is realized that other dehydrogenases ay be able to effect the reduction, and this point under investigation. The protective action of etary riboflavin in butter yellow carcinogenesis uld be a consequence of increased xanthine oxidase tivity which converts the dye into relatively active reduction products. Our *in vitro* experiments dicate an initial formation of hydrazo-compounds with both hydrazine and xanthine oxidase, since azo-compounds are re-formed on oxidation with iodine. Eventually this property is lost and, in the later stages of the reaction, fission of the molecule to give amines probably occurs.

If xanthine oxidase is the enzyme involved in the reduction of azo-compounds, it should be possible to increase the effectiveness of carcinogenic azo-dyes by simultaneous administration of known xanthine oxidase inhibitors, and also to increase the effectiveness of growth-inhibitory azo-'mustards' by suitably increasing the xanthine oxidase content of the tissues, for example, by increased riboflavin and protein intake. Those azo-compounds which are activated in the manner proposed should be particularly effective against neoplasms in which xanthine oxidase content is high, for example, in hepatomas[7]. It is hoped to test these points in the near future.

Full details of the preparation of the various azo-compounds and the reduction studies will shortly be published elsewhere.

This investigation was supported by grants to this Institute from the British Empire Cancer Campaign, the Jane Coffin Childs Memorial Fund for Medical Research, the Anna Fuller Fund, and the National Cancer Institute of the National Institutes of Health, U.S. Public Health Service, and was carried out during the tenure of an overseas C.S.I.R.O. research studentship by one of us (G. P. W.). We thank Prof. A. Haddow for permission to quote the results of tumour-growth inhibition studies, and Prof. F. Bergel for his interest in this work. [April 4

# OCCURRENCE OF TECHNETIUM-98 IN NATURE

By EDWARD A. ALPEROVITCH* and J. M. MILLER

Chemistry Departments, Columbia University, New York, N.Y.; Brookhaven National Laboratory, Upton, N.Y.

WE wish to present a preliminary report of results obtained in the course of a systematic arch[1] for long-lived technetium-98[2] in terrestrial aterials. This investigation was undertaken in an tempt to shed some light on the cosmological and trophysical[3] problems raised by recent observations technetium in the sun[4] and several stars of spectral pes *S* and *M*[5].

In view of the expected low abundance[1] of the ld–odd nucleus $^{98}$Tc, a highly sensitive method of tection, neutron activation analysis, was chosen. pon exposure to slow neutrons, a sample containing chnetium-98 will, by the $(n,\gamma)$ process, yield tech-tium-99*m*, which can be readily identified by its 6-hr. lf-life and 140-keV. γ-ray. The formation of this tter isotope may be regarded as proof of the presence of technetium-98, if its production by three alternative processes can be ruled out:

(1) $^{98}\mathrm{Mo}(n,\gamma)^{99}\mathrm{Mo}$, followed by $^{99}\mathrm{Mo} \rightarrow {}^{99m}\mathrm{Tc} + \beta^-$

(2) $^{99}\mathrm{Tc}(n,n')^{99m}\mathrm{Tc}$

(3) $^{99}\mathrm{Ru}(n,p)^{99m}\mathrm{Tc}$.

It is imperative for this reason that the concentrates to be isolated from selected minerals[1] be free of all traces of molybdenum, ruthenium and $2 \times 10^5$-year technetium-99. Since many other elements also interfere by the formation of γ-emitting activities, the following separation factors are required: Mo $\sim 4 \times 10^{10}$; Re $\sim 10^{10}$; Ru $\sim 10^{9}$; 59 other elements, $10^{6}$–$10^{11}$.

A procedure meeting these requirements was developed by a combination of anion-exchange chromatographic and distillation techniques. The

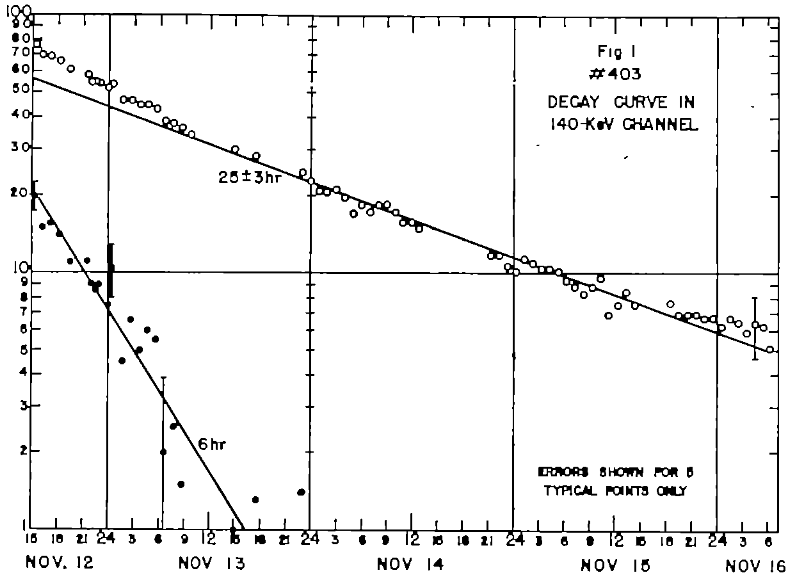

Fig. 1

minerals were dissolved by means of a fusion with sodium hydroxide and peroxide, and the sulphides of group II elements, along with any technetium present, were precipitated by hydrogen sulphide from acid solution. The sulphides were dissolved in a mixture of nitric, sulphuric and phosphoric acids, and the solutions steam-distilled under conditions in which technetium is known to be volatile. The distillate was then processed on 'Dowex-1' anion-exchange columns, and rhenium removed by elution with 0·2 *f* perchloric acid. The final concentrate, carried on copper sulphide or as mixed ammonium salts, weighing 0·1–1 mgm., was irradiated in the Brookhaven reactor for 12–70 hr. at a neutron flux of (2·4–3·6) × $10^{12}$ neutrons cm.$^{-2}$ sec.$^{-1}$. After irradiation, the copper was removed by cation exchange; the technetium, along with any molybdenum present, was co-precipitated with copper sulphide (procedure *A*), and counted with a scintillation spectrometer. In later work, the sample was processed on an anion-exchange column after the irradiation, and since technetium and molybdenum are separated in this step, a separate check for molybdenum was necessary. To accomplish this, the molybdenum was either carried on copper sulphide (procedure *B*), a method that was shown by separate tracer experiments to give a quantitative yield of molybdenum, or the molybdenum was carried o molybdenum sulphide (procedur *C*). In the latter case, a know amount of inactive molybdenur was added to the irradiate sample before any chemical prc cessing, and the final yield c molybdenum determined b chemical analysis. By means c this last procedure, the forma tion of technetium-99*m* fror molybdenum-99 could be rule out with absolute certainty, prc vided the isotopic exchange be tween irradiated and non-irrad ated molybdenum carrier wa complete.

Of twelve samples examine thus far, six gave positive result and two gave negative results in the remaining four cases th identification was uncertain. summary of the results is give in Table 1; a typical deca curve is shown in Fig. 1. Th data presented in Table 1 sho that: (*a*) in all cases a contaminating activit such as zinc-69 or arsenic-76 formed through neu tron capture by impurities from the resin and/c reagents makes a contribution to the countinç rate in the 140-keV. channel of the scintillatio spectrometer; (*b*) contamination with molybdenur 99 makes a contribution to the observed technetiur 99*m* activity in several experiments; but th contaminant was absent in five samples in whic technetium-99*m* activity was definitely identifiec and was not enough to account for all the tech netium-99*m* observed in a sixth sample.

The latter statement depends upon the assumptio that any molybdenum contamination present i these six runs behaved in the same manner a molybdenum tracer employed in experiments pe formed to check procedures *A*, *B* and *C*; th assumption is supported by the results in exper ments 396 and 410. The levels of the other cor taminating activities were generally sufficiently lo to avoid any serious difficulty in the resolution c the composite decay curves.

In the first phase of this work it had to be estal lished whether or not technetium-99*m* is produce by neutron activation of samples expected to contai technetium-98. The results obtained thus far hav proved this beyond doubt, for both radiation an

Table 1. SUMMARY OF NEUTRON ACTIVATION RESULTS

* Chemical procedures used after irradiation: (*A*) no separation of molybdenum and technetium carried out after irradiation; (*B*) moly denum and technetium separated by anion exchange after irradiation; molybdenum recovered by copper sulphide precipitation; (*C*) moly denum and technetium separated by anion exchange after irradiation; molybdenum recovered by molybdenum sulphide precipitation.

decay characteristics of the short-lived activity were repeatedly determined and found to agree very closely with those for technetium-99*m*. In the second phase, however, it had to be shown that the activity was produced by the $(n,\gamma)$ reaction with technetium-98, and by no other process. We do not yet regard this phase of the work as completed, though the most plausible explanation of the internal consistency of the results suggests the presence of long-lived technetium-98. It is interesting to note that in a recent communication[6] Herr reports the detection of technetium-99*m* in the neutron activation analysis of a molybdenite; it is, however, not clear that the technetium-99*m* activity observed was formed from technetium-98; it may well have arisen from molybdenum-98 or technetium-99 contamination in the sample.

We are planning to carry out more neutron-activation analyses and to verify their results by independent methods such as mass spectrometry and emission spectroscopy. This work was supported in part by the U.S. Atomic Energy Commission. We hope to publish a detailed account of it in due course.

# THE CONTRACTILE VACUOLE OF PARAZOA AND PROTOZOA, AND THE GOLGI APPARATUS

By PROF. J. BRONTË GATENBY
Trinity College, Dublin
AND
DRS. A. J. DALTON and M. D. FELIX
National Institutes of Health, Bethesda, Maryland

SAVILLE KENT[1] stated that "the peculiar flagellate sponge cells exhibited a very significant Protozoic feature in the possession of two or more posteriorly located, rhythmically pulsating contractile vesicles". In *Ephydatia* and *Spongilla*, Margaret Jepps[2] found contractile vacuoles in granular, hyaline, spicule-forming and collar cells, in the latter anteriorly located, however. Jepps studied various marine sponges, *Sycon*, *Grantia*, *Leuconia*, *Achinoe*, *Oscarella*, *Reniera* and *Halichondria*. She states, "In none of these sea sponges was a vacuole seen to contract in any cell whatever". Contractile vacuoles do, however, occur in some marine Protozoa.

Jan Hirschler[3], using the Kopsch and Sjövall methods (osmic acid reduction), described, as the Golgi apparatus of *Spongilla*, dictyosome-like bodies in the site of the contractile vacuole of Jepps. Hirschler did not know of the observation of Saville Kent, and thus unfortunately missed directing attention to the fact that the cortex of what seems to be the contractile vacuole in the freshwater sponge is specifically osmiophile, like the Golgi apparatus of the *Ciona* gut epithelium which he had studied at the same time by osmic methods.

It was left to D. Nassonow[4] to show that, in *Chilodon*, *Dogielella*, *Paramecium*, etc., the site of the contractile vacuole is the place of reduction of osmium tetroxide. Nassonow pointed out that in various metazoan cells (*Hydra*, *Axolotl*), a ring-form Golgi apparatus closely resembling the protozoan osmiophile ring-like surround of the contractile vacuole can be shown to exist. Nassonow considered that the cortex of the excretory apparatus of Protozoa, etc., was lipoid.

It has been shown by Dalton and Felix[5] that the metazoan Golgi apparatus typically consists of three components: (1) a group of long smooth double membranes; (2) clusters of small granules averaging about 400 A. in diameter, frequently showing an intimate association with the double membranes (these two components together form the cortical substance); and (3) a chain of large vacuoles arranged in the form of an open-sided cylinder. These vacuoles are not present in all cell types. The argentophily and osmiophily of the Golgi apparatus relate primarily to the small granules and the double membranes, although in some cells and under certain conditions the contents of the vacuoles are osmiophile.

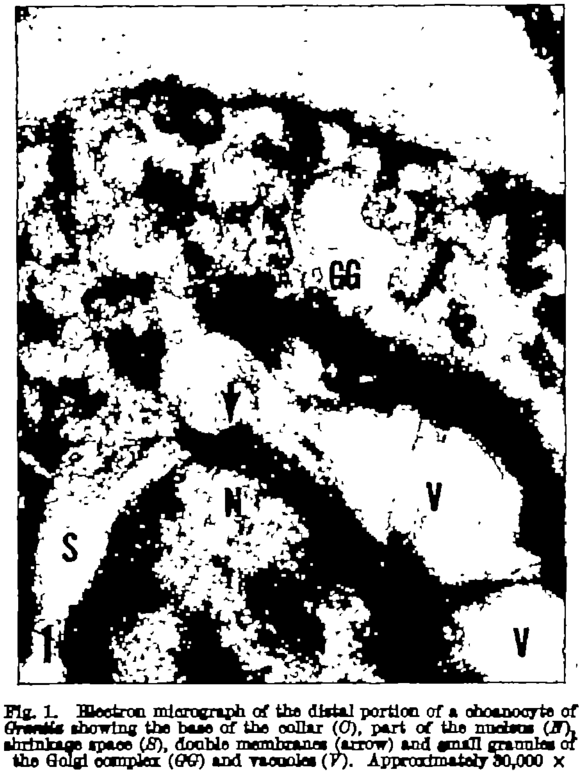

Fig. 1. Electron micrograph of the distal portion of a choanocyte of *Grantia* showing the base of the collar (*C*), part of the nucleus (*N*), shrinkage space (*S*), double membranes (arrow) and small granules of the Golgi complex (*GG*) and vacuoles (*V*). Approximately 30,000 ×

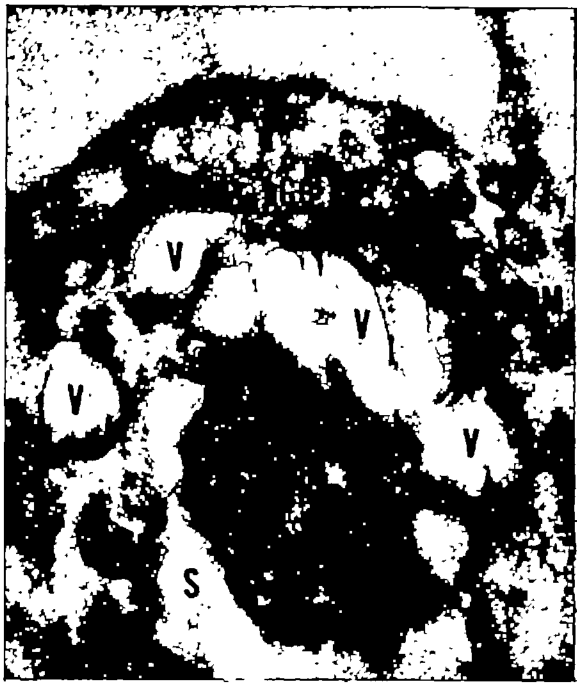

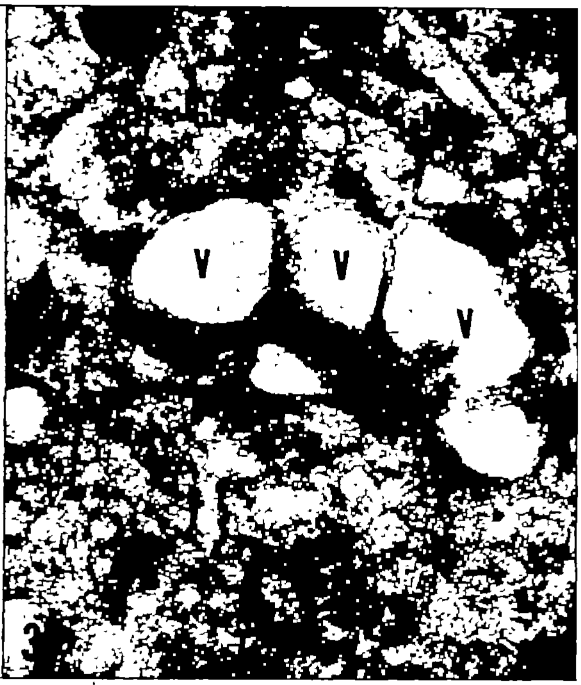

Fig. 2. Electron micrograph of a part of the same cell as in Fig. 1 at a different level, showing apparently separate vacuoles and mitochondria (*M*) with indistinct internal membranes. Other labels the same as in Fig. 1. Approximately 30,000 ×

Fig. 3. Electron micrograph of part of the Golgi zone of an epithelial cell of the epididymis of the mouse showing a marked similarity to the Golgi apparatus of the choanocyte (Fig. 1). The small granules appear to be continuous with the double membranes at some points (arrow). Labelling the same as in Fig. 2. Approximately 30,000 ×

The accompanying electron microscope photographs were made at Bethesda, Maryland (by A. J. D. and M. D. F.), from material fixed in buffered osmium tetroxide and chrome-osmium and received from Dublin (J. B. G.). Owing to the presence of spicules, the sectioning of the sponge material was very difficult. Figs. 1 and 2 of the marine sponge *Grantia compressa* show, at the outer end of the cell, the collar (*C*). The nucleus (*N*) has become shrunken on the left, leaving a space (*S*). Above the nucleus is the Golgi apparatus which, in the upper part of the photograph especially, shows a remarkable resemblance to the electron photographs of the epididymis (Fig. 3)[4,5,6]. There is a wall of double membranes and scanty Golgi granules (*GG*). In Fig. 2, we have confirmation of the observations of Jepps and Tuzet that several vacuoles can exist in this region. On the left of this figure, there is an apparently isolated vacuole (*V*) and at the lower right another partly shut off vacuole (*V*). At *GG* are examples of the scanty Golgi granules. At *M* are spherical mitochondria showing rather indistinct internal membranes. Besides the mitochondria, there are various granules of a smaller size of unknown nature. The Golgi apparatus of the choanocyte appears to have a spirally disposed inner cortical band.

We have also examined the contractile vacuoles of *Vorticella* sp. and the canals of the contractile vacuole of *Paramecium aurelia*. The osmic-reducing radiating canals are lined by a distinct, apparently single layer. Outside this, the osmiophile substance appears to be formed of a spongy branching network of short double membranes. Near the periphery of this zone are groups of small vacuoles. The cavity of the canal contains no formed material, and this also applies to the Golgi apparatus of the sponge *Grantia*. In the case of the contractile vacuole of *Vorticella* sp., the vacuole in partial systole contains a small cavity surrounded by a spongy mass of double membrane very similar to that of the cortex of the vacuol canal of *Paramecium*.

In conclusion, it can be stated that the electro photographs of the sponge Golgi apparatus closel resemble those of the metazoan cell Golgi apparatu This point of similarity is further strengthened by th osmiophily of the cortical substance on both, th presence near both of the small Golgi granules, an by the primitive form of dictyokinesis which has bee described in sponges, and in the contractile vacuol cortex of certain flagellates[7]. In 1933 Odette Tuzet showed that the acrosome of *Reniera* is formed i contact with a spherical body identical with th invertebrate dictyosome: all other types of spong cells studied with Golgi-apparatus methods by Tuze had one or more typical dictyosomes arranged i cells as the contractile vacuoles drawn by Jepp Thus from the freshwater sponge, through th marine sponge, we can link up the contractile vacuol and Golgi apparatus in metazoan cells. While th spongy cortical short branching material of th vorticellid contractile vacuole does not at first appea to resemble closely the lamellated membrane of th sponge, the substance of the cortical material i *Vorticella* is formed of double membranes; more wor on other Protozoa may supply the necessary intermed iate stages. A further account of this investigatio is being published elsewhere. [March 1

## Erosion of Surfaces by Liquid Drops

The question of erosion of aircraft surfaces due o flight at high speed in rain has for some time been he subject of study at research establishments both n Britain and in the United States.

To study the fundamental mechanics of the erosion rocess an apparatus is required which will reproduce he high-speed impact between a single drop and surface. Due to the low relative speeds at which ater drops shatter[1], difficulty is experienced in ccelerating a water drop of the size occurring in ain to the speeds at which surface erosion occurs above 400 ft./sec.). The alternative method of hooting the surface at a stationary drop has been sed in an apparatus described below which has been eveloped at the Royal Aircraft Establishment.

A projectile, the flat nose of which forms the surface o be studied, is fired from a compressed-air gun at a rop of water suspended on a fine web composed f a solution of 'Perspex' in aniline. After striking he drop the projectile is decelerated in an energy-bsorbing tube in such a way that the imprint of the rop on the surface is not damaged.

Fig. 1 is a diagram of the apparatus. The gun is red by rapidly opening a valve actuated by a large-iameter piston. It has been found that accurate ontrol of the projectile speed can be obtained by arying the air pressure in the gun, and speeds up to 00 ft./sec can be achieved. The technique of susending the droplet was suggested by Mr. W. R. ane, of the Chemical Defence Research Establishment, Porton, and provides a method of accurately placing a drop of any desired size. The energy-absorbing system comprises soft aluminium washers separated by spacers, the hole in the washers being larger in diameter than the flat impact surface of the projectile nose. The energy of the projectile is expended in passing through and deforming the washers. For some materials comprising the impact surface, such as metals, the washer system can be replaced by light pads of cotton wool, which do not damage the surface, placed at intervals along the tube.

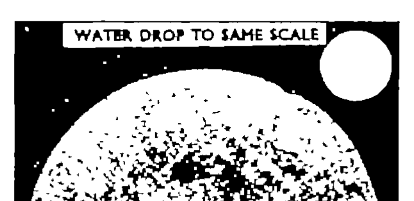

Fig. 1. Diagrammatic arrangement of apparatus. Crown copyright reserved

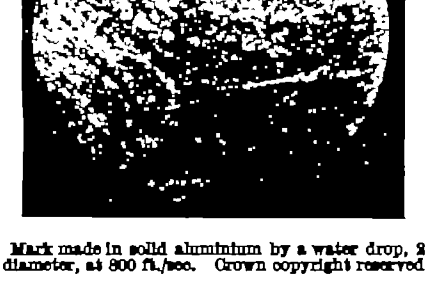

Fig. 2. Mark made in solid aluminium by a water drop, 2·5 mm. diameter, at 800 ft./sec. Crown copyright reserved

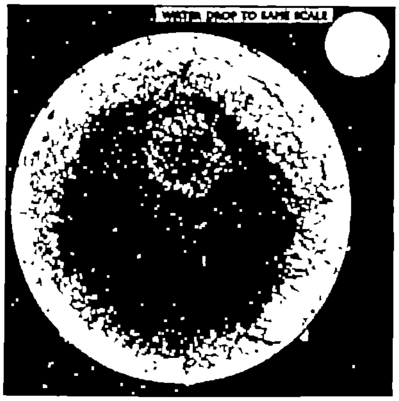

Fig. 3. Mark made in a wax layer by a water drop, 2·5 mm. diameter, at 580 ft./sec. Crown copyright reserved

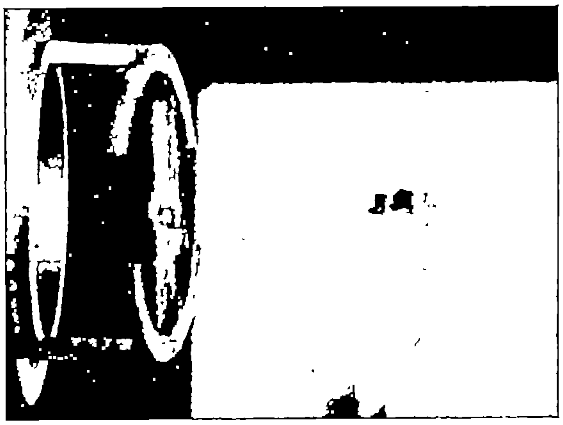

Fig. 4. Drop suspended on web. Crown copyright reserved

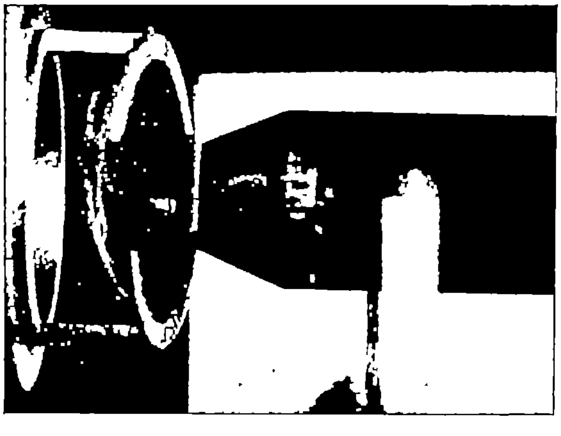

Fig. 5. Free drop before impact with projectile. Crown copyright reserved

Basic research with this apparatus is only about to start; but its possibilities are shown in the accompanying photographs, Figs. 2, 3, 4 and 5. Fig. 2 shows the impression made in solid aluminium by a 2·5 mm. diameter drop at 800 ft./sec., the depth of impression being approximately 1/1,000 in. Fig. 3 shows the annular crater made by a 2·5 mm. diameter drop in wax at 580 ft./sec.

Figs. 4 and 5 show how the air preceding the projectile blows the web away, leaving a roughly spherical drop to be struck by the projectile. Fig. 4 shows the drop suspended on the web and Fig. 5 the web being blown away. The projectile speed in this instance was 770 ft./sec.

Apart from the study of impressions of water drops on various surfaces other liquids can be tried; small drops of mercury have been successfully used. Another development proposed is to fit a piezoelectric crystal in the nose of the projectile to study impact forces and pressures. It may also be possible to study the effect of shock waves on water droplets and to investigate further the droplet break-up processes at very high speeds if the apparatus can be developed to give transonic speeds.

Acknowledgment is made to the Chief Scientist, Ministry of Supply, with whose permission this communication has been written, and to Mr. W. C. Clothier and Mr. D. G. A. Rendel for the help and encouragement given in this work.

## A Fluctuating Celestial Radio Source at 242 Megacycles per Second

DURING our recent radio mapping survey at 242 Mc./sec. of the region near the antigalactic centre, we have detected a fluctuating radio source. The fluctuations appear similar to the scintillations observed at lower frequencies as caused by the ionosphere[1]. No scintillation or fluctuation effect had been observed by us on any source in all our previous observing at or near 242 Mc./sec. Accordingly, this source was regarded with great interest, since it appeared likely that scintillations at this frequency and at a high altitude (about 60°) might mean that the source was of very small angular extent, or at least smaller than the sources having scintillation at lower frequencies and smaller than any other source we have detected. In other words, the source may be of stellar dimensions, that is, a true radio star. Although the fluctuations may be due to scintillations, there is also evidence that the fluctuations may represent variations in the intensity of the source itself.

Since the phenomenon may be caused by either scintillations (of ionospheric or tropospheric origin) or by true variations in intensity of the source, or both, the term 'fluctuation' will be used to describe the effect, whatever its cause. The first fluctuation record of the object was obtained on January 22, 1955. A photograph of this record is shown by the upper trace in Fig. 1. It is to be noted that the peaks of the fluctuations clearly outline the envelope of the antenna pattern. The source was again detected as a slight rise but without the marked fluctuation effect on January 23, 1955. A photograph of thi record is shown by the lower trace in Fig. 1. Th large deflexions appearing on the records at 1.00 a.m are calibrations impressed automatically once eacl hour. The marks extending below the traces a 10-min. intervals are time marks impressed auto matically from *WWV* time signals at the beginnin of each 600 c./s. tone interval. The horizonta co-ordinate is right ascension ($\alpha$) (1950.0).

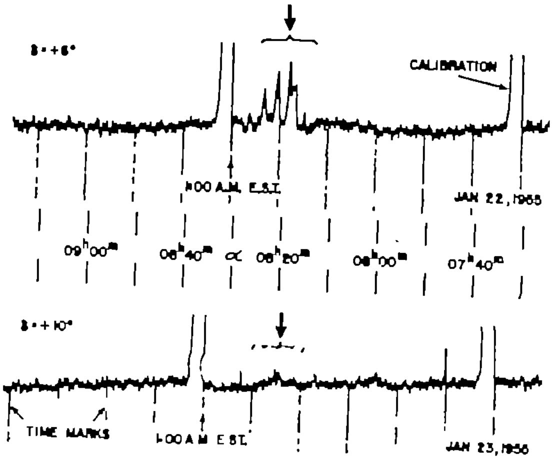

Fig. 1. Signatures obtained with the 96-helix Ohio State University radio telescope in which a source with marked fluctuations appears on January 22, 1955, but on the next night as a slight rise. The position of the source is indicated by the heavy arrows. The antenna has a fan beam 1·8° wide in right ascension by 8° in declination

Our observations of the source were interrupted afte January 23 by a routine survey, but during April anc May of this year the source has been re-observed. A total of fourteen good records of the source have now been obtained with the following results: on January 22, April 17, April 30 and May 11, 1955, the source shows marked fluctuations, whereas on December 9, 1954, January 23, April 14, 15, 16, 20, 27, and May 9, 10 and 15, 1955, the source shows only as a slight rise.

Without the fluctuations the source has an intensity of about $1 \times 10^{-26}$ W. m.$^{-2}$ (c./s.)$^{-1}$. With fluctuations the intensity increases for short periods by a factor of 6 or so. The marked fluctuations have a period of 2–3 min.

Owing to the weakness of the source and its fluctuating nature, it is difficult to determine its position accurately. Our present best position (1950.0) is: R.A. 08h. 19m. ± 1m.; Dec. +8° ±3°. This is close to the source reported in our list of 207 sources[2] as Hydra *P*.

It was mentioned that there are some factors in favour of the interpretation that the fluctuations are intrinsic variations in the source and not scintillations. These are: (1) marked fluctuations have been observed near midnight and also near sunset; this result cannot be correlated with the usual diurnal variation observed in scintillations; (2) marked fluctuations have never been observed on two consecutive days, or in fact at a more frequent interval than 11 days; (3) it has not been possible to establish any correlation between the marked fluctuations and any solar or ionospheric phenomena; (4) very occasionally, large peaks in intensity are observed that resemble solar bursts.

If the fluctuations are intrinsic variations in the source, an explanation is that the source is a star th variable radio emission having a period of hours days and also a short period of a few minutes. course, the fluctuations may be due to both ntillations and variability, in which case the short-riod fluctuations may be true scintillations that observed only when the source is at or near ximum intensity and the ionospheric conditions also suitable.

Whatever the explanation, the observations suggest at the source may be a true star or a new class of lio object. Attempts to identify the source with optical object have not yet been successful. More servations are needed to improve the accuracy of position and to follow the fluctuation periods. fortunately, this source is observable now only ring the day at times at which severe radio interence is encountered on most days. Accordingly, re detailed observations may have to wait until source is again in a favourable observing position.

## Liquid Immiscibility in a Silicate Melt

The formation of immiscible liquids in silicate elts has been suggested as one of the possible ethods by which natural magmas may produce a riety of rock types. This theory has, however, t found much favour among petrologists, because the lack of observational and experimental idence. Bowen[1] pointed out that direct evidence this phenomenon, if it existed in rock melts, should found in glassy lavas such as obsidian; in these vas would be found discrete spheres of one glass ibedded in another glass of different composition. such phenomena have been observed. Greig[2] nducted extensive laboratory investigations on miscibility in binary and ternary silicate systems. ie areas of liquid immiscibility which he found lay ll away from those representing even abnormal ok compositions. More recently, however, Roedder[3] und an extensive region of low-temperature miscibility in the system $FeO—K_2O—Al_2O_3—SiO_2$. is new region of immiscibility fell much closer to e compositions of some abnormal rock types. rect evidence of the existence of silicate immiscibility in Nature has still been lacking, however.

In a recent study of tektites directed towards a eory of their origin, we considered the possibility at the so-called 'lechatelierite' inclusions frequently ported in these glassy bodies might really represent uid immiscibility. This idea is not original; it has en put forward, but for various reasons discarded, Barnes[4].

A series of experiments using the quenching ethod was carried out on an artificial mixture of da, lime, magnesia, alumina and silica approximating in composition to an iron-free tektite. Certain quenched charges consisted of small spheres of e glass embedded in much larger quantities of a second glass, thus giving evidence of immiscibility in the liquid state. This prompted a further test on actual tektite material sealed in a platinum envelope in a small evacuated silica tube to prevent oxidation of the ferrous iron. The quenched sample again showed the same phenomenon—small spheres of glass embedded in the greater mass of glass of slightly higher refractive index. The phase represented by the spheres made up something less than one per cent of the whole.

From this evidence we conclude that the so-called 'lechatelierite' inclusions in tektites most probably represent a state of liquid immiscibility in a silicate melt. It appears to be the only evidence of this phenomenon yet found in Nature.

## Observations of Spiral Growth Steps in Ethylene Polymer

The role of dislocations in crystal growth has been discussed by N. F. Mott[1], and later, evidence was given by Griffin[2] to support the mechanism suggested by Frank[3]. Since that time there has been striking examples of this type of growth, described by Dawson and Vand[4], and Forty[5] along with Verma[6], to mention a few.

No report, however, seems to have appeared indicating that growth by a dislocation mechanism can take place in a polymer. All evidence of crystallization of polymers seems to be of a different character.

Recently, growth by a dislocation mechanism has been observed in 'Marlex 20*' (trade name of Phillips Petroleum Co.), a predominantly polymethylene structure with limited branching along the polymer chain. Preliminary work indicates the distribution of molecular weights to be approximately linear from 2,000 to 28,000, with a mean molecular weight of 10,000. These small crystals were grown from hot solution in xylene, were shadow cast[7] (∢ 2 : 1) and examined

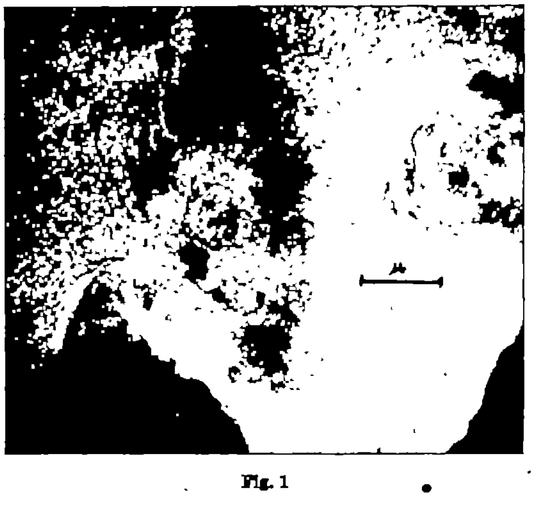

Fig. 1

in the electron microscope. Spiral growth was evident in numerous specimens obtained from both hot xylene and benzene solutions. Fig. 1 illustrates one of the simplest examples of this growth, showing growth from a single spiral. Generally, more complicated effects are observed due to the impingement of growth layers. In larger aggregates, the lozenge shape seems to persist.

I wish to thank the Phillips Petroleum Co. for their specimen.

## Reduction in X-ray Sensitivity of Seeds by Hydration

Numerous investigators have reported that when seeds are soaked there is a parallel increase in their water content and sensitivity to X-rays[1]. These studies have been taken as strong support for the postulate that much radiation injury results 'indirectly' from the decomposition and/or ionization of water. Therefore, it was of some concern to us when it was shown there was actually an inverse relationship between the water content of dormant barley seeds and their sensitivity to X-rays[2]. For this reason it seemed desirable to re-investigate the relation between radiosensitivity and the water content of soaked seeds.

Dormant seeds, originally stored over phosphorus pentoxide until they reached weight equilibrium, were soaked at 0° C. and 22° C. for different periods of time and then subjected to X-rays. They were grown for seven days and the average heights of the seedlings compared with those of irradiated unsoaked seeds (Fig. 1).

From these results it is clear that the sensitivity of seeds to X-rays decreases after one hour of soaking at 22° C. However, after four hours soaking they are about as sensitive as dry controls. In contrast to this, when soaked at 0° C. the seeds slowly increase in resistance to X-rays, so that after four hours tl reach a point of maximum resistance comparable that obtained after one hour soaking at 22° C. Tl maintain this level of tolerance when the soak period is extended up to eight hours. Howev further soaking results in a gradual increase sensitivity and after 24 hr. they are about as sensit to X-rays as the dry control. It is significant tl the embryo rapidly absorbs water, and the wa content of embryos of seeds soaked at both te peratures for one hour equals about 40 per cent their wet weight. After 24 hr. soaking it only creased to about 60 per cent. The correspondi water content of the embryo of the dry control w 4 per cent.

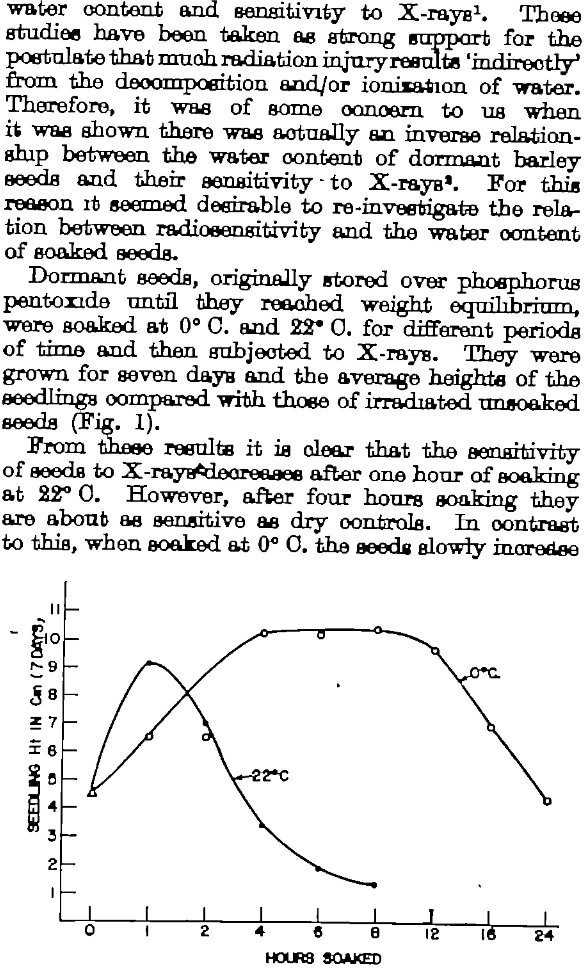

Fig. 1. Effects of soaking barley seeds at 22° C. and 0° C. on their sensitivity to 15,000 r. of X-rays

Two points seem clear from this work: (1) t X-ray sensitivity of dry seeds can actually be creased by periods of soaking at both 0° C. and 22° ( (2) the duration of the reduced sensitivity is related the temperature of the steeping water and is probal associated with increased physiological activity.

These results suggest that the radio-decompositi of water may play a less significant part in modifyi radiosensitivity than has previously been assign to it.

## Distribution of Radiocarbon in Tobacco Mosaic Virus

We have made radioactive tobacco mosaic vir by exposing leaves from infected tobacco plants radioactive carbon dioxide for one day in ligh treating the homogenized leaves with buffer solutio and purifying the virus by repeated precipitation the isoelectric point[1]. The virus is determined b colour reaction, burned, and the radioactivity of tl resulting carbon dioxide measured with a gas Geig counter[2]. It has been found that the specific radi activity (activity per unit weight) of the virus decrease with increasing 'age', that is, with increasing tim interval between infection and radiophotosynthesi up to an age of about four weeks[3,4]. In addition, or sample of tobacco mosaic virus, aged two month was analysed for distribution of radioactivity. Tl nucleic acid was split off by treatment with trichlor acetic acid[5], and the protein hydrolysed and divide into the individual amino-acids by column chromat graphy[6]. A large part of the radiocarbon was foun in the nucleic acid, and the distribution of the radi carbon among the individual amino-acids was qui uneven[7].

Using the methods described, we have no determined the distribution of the radiocarbo between nucleic acid and protein as a function age of the virus. The samples of tobacco mosaic vir were the same as those used in the previous work The seeds had been sown in March, the plants tran ferred to the open field in May, and infected (fir series; *A*) early in July, or (second series; *B*) la

August. For the purpose of Tables 1 and 2, all sults have been combined, as no significant differ-oes between the two series appeared. The sample arks in the first vertical column of Table 1 establish e connexion with the previous paper, where further ta on the samples are found[4]. The activity values ted in Table 1 are the actual numbers of disintegra-ns per minute. Where the sum of the activities the protein and the nucleic acid (columns 4 and 5) es not fully agree with the activity of the tobacco saic virus, as measured independently (column 3), e percentages are referred to the sum. For clarity, ean values of the percentages are given in Table 2.

ble 1. ACTIVITIES OF TOBACCO MOSAIC VIRUS PROTEIN AND NUCLEIC ACID

| Sample | Age (weeks) | Activities (disintegrations/min.) | | |
|---|---|---|---|---|
| | | Tobacco mosaic virus | Protein component | Nucleic acid component |
| *A* 1 | 1 | 2,050 | 400 (20 per cent) | 1,650 (80 per cent) |
| *A* 2 | 1 | 2,900 | 300 (14 ,, ) | 1,850 (86 ,, ) |
| *A* 4 | 2 | 13,800 | 5,550 (37 ,, ) | 9,550 (63 ,, ) |
| *B* 1 | 2 | 1,950 | 500 (25 ,, ) | 1,550 (75 ,, ) |
| *B* 2 | 2 | 9,400 | 3,600 (42 ,, ) | 5,050 (58 ,, ) |
| *A* 5 | 3 | 3,700 | 2,200 (60 ,, ) | 1,500 (40 ,, ) |
| *B* 3 | 3 | 2,900 | 1,850 (55 ,, ) | 1,550 (45 ,, ) |
| *B* 4 | 3 | 8,800 | 5,100 (65 ,, ) | 2,750 (35 ,, ) |
| *A* 7 | 4 | 3,850 | 1,600 (39 ,, ) | 2,450 (61 ,, ) |
| *B* 8 | 5 | 59,500 | 17,000 (32 ,, ) | 35,200 (68 ,, ) |
| *A* 11 | 6 | 7,700 | 4,650 (69 ,, ) | 2,100 (31 ,, ) |
| *A* 12 | 6 | 2,950 | 1,400 (48 ,, ) | 1,500 (52 ,, ) |
| *A* 13 | 9 | 15,600 | 9,150 (65 ,, ) | 4,950 (35 ,, ) |
| *A* 21 | 11 | 34,600 | 24,000 (66 ,, ) | 12,100 (34 ,, ) |
| *A* 22 | 11 | 24,700 | 15,700 (65 ,, ) | 8,550 (35 ,, ) |

Table 2. MEAN VALUES

| Age (weeks) | Per cent activity in | |
|---|---|---|
| | Protein | Nucleic acid |
| 1 | 17 | 83 |
| 2 | 35 | 65 |
| 3–4 | 55 | 45 |
| 5–6 | 50 | 50 |
| 9–11 | 65 | 35 |

In spite of the large fluctuations of individual lues (Table 1) it is clear from Table 2 that, in neral, the fractional radiocarbon content of protein creases greatly with age of the virus. Thus young rus, which is still growing rapidly, directs radio-rbon (that is, carbon newly introduced into the af) relatively more efficiently into the nucleic acid an does old virus.

Tobacco mosaic virus contains 50 per cent carbon; t its nucleic acid (5·6 per cent of the weight of rus) has 36 per cent carbon only[6]. Hence the antity of carbon in the protein is 24 times greater an that in the nucleic acid. Applying this figure the data of Table 2, one finds that in tobacco saic virus one week old the specific activity of e nucleic acid carbon is about 115 times larger than at of the protein carbon, but in virus about ten eks old only 13 times larger.

# Inhibition by Cyanide of the Photochemical Activity of Isolated Chloroplasts

CYANIDE is an effective inhibitor of the photosynthesis of most plants. Photosynthesis in weak light is relatively insensitive to cyanide, whereas studies with flashing light show that cyanide does not affect the yield of oxygen from each light flash if the dark time between flashes is made long enough. Experiments of this type, together with other lines of evidence, all indicate that the cyanide-sensitive phase of photosynthesis is the primary reaction in the fixation of carbon dioxide[1]. It should not be concluded, however, that all the other reactions in photosynthesis are insensitive to cyanide. The apparent lack of sensitivity of other reactions may result simply from a low concentration of the carboxylating enzyme system relative to other enzymes. Under such conditions, cyanide would appear to be selective for the carbon dioxide fixation process[1].

It was not possible to examine directly the effect of cyanide on any of the other reactions of photosynthesis until the discovery by R. Hill[2] that isolated chloroplasts could split water with the formation of hydrogen ions and oxygen gas upon illumination in the presence of a suitable electron acceptor (oxidant). This reaction (the Hill reaction) is generally regarded as representing the oxygen-evolution part of photosynthesis. The Hill reaction, in confirmation of the picture based on studies of photosynthesis, has been reported to be insensitive to cyanide[3], although Macdowall[4] observed 15–20 per cent inhibition with 0·01 *M* potassium cyanide. Recent

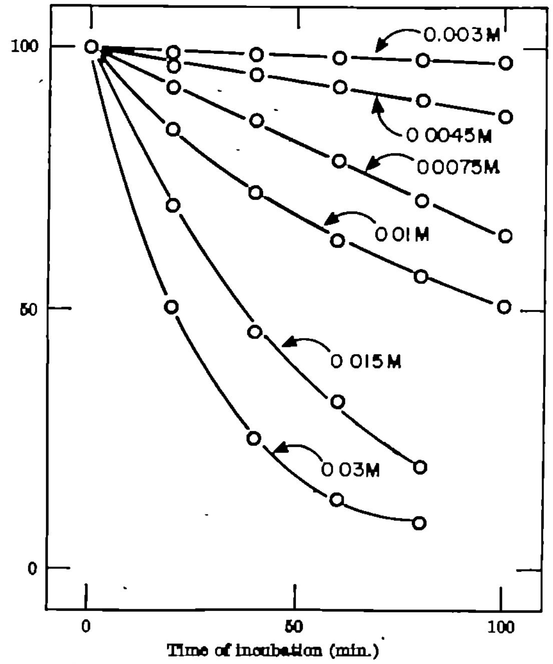

Fig. 1. Progressive inhibition of the Hill reaction by potassium cyanide. Rates are relative to uninhibited controls. Isolated chloroplast fragments were incubated with cyanide in sealed tubes at 2° C. and Hill reaction activities were measured potentiometrically (ref. 5) at the times shown at 10° C., with 0 0005 *M* potassium ferricyanide as the oxidant

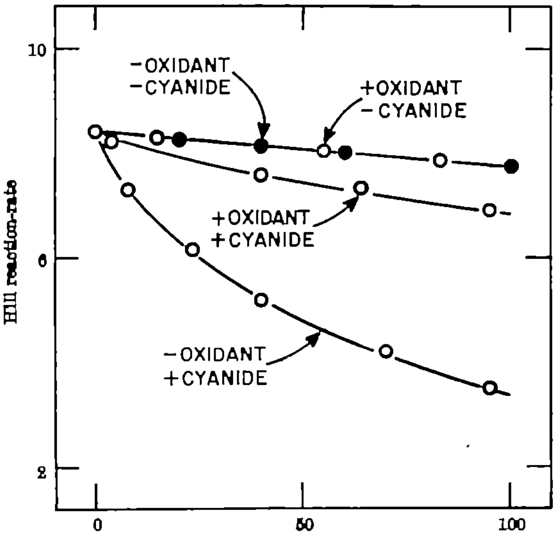

Fig. 2. Effect of oxidant (0·0015 *M* potassium ferricyanide) on the inhibition of the Hill reaction by 0·01 *M* potassium cyanide. General reaction conditions were the same as in Fig. 1. Rates are expressed as m.moles ferricyanide reduced/hr./mgm. chlorophyll

work in this laboratory, however, indicates that the Hill reaction is more sensitive to cyanide than has been previously reported if examined under certain conditions.

Chloroplast fragments from rhubarb chard and sugar beet (*Beta vulgaris*), prepared and stored in a potassium chloride – sucrose medium as previously described[5], were incubated at 2° C. in sealed tubes at *p*H 6·8 in the presence of different concentrations of potassium cyanide. At intervals, 1-ml. samples were removed and the Hill reaction activity was measured at 10° C. by a potentiometric method[6]. Similar results were obtained with the usual manometric technique. The results from a typical experiment of this type are given in Fig. 1. As the curves show, cyanide is a rather effective inhibitor. It demonstrates a very definite progressive effect, however, in that the degree of inhibition increases with time. Maximum inhibition is attained only after prolonged contact with the chloroplast fragments.

These results were contrary to earlier studies made in this laboratory using a standard technique in which the oxidant and the inhibitor (cyanide) were mixed before the chloroplasts were added. Under these conditions, cyanide produced only slight inhibition even at concentrations greater than 0·01 *M*. This indicated that the oxidant had some effect on the inhibitory action of the cyanide. Cyanide inhibition was then studied with and without the presence of oxidant during the incubation period. The results of a typical experiment of this type are given in Fig. 2. The curves clearly show that no appreciable inhibition by cyanide develops in the presence of the oxidant. These observations, together with the progressive time-effect described above, might very well account for the lack of inhibition of the Hill reaction by cyanide reported by other workers.

The mechanism by which cyanide inhibits the Hil reaction activity of chloroplast fragments is no known. Experiments now in progress indicate tha both the light and the dark rate-limiting processes are affected by cyanide. However, the light-reactio appears to be considerably more sensitive than th dark-reaction. It should be pointed out that th apparent cyanide inhibition described above could b interpreted in terms of an acceleration of the chloroplast inactivation reactions by the cyanide.

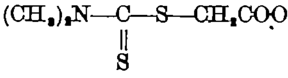
## A New Type of Plant Growth-regulating Substances

IN the course of systematic investigations of th dithiocarbamates, the compound S-(carboxymethyl) dimethyldithiocarbamate,



$$(CH_3)_2N—\underset{\displaystyle S}{\overset{}{\underset{\|}{C}}}—S—CH_2COOH$$

(I)

obtained by the reaction of sodium dimethyldithio carbamate with monochloroacetic acid, was found t exhibit distinct plant growth-regulating activity Tomato plants, about 20 cm. high, from which th tip was replaced by a glass tube containing a 1,00 p.p.m. solution of this compound showed very clea epinastic curvature and leaf deformations (Fig. 1

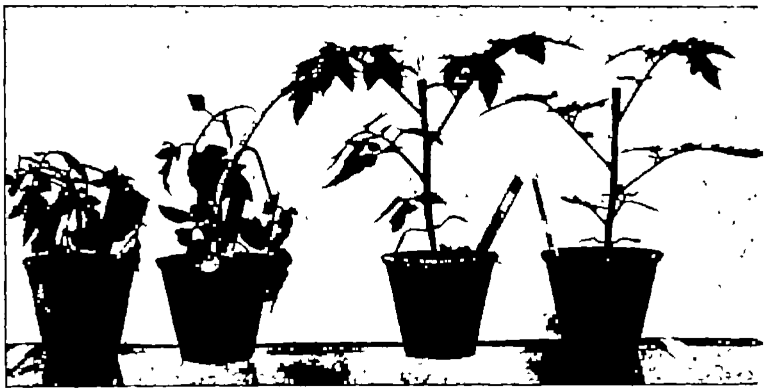


Fig. 1. *Left:* Two tomato plants the stem tips of which have been replaced by a glass tube containing a 1,000 p.p.m. solution of S-(carboxymethyl)-dimethyldithiocarbamate (compound I). Photographed after one day.

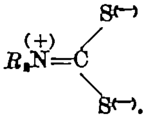
*Right:* Two tomato plants which were treated in the same way with water ich were of the same type as those caused by -dichlorophenoxyacetic acid.

Growth responses, especially curvatures, and ght deformations of leaves resembling those ought about by synthetic growth substances were o found after application of the compound to cumber and pea plants. When applied to the soil potted plants a similar picture was obtained, licating a translocation of the active substance thin the plants. Activity could also be shown on ot initiation of tomato and *Phaseolus*.

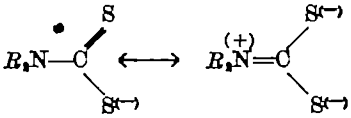
In the Went pea test, the compound had an tivity of 1 per cent, in the *Avena* cylinder test and o in the sunflower stem test[1] the activity was about er cent of that of indole-3-acetic acid. Its activity the classical *Avena* curvature test was very weak.

These observations seem to conflict with the first the now generally recognized structural requirements for plant growth-regulating activity, namely, e presence in an active compound of a basal ring stem with high surface activity (cf. ref. 2).

Some years ago, when investigating the relation tween chemical structure and antifungal activity the series of the dialkyl dithiocarbamates[3], arguments were brought forward for the view that the gh and specific antifungal activity of the lower alkyldithiocarbamates depends on the occurrence the chemical structure

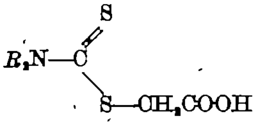


was assumed that this structure can only be rmed if in the system



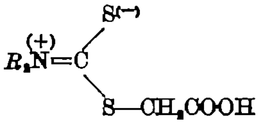
e nitrogen atom in the dialkyldithiocarbamate ion aided in its mesomeric electron release to the  group. This aiding effect is maximal for e methyl group and quickly diminishes if $R$ is placed by higher alkyl groups. Thus, what happens that the N—C bond in the dialkyldithiocarbamate n acquires a certain amount of double-bond charter under the influence of electron-releasing subituents $R$.

Returning to the plant growth-regulating prorties of compound I, it is tempting to suggest that tivity in the series



(II)

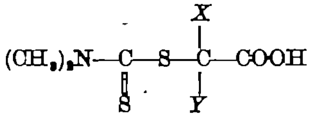
again connected with the possibility that the N—C nd acquires a double-bond character as a conquence of similar internal electron shifts :



In this way a 'ring' system bearing a polar side-chain in a distinct spatial position as required for growth-regulating activity is formed.

In view of the earlier work outlined above, it might be expected that replacement of $R$ = methyl in compound (II) by higher alkyl groups would quickly lead to compounds without plant growth-regulating activity. In fact it was found that already S-(carboxymethyl)-diethyldithiocarbamate ($R = C_2H_5$) is much less active.

In connexion with the observations of Wain[4] regarding the influence of side-chain substitution on growth-regulating activity in the series of the aryloxyalkylcarboxylic acids, the effect of replacement by alkyl groups of one or both hydrogen atoms in the $CH_2$-group of compound I was investigated. In accordance with his results, it was found that growth-regulating activity in the series



$$(CH_3)_2N-\underset{\underset{S}{\|}}{C}-S-\overset{\overset{X}{|}}{\underset{\underset{Y}{|}}{C}}-COOH$$

is observed only if at least one of the substituting groups $X$ and $Y$ is hydrogen. Further, it has been observed that replacement of C=S in compound I by C=O results in loss of growth-regulating activity. Activity is maintained, however, if the sulphur atom in the group C—S—C is replaced by oxygen.

Table 1 summarizes our observations on the growth-regulating properties of the dithiocarbamate derivatives under consideration.

Table 1. PLANT GROWTH-REGULATING PROPERTIES OF A NUMBER OF DITHIOCARBAMATE DERIVATIVES

|  $(R_1)_2N-\underset{\underset{S}{\|}}{C}-S-\overset{\overset{R_2}{|}}{\underset{\underset{R_3}{|}}{C}}-COOH$ | Results obtained in the tomato leaf epinasty test, the Went pea test, the *Avena* cylinder test and in the sunflower stem test |
|---|---|
| $R_1 = CH_3$ $R_2 = R_3 = H$ | Active |
| $R_1 = C_2H_5$ or higher alkyl groups $R_2 = R_3 = H$ | Slightly active or inactive |
| $R_1 = CH_3$ $R_2 = CH_3$ $R_3 = H$ | Active |
| $R_1 = CH_3$ $R_2 = C_2H_5$ $R_3 = H$ | Active |
| $R_1 = CH_3$ $R_2 = R_3 = CH_3$ | Inactive |
|  $(CH_3)_2N-\underset{\underset{O}{\|}}{C}-S-CH_2COOH$ | Slightly active or inactive |
|  $(CH_3)_2N-\underset{\underset{S}{\|}}{C}-O-CH_2COOH$ | Active |

With regard to the side-chain bearing the polar group, the compounds listed follow the activity pattern already known for other synthetic growth-regulating substances. The interesting new feature observed with these compounds seems to be that the electron shifts caused by simple substitutions in the remaining part of the molecule may, or may not, lead to the specific spatial arrangements required for growth-regulating activity.

The activity of the ethyl esters followed the same line as that of the corresponding free acids.

A fuller account of this work will be published elsewhere.

We are indebted to C. W. Pluygers for synthesizing the chemical compounds, and to G. Meyer for carrying out a number of biological tests.

## Basophilia and High Ribonucleic Acid Content of Dividing *E. coli* Cells

IN a previous communication[1], a staining technique was described for demonstrating the wide difference in basophilia of growing and non-growing cells of *E. coli*. The high basophilia of growing *E. coli* cells has been attributed by Belozersky[2] to the presence of pentose nucleic acid which is not attached to protein. Apart from the work of Belozersky and his collaborators, the nature of the additional ribonucleic acid has received little attention, although it has been known for some years that rapidly growing and dividing cells of bacteria have a substantially higher concentration of ribonucleic acid than resting cells, and there is ample evidence of the heterogeneity of ribonucleic acid in metazoan cells[3].

To characterize the additional ribonucleic acid in dividing cells of *E. coli* (N.C.T.C. No. 1100) and to determine whether or not it reflects a general increase in the existing complement of constituents containing ribonucleic acid of the cell, the ribonucleic acid of rapidly dividing cells and resting cells of this bacterium were subjected to various fractionations. Dividing cells were obtained from a casein/casein/yeast culture[4] during the phase of maximum growth and of rate of division; resting cells were obtained from a fully grown culture.

When disintegrates of these cells were fractionated by centrifugation, it was found that the basophilia of dividing cells was located in the deposit obtained between 25,000 *g* and 100,000 *g*. Chemical analyses revealed that the ribonucleic acid in this fraction exceeded that in the corresponding fraction from resting cells by the difference in the total ribonucleic acid concentration of the unfractionated dividing and resting cells. The coincidence of the additional ribonucleic acid and the basophilia in one fraction lends support to Belozersky's contention that ribonucleic acid is responsible for the high basophilia of these cells. However, the possible heterogeneity of this fraction has not been investigated, and it is not known whether the ribonucleic acid responsible is attached to protein or not. The ribonucleic acid content of the basophilic fraction was approximately 40 per cent ribonucleic acid nitrogen/total nitrog
This figure was calculated from a determination
the acid-insoluble pentose as determined by Militz
and the ribonucleotide ratio of the whole ribonucl
acid of the cell.

The finding of basophilic and ribonucleic acid-r
particles in dividing bacterial cells is of particu
interest in view of the discovery by Petermann *et al*
of similar submicroscopic particles in chick embr
regenerating liver and tumours which they detec
in the analytical centrifuge at 95,000 *g* and beli
to be rich in ribonucleic acid. In regenerating liv
Petermann[6] was able to correlate the high concent
tion of these particles with rapid cell division.

The identification of the ribonucleic acid-r
particles from dividing *E. coli* cells with those fr
dividing metazoan cells would support the suggest
made previously[8] that the additional ribonucleic a
of dividing and growing *E. coli* cells is more direc
concerned in the division process than the grow
process.

## Anaerobic Metabolism of Thiocyanate by Thiobacilli

IN 1904, Beijerinck[1] first described the decom
position of ammonium thiocyanate by Thiobacil
Thirty-three years later, Happold and Key[2] report
the disappearance of thiocyanate from gas liquo
due to microbial activity. The thiocyanate-oxidizi
organism was only obtained in pure culture
Happold, Johnstone and Rogers[3] in 1952. In
subsequent publication, Happold, Johnstone, Rog
and Youatt[4] characterized the organism finally as
strict autotroph which aerobically oxidized thi
cyanate to sulphate, carbon dioxide and ammon
The organism grew with carbon dioxide as sole sou
of carbon, and could derive its energy from the oxid
tion of sulphur and thiosulphate with oxygen
oxidant. The name *Thiobacillus thiocyanoxidans* w
suggested.

The oxidation of thiocyanate by Thiobacilli und
anaerobic conditions with nitrate as oxidant was d
covered in this laboratory some months ago. It w
found that certain strains of *Thiobacillus denitrifica*
isolated from surface water and from corroded sew
concrete were capable of oxidizing thiocyanate wi
the production of gaseous nitrogen. Strains *A*3-1 a
VIb-1, two of six pure cultures examined, wh

tivated in a medium containing 0·1 per cent monium thiocyanate, 0·05 per cent ammonium oride, 0·02 per cent potassium dihydrogen phos-ate, 0·1 per cent sodium bicarbonate, 0·1 per cent assium nitrate (*p*H 7) in Struyk tubes, invariably duced gas within a period of two to three eks.

Enrichments with surface water containing 0·1 per it ammonium thiocyanate, 0·1 per cent potassium rate, 0·05 per cent ammonium chloride and per cent sodium bicarbonate similarly showed itrification with the disappearance of thiocyanate. s production was, however, much slower than in responding enrichments containing thiosulphate. e adaptation of other Thiobacilli to thiocyanate s also studied. Two locally isolated pure cultures *Thiobacillus thioparus* grew well in an autotrophic dium containing 0·05 per cent sodium thiosulphate i 0·05 per cent thiocyanate. In a medium conning 0·05 per cent ammonium thiocyanate as sole idizable source of sulphur, no macroscopically ible growth occurred, however, although the cells nained viable.

Further study of this subject is in progress and l be published elsewhere. This communication is blished by permission of the South African Council Scientific and Industrial Research.

## Deoxyribonucleic Acid Content of the Nucleus and Nuclear Volume

T seems of interest to analyse if, in a given species, re is any relationship between the volume of the -nuclei and their deoxyribonucleic acid (DNA)-tent. Except within the same tissue, H. H. Swift[1] ies the existence of such a relationship. Recent lings by G. Marinone[2] in cells of different nature hæmatopoietic organs are in agreement with this view. C. Leuchtenberger and F. Schrader[3], however, conclude that even in the same organ—the liver of the white rat—no direct relationship exists between the nuclear volume and the DNA-content.

We have now undertaken the determination, by the histophotometric technique of L. Lison[4], of the DNA-content of the liver-cells in the white rat under different experimental conditions, to re-investigate the problem of the DNA-content/volume relationship within this tissue. The nuclei of the three classes (***2n***, ***4n***, ***8n***), of which the average DNA-content increases following a geometrical progression 2 : 4 : 8 (the average DNA-content of the lowest class (***2n***) doubling nearly that of the spermatozoa) were separated. In each of these classes the volumes of the spherical nuclei were easily calculated from their circular projection area. The average nuclear volumes for the three given classes follow exactly the same progression as the average DNA-content. Statistical computations of the results obtained in the liver of five normal rats, fixed (in alcohol 20 parts, formalin 15 parts, acetic acid 5 parts), embedded and stained by the Feulgen-reaction under the same conditions, are summarized in Table 1. It is shown that between the 'DNA-content-classes', ***2n*** and ***4n***, not only the average DNA-content but also the average nuclear volume doubles. The 1 : 2 ratio becomes more precise with an increasing number of measurements (pooled results).

The scarceness of the nuclei of the ***8n*** class (2–4 nuclei for 250 measurements) makes a statistical analysis difficult. However, it is evident that the volumes of those nuclei are ranged about the double of the average volume of the ***4n*** class. From those results one could conclude that the 'DNA-content-classes' coincide with the 'nuclear-volume-classes'.

Within one of those classes the relationship between the DNA-content and the volume is not so evident for the different individual nuclei. From correlation diagrams obtained for the five livers studied, which we shall more extensively describe in another paper, one gets, however, the impression that such a relationship exists, at least to a certain extent. Although varying largely for each DNA-content value, the volume seems to present a mean value increasing with the DNA-content.

One might speculate that in the case of the rat liver the coinciding 2 : 4 : 8 ratios between the average volumes and between the average DNA-contents of the three nuclear classes depend on a common reduplicating factor (possibly polyploidy or polyteny), and within one class the DNA-content could be at least one factor acting upon the volume of individual

## Growth-promoting Activity for Pigs of Inactivated Penicillin

It has been shown by many workers that the regular administration of very small doses of most antibiotics, including penicillin, will significantly increase the rate of growth of many species of animals. Extensive investigation, however, has not clearly demonstrated the mechanism or mechanisms by which such a benefit is derived, although it is generally considered that the mode or modes of action are entirely dependent upon the antibacterial activity of the antibiotic employed[1]. It has been suggested, however, that autoclaved penicillin when given by daily injection, but not by mouth, will increase the growth-rate of chicks[2].

The results of two experiments reported here show that part of the benefit derived from a supplement of penicillin is due to one or more of its degradation products, probably the amino-acid penicillamine, and that inactivated penicillin, showing no antibacterial activity whatever, significantly increased the growth-rate of pigs, when given either by mouth or by injection.

The first experiment involved five groups of pigs, each group containing eight animals, which were maintained from weaning to 200 lb. live-weight. Procaine penicillin *G* was added to the diet at the rate of 15 gm. per ton of food, and groups receiving penicillin which had been inactivated by heat, by the action of penicillinase and by contact with heavy metals, were compared with a group receiving active penicillin, and a control group receiving no penicillin. It can be seen from Table 1 that each group receiving inactivated penicillin showed an increase in growth-rate and a reduction in food conversion ratio.

Table 1

| Antibiotic | State | Growth-rate (lb /day) | Increase over control (per cent) | Food conversion ratio | Food saved (per cent) |

| Penicillin | Active | Parenteral | 1·19 | 11·2 | 3·65 | 9 |
| Penicillin | Inactive | Parenteral | 1·13 | 5·6 | 3·67 | 8 |

Table 3

| Experiment | Growth-rate (lb./day) | | | Food conversion ra | | |
|---|---|---|---|---|---|---|
| | Control | Active | Inactive | Control | Active | In-acti |
| 1 | 1·14 | 1·25 | 1 21 | 3·81 | 3·56 | 3·7 |
| 2 (first replicate | 0·88 | 1·08 | 1 01 | 3·19 | 2·92 | 3 0 |
| 2 (second replicate) | 1·04 | 1·20 | 1·15 | 4·11 | 3·61 | 3·6 |
| Mean increase over controls | — | 14·3 per cent | 9·4 per cent | — | 9·2 per cent (food saved) | 5·5 pe cent (food save |
| Significance (deviation from controls) | | $p<0.01$ | $p<0.05$ | | | |

The second experiment compared active and inactive penicillin when given by mouth and by injection. The experiment was replicated twice and involved 120 pigs. The animals were maintained
the experiment from weaning until they reac
120 lb. live-weight and were fed a recommen
ration[3]. Procaine penicillin was inactivated w
penicillinase and was administered at the rate
15 gm. per ton of food, or 0·5 mgm. per kilo bo
weight daily by intramuscular injection. Both rou
of administration supplied approximately the sa
total daily intake of antibiotics. It can be seen fr
Table 2 that in every case the inactive mate
produced an increase in growth-rate and a reduct
in food conversion ratio, irrespective of the route
administration. In a comparable experiment,
activated aureomycin hydrochloride was found
produce no growth response.

The results of both experiments are summari
in Table 3. Active penicillin produced a signific
mean increase in growth-rate of 14·3 per cent,
inactive material produced a significant mean incre
in growth-rate of 9·4 per cent. The inactive mate
thus produced 66 per cent of the growth respo
achieved with active penicillin. The difference
tween the effect of the active and inactive mate
was not significant.

The inactive material showed no activity *in v*
against a range of test organisms, and no penic
could be detected in the digestive tract, serum
urine of animals receiving the inactivated mater
It seems likely that the only relatively stable e
product common to each of the three methods
inactivation employed is the thiol amino-acid pe

llamine (E. L. Smith, personal communication), hich has already been shown to be capable of creasing the growth-rate of chicks when given by aily injection[4]. Further work is being undertaken sewhere to evaluate the nutritional significance of is material.

We are grateful to Dr. R. C. Campbell for statistical nalysis of the experimental results, to Mr. R. Long Glaxo Laboratories, Ltd., for preparation of the activated penicillin, and to Glaxo Laboratories, td., for supplying the penicillin used in these periments.

## A New Rare Blood-Group Antigen, $Chr^a$

During recent years, many rare blood-group ntigens, so-called 'private' or 'family' antigens, have een discovered. A survey of eleven of these was ecently made by van Loghem and his associates, ho described two new antigens. Most of the antiens were found exclusively in the members of one amily; but as suggested by Dunsford, who studied he Wright system, some of these antigens may be rdinary blood-group factors with a very low freuency. Most of the corresponding antibodies were he results of iso-immunization during pregnancy or y blood transfusion, but a few of them were naturally ccurring antibodies.

Through routine screening for blood-group antiodies we found a hitherto unknown antibody, which t 37° C. agglutinated trypsinized red cells from one of he test-cell donors, who happened to be the present riter. The serum donor was a nineteen-year-old nmarried woman, who had never received transsions and had never been pregnant. Serological vestigations showed that the antibody was most ctive in albumin at 37° (titre 8). It was less active saline and by the trypsin technique, and it gave o reaction by the indirect Coombs technique. he antibody was weakly active at 20°. The test rum has since been tested against the red cells om 311 persons selected at random; but so far has been found to react with the red cells from nly one more person.

Investigations of the blood-group genotypes of the st-serum donor and of the two persons whose red ells had reacted with the test serum gave the followg results:

B. Chr. (test-serum donor): *A*, *CDe/c e*, *MNs*, *e(a+)*, *P*, *k/k*.

F. K.-N.: *O cde/cde*, *MNs*, *Le(a−)*, *P*, *k/k*, *u(a−)*, *Fy(a−)*, *Jk(a+)*.

S. S.: *O cde/cde*, *MNs*, *K*, *Le(a−)*, *p/p*.

Studies of the families of F. K.-N. and S. S. have ot revealed other persons giving positive reactions with the test serum; but unfortunately it has been impossible to draw any conclusions concerning inheritance from the results obtained in the available family material. Seven relatives of F. K.-N., including two brothers, one sister and the mother, and three relatives of S. S., two brothers and one sister, have been investigated.

The test serum has been investigated by Miss Mia van der Hart and Dr. J. J. van Loghem, who found that the antibody was different from antibodies reacting with the following 'private' blood-group antigens: *Vw* (Verweyst), *Rm* (Romunde) and *Vis* (Wright). Testing against 150 blood samples chosen at random gave negative results. The test serum was also investigated by Dr. A. E. Mourant, of the Lister Institute, London. He stated that the antiserum was not identical with those from Berrens, Graydon, Wright and two other 'family' antisera which are as yet unpublished. Dr. E. Freiesleben has tested the serum against thirty-nine random blood samples, also with negative results. Thus, including my own investigations, the serum has been tested against a total of five hundred random blood samples, of which only two gave positive reactions, which gives a frequency of 0·4 per cent. The antibody has been named anti-$Chr^a$ on the supposition that an anti-$Chr^b$ reacting with a very common blood-group antigen may exist.

I wish to thank Dr. A. E. Mourant and Dr. Dorothy M. Parkin, of the Lister Institute, London, Miss Mia van der Hart and Dr. J. J. van Loghem, Amsterdam, and Dr. E. Freiesleben, of Statens Seruminstitut, Copenhagen, who all assisted me in the serological investigations.

This work was aided by grants from the Anders Hasselbalch Anti-Leukæmia Foundation and C. P. Schepler and Wife's Bequest, the Irma Foundation.

## Some Notably High Acuities of Taste for Phenylthiocarbamide

In the course of a recent study of the thresholds of taste for phenylthiocarbamide (phenylthiourea) of members of a division of the Malayan Negritos, some extraordinarily high acuities were encountered.

The Negritos under study belonged to the Kintak Bong division, most of the few remaining members of which are at present living in the Baling district of the State of Kedah, Federation of Malaya. They are probably the 'purest' of the Negritos still living in the Malay Peninsula. The phenylthiocarbamide solutions employed in the work comprised a series numbered 0, 1, 2, . . . 18, the concentration of the substance being $2{\cdot}60 \times 2^{-n}$ gm. per litre, where $n$ is the solution number.

Three of the youths, aged seventeen, eighteen and fifteen years, were able successfully to distinguish in sorting trials between the solvent (distilled water) and solutions numbered 18, 17 and 16, respectively, the chance of success by guesswork being 0·125 in each case. Assuming that guesswork actually played no part in the trials, we may accept the respective solution as having set an upper limit to the threshold concentration in each case. These concentrations are lower than the lowest that appear to have been used by other workers elsewhere[1–3], and I wish to direct attention to the high acuities of taste for phenylthiocarbamide possessed by these subjects, the first-mentioned in particular.

Bitterness appears to be the taste sensation most readily evoked by appropriate substances, of which brucine, strychnine and quinine are among the most potent, brucine being accepted (apparently) as the most potent known and, on a weight basis, some twelve times more effective than quinine and four times more effective than strychnine[4]. Thresholds for quinine have been investigated fairly extensively. Recent upper-limit values obtained by Harris and Kalmus[2] for thirty-eight subjects range from $2 \cdot 4 \times 10^{-6}$ to $5 \cdot 7 \times 10^{-6}$ molar, calculated as quinine from the quinine sulphate (anhydrous ?) they used, and were obtained by sorting trials requiring discrimination between solvent and solution. Moncrieff[4] has discussed results varying from $4 \times 10^{-5}$ to $1 \cdot 5 \times 10^{-6}$ molar. A result reported by Kiesow[5] (quoted by Fulton[6]) corresponds with $1 \cdot 3 \times 10^{-6}$ molar quinine solution, calculated from the quinine sulphate (dihydrate ?) employed. A value, $1 \cdot 5 \times 10^{-7}$ molar, quoted by Dethier and Chadwick[7] and by Jahn and Wulff[8], appears to have arisen from a mistake in calculation. Thus, $1 \cdot 3 \times 10^{-6}$ molar appears to be the lowest recorded threshold concentration for quinine and, on the basis of the weight ratios mentioned above, a threshold concentration of $1 \times 10^{-7}$ molar might be expected for a very acute taster of brucine.

Phenylthiocarbamide belongs to a group of substances the threshold concentration of each of which covers a very wide range in a human population and is distributed bimodally. It is normally classed as 'bitter'; but it is well known that in the neighbourhood of their thresholds subjects may be inclined to characterize the taste as other than bitter, though usually describing it as 'bitter' at somewhat higher concentrations. Thus, the first-mentioned subject described the taste of solution 18 as 'sour', as did the second describe the taste of solution 17, and the third the taste of solution 16. The third described the taste of solution 14 as 'bitter and sweet'.

As the concentration of solution 18 is $9 \cdot 9$ μgm. of phenylthiocarbamide per litre, namely, $6 \cdot 5 \times 10^{-8}$ molar, the first-mentioned subject seems to enjoy the distinction of possessing for phenylthiocarbamide a higher acuity of taste than has been recorded for any other subject tasting any substance.

The volume of solution transferred to these subjects' mouths for tasting purposes was only $2 \cdot 5$ ml. on any one occasion. It contained, therefore, in the particular case under discussion, only $0 \cdot 025$ μgm. of phenylthiocarbamide (namely, $1 \cdot 6 \times 10^{-13}$ mole or about $4 \times 10^{11}$ molecules), and it is unlikely that even all this small amount was involved in reactions at the taste-buds. If Moncrieff's[4] estimate, that $0 \cdot 05$ ml. of solution properly applied should be sufficient for taste-testing, is correct, then this subject may have been able to detect a quantity of phenylthiocarbamide as minute as $8 \times 10^{9}$ molecules.

In passing, it is of interest to record that, in contradistinction to this high acuity, two female members of the same ethnic group were unable to distinguish even solution 0 from the solvent. It is the widest range of acuities we have encountered in any of the six Malaya-domiciled ethnic groups th we have examined.

## A New Form of Male Sterility in *Nicotian tabacum* L.

MALE sterility in tobacco has been reporte previously by Clayton[1] in advanced back-cro generations of two interspecific crosses betwee *Nicotiana debneyi* and *N. megalosiphon* as fema parents, and *N. tabacum* as pollen parent. E suggested that the cause may be incompatibilit

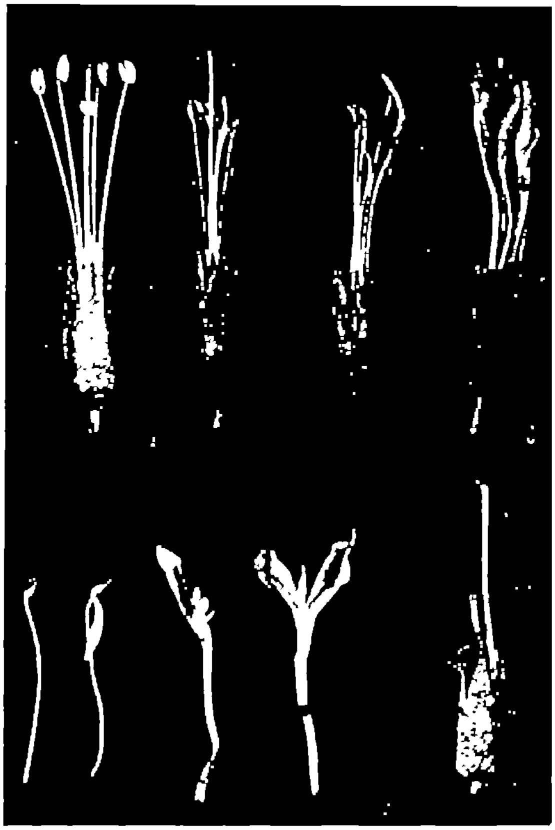

Fig. 1. Normal anthers observed in variety American Joiner and first-generation progeny of the new male sterile form (*a*) are compared with types of dissected flowers of the new male sterile form (*b*), individual petaloid stamens of the new male sterile form (*c*), and a dissected flower of variety Male Sterile 402 (*d*). The latter was derived from an *N. debneyi* × *N. tabacum* hybrid and generally contains one or more aborted stamens which may be fused in groups of two or more or with the stigma

tween the cytoplasmic constituents of the former d the nuclear constituents of the latter.

A new form of male sterility was observed here ring the 1953–54 season, which may be conditioned genetic rather than cytoplasmic factors. It peared spontaneously in plants of flue-cured riety American Joiner grown from seed several ars old. Plants from the same seed this current ason again exhibited one male sterile to about twelve rmal plants. Male sterile flowers are characterized petalody of the stamens, slightly reduced corolla e and lighter coloration (see Fig. 1). Even where dimentary anther-like structures were present, no llen was detected. In a small proportion of flowers e corolla was four-lobed and accompanied by four orted stamens.

This new male sterile form was crossed with normal ants of American Joiner, and the $F_1$ generation oduced only normal fertile flowers. A study of the ode of inheritance and possible linkage relationships s been initiated.

## Size Variations of Septate Wood Fibres in *Pithecolobium dulce* Benth.

In a recent abstract, Spackman and Swamy[1] ate that septate wood fibres "exhibit considerable riation in size, structure and contents. In most stances these elements are considerably longer than e cambial initials from which they were derived. some forms, however, the elongation has been ght and in others no elongation has taken place d the elements are essentially cambiform". It is edless to say that the above statements were of a sual nature and were not substantiated by actual monstration.

The septate fibre is an unusual cell type in two portant ways. First, it illustrates that lignification not a necessary concomitant of the death of the otoplast, but that the protoplast continues to hibit dynamic activities even after the comete lignification of the secondary wall. Secondly, is is a cell type modified to perform a dual function, mely, affording mechanical strength, on which the nction of storage has become superimposed. The ailable information on the origin, distribution and haviour of this important category of cells of the condary xylem is admittedly meagre.

Exploratory investigations indicate that this cell pe occurs sporadically in many (about a hundred) of e dicotyledonous families and that the proportion this cell type to others of the secondary xylem is riable not only among genera and species but also ithin a single individual. There are also instances here the septate fibres are confined only to a particlar sector of the stem or branch, or occur only in the rly or later formed parts of the secondary xylem. uch more extensive and intensive investigations this remarkable cell type are necessary in order understand clearly its exact morphological and nctional features.

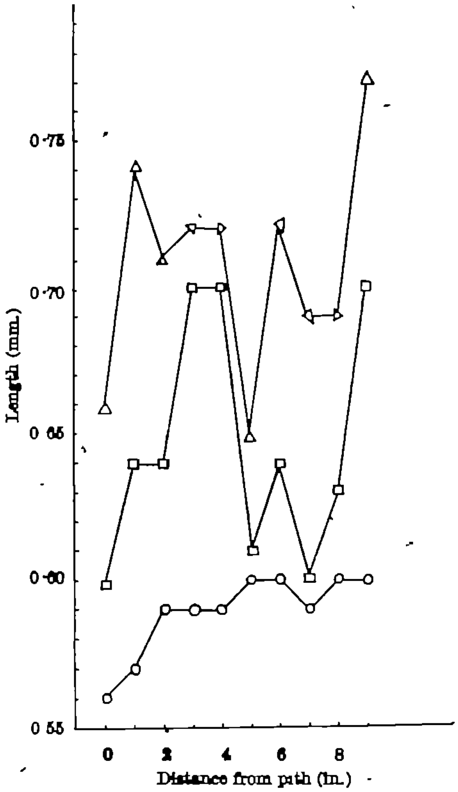

Fig. 1. Length-on-age curves illustrating variations of vessels (bottom), non-septate (middle) and septate fibres (top)

In *Pithecolobium dulce* Benth., the septate fibres are intermixed with the non-septate ones throughout the secondary xylem. A disk of 9-in. radius from two feet above ground-level was available for investigation. Measurements of tracheal elements were taken at every successive inch from the centre along the radius, and the data thus obtained were statistically analysed. The results may be summarized as follows (Fig. 1): The vessel members show a gradual increase in length in the early stages (until the second inch from the centre), but afterwards their length is subject to very little fluctuation. The non-septate fibres as well as the septate fibres in the early stages behave in a manner similar to the vessels in regard to their linear dimensions; but later their length is subject to considerable variations. The most remarkable feature that has emerged from the present study concerns the total independence of the septate and non-septate fibres in regard to their respective linear dimensions. The length-on-age curves for these two cell types are more or less parallel. However, it is significant that the septate fibres are not only longer than the non-septate ones from the initial stages, but also that the same relative linear values are maintained throughout ontogeny.

# An Apparent Change from Cytoplasmic to Nuclear Control of a Form of Chlorophyll Deficiency in *Gossypium arboreum* L.

THE occasional occurrence of variegated plants in *Gossypium herbaceum* race *Wightianum* has been reported by Gopalratnam[1], and in *Gossypium arboreum* race *sinense* by Feng[2], who also reported typical maternal inheritance.

Variegated plants have frequently been observed at this Institute in *G. arboreum* race *bengalense*. On one of these plants a bud from a chlorophyll-deficient area was forced into growth by appropriate pruning, giving rise to two flowers with chlorophyll-deficient boll, calyx, bracts and pedicel. These two flowers were selfed and the pollen also used for pollinating several types of normal green.

Selfing resulted in two progenies with twelve and thirteen yellow seedlings which died shortly after germination.

The crosses of normal green × deficient gave sixteen plants all of which were green.

From the sixteen $F_1$ plants, sixteen $F_2$ families were raised. The $F_2$ families exhibited two types of behaviour.

(1) *Normal Mendelian segregation.* Family *B*6 gave eighty-six plants of which sixty-seven were green and nineteen yellow deficient—a close approximation to the usual 3 : 1 ratio. The results of $F_3$, $F_4$ and $F_5$ confirmed the mode of inheritance as monogenic. Chlorophyll deficiency, however, showed a progressive increase in viability, and in $F_5$ and subsequent generations it was possible to grow deficient plants to maturity. They flowered well in pots, the first year's growth producing yellow-green leaves, while the leaves in the second year were almost full green, with only the growing-point yellow-green. Crosses were then made reciprocally between the new type of viable deficient and normal green. In $F_1$ green was fully dominant with 3 : 1 segregation of green to deficient in $F_2$, thus: green × deficient, 80 : 19; deficient × green, 108 : 29. A slight excess of green plants is found.

(2) *Maternal inheritance.* The $F_2$ families from the other fifteen crosses threw only greens—a total of 1,879 plants being recorded. This absence of segregation conforms to the usual type of cytoplasmically determined inheritance.

Therefore, out of sixteen crosses between female green and male chlorophyll-deficient from a deficient region of a variegated cotton plant, fifteen exhibited maternal (cytoplasmic) inheritance, while in the remaining family inheritance was nuclear and monogenic, with mutation from green to deficient in one locus as a possible explanation. This transition from cytoplasmic to nuclear control has apparently not been recorded in other plants. The improvement in viability of deficients from lethality to the condition of fertility is possibly due to progressive reverse plastid mutation.

I am indebted to Prof. S. C. Harland for his help in writing this communication, and to Mr. R. B. Sethi, director of the Indore Institute of Plant Industry, for permission to publish it.

# Synthesis and Properties of S-Alanyl Coenzyme *A*

S-ALANYL coenzyme *A* has been prepared l aqueous transfer of the alanyl residue from S-alan thiophenol hydrochloride to coenzyme *A* (Co*A*—SH in a manner similar to that used for the synthes of S-alanyl glutathione[1], and other S-acyl com pounds[2-4]:

$$\mathrm{PhSCOCH(CH_3)NH_3^+Cl^-} + \mathrm{Co}A\mathrm{{-}SH} \rightarrow$$
$$\mathrm{PhSH} + \mathrm{Co}A\mathrm{{-}SCOCH(CH_3)NH_3^+Cl^-}$$

Due to the small quantities of Co*A*—SH availab and the lability of S-alanyl coenzyme *A*, the produ could not be isolated by classical methods, that i as a metal salt. However, S-alanyl coenzyme *A* w successfully isolated in the pure state by pap electrophoresis (50 V./cm.), as it migrates at a slow rate than Co*A*—SH.

50 mgm. (70 per cent pure) Co*A*—SH and 25 mgm of S-alanyl thiophenol hydrochloride were dissolve in 0·2 ml. of water. The *p*H of the solution wa adjusted to 5–6 by means of the dropwise additio of 2 *N* sodium hydroxide solution. The reactio solution was then placed in a cold room at 4° C. f three days. The product was separated and purifie by paper electrophoresis in a neutral buffer (pyridine acetic acid : water, 10 : 1 : 89). (It was found necessar to use several 35-cm. wide paper sheets, owing t the low capacity of the paper.) The buffer solutio was removed from the electropherogram by freez drying, and the area which contained S-alan coenzyme *A* was cut out and eluted at low tempera ture with water. The water solution of S-alan coenzyme *A* was then freeze-dried. The yield wa 20 mgm.

A fresh solution of S-alanyl coenzyme *A*, subjecte to paper electrophoresis, exhibited one identica spot when developed with ninhydrin, in ultra-viole light, and with nitroprusside ammonia. The nitr prusside spot was slightly delayed, appearing withi 1–2 min. The paper electropherogram of an age solution also contained a positive ninhydrin spot fo alanine.

When a sample of S-alanyl coenzyme *A* was in cubated for 2–3 hr. with an excess of glutamic aci at *p*H 8 in a sodium bicarbonate buffer solution a 20° C., a new ninhydrin reactive compound arose This compound we believe to be alanyl-glutamic aci (Fig. 1). In the presence of pigeon-liver homogenate

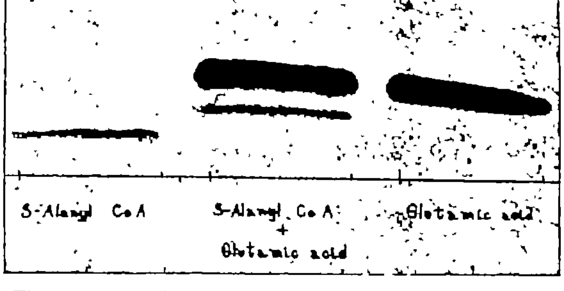

Fig. 1. Electropherogram of S-alanyl coenzyme *A* – glutamic acid incubation mixture. The formation of alanyl-glutamic acid is shown in the middle column where it has migrated at a slower rate than glutamic acid (right column), but faster than S-alanyl coenzyme *A* (left column). Composition of incubation mixture: 0·1 ml. of 0·5 *M* sodium bicarbonate, 0·05 ml. of 0·1 *M* glutamic acid, 0·05 ml. of 2 mgm./ml. S-alanyl coenzyme *A*

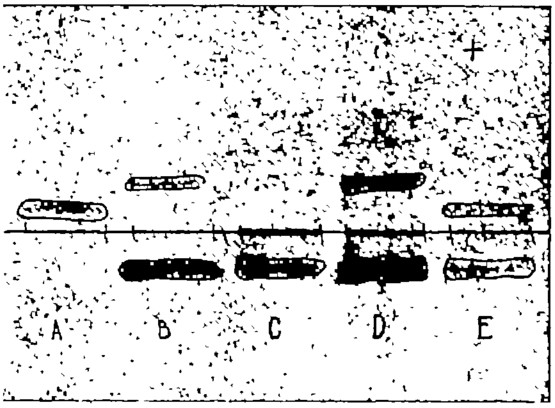

Fig. 2. Action of S-alanyl coenzyme *A* deacylase. *A*, S-alanyl coenzyme *A*; *B*, S-alanyl glutathione, lower spot (traces glutathione upper spot); *C*, S-alanyl coenzyme *A* + deacylase, spot: alanine; *D*, S-alanyl glutathione + S-alanyl coenzyme *A* deacylase; *E*, S-alanyl coenzyme *A* + glyoxalase II. Composition of incubation mixtures: 0·05 ml. Sorensen phosphate buffer *p*H 5·4, 0·05 ml. enzyme solution, 0·05 S-alanyl compound (2 mgm./ml.). Time, 15 min. at 20° C.

rapid enzymatic hydrolysis of S-alanyl coenzyme *A* ) alanine and Co*A*—SH takes place. The active eacylase is not identical with glyoxalase II [5]. A pure mple of glyoxalase II rapidly cleaves S-alanyl lutathione[1]; however, it does not, or only very owly, hydrolyse S-alanyl coenzyme *A* (Fig. 2).

S-Alanyl coenzyme *A* deacylase is present mainly the mitochondria and microsome fractions of liver. owever, it is also present in smaller concentration the plasma fraction of the liver homogenate.

Attempts to demonstrate an enzymatic acyl transr of the alanyl group to other amino-acids or to the H group of cysteine have been unsuccessful thus far, ecause of the rapid, possibly competing, enzymatic ydrolysis of S-alanyl coenzyme *A*.

Coenzyme *A* was kindly given to us for experiental purposes by C. H. Boehringer Sohn, ngelheim.

## Meaning of 'Turnover' in Biochemistry

In a recent communication, Kleiber[1] has discussed wo different definitions of the term 'turnover-rate'. ome workers, particularly those associated with haikoff, regard the turnover-rate as the rate at hich a substance is replaced in the tissue cells lefinition 1). This is essentially the concentration of e substance in the tissue divided by the turnoverme. Others, including Kleiber, consider it to be the te at which the whole 'pool' of the substance, howver large or small, is replaced in the tissue, given y the reciprocal of the turnover-time (definition 2). oth groups agree that the turnover-time is the biological 'average life', given by 1·44 × biological half-life.

These concepts are each valuable; but the turnover-rate as defined by Kleiber tells no more about physiological events than does the turnover-time. Two tissues could have the same turnover-time and yet contain very different concentrations of the substance under consideration. They would have the same turnover-rate according to Kleiber, yet unit weight of the one tissue would metabolize the substance much more rapidly than unit weight of the other.

The dorsolateral prostate of the rat contains more than ten times as much zinc as the ventral prostate[2] per unit weight. The results of turnover experiments with these tissues, using zinc-65, are given in Table 1. The data are taken from a paper which is being prepared in collaboration with Miss M. I. Fischer and Dr. B. E. Riedel. The turnover-rate of zinc in the dorsolateral prostate is nearly ten times as great as in the ventral prostate according to definition 1; but by definition 2 the turnover-rate of the ventral prostate is actually greater than that of the dorsolateral prostate.

Table 1. Turnover of Zinc in the Prostate Glands of the Rat

| | Ventral prostate | Dorsolateral prostate |
|---|---|---|
| Mean zinc content (µgm./gm.) | 13 5 | 168 |
| Biological half-life ($T_{1/2}$) (days) | 7 6 | 9·9 |
| Turnover-time ($T_{1/2}$ × 1·44) (days) | 10 9 | 14·3 |
| Turnover-rate (1)* (µgm. Zn/gm./day) | 1 24 | 11·8 |
| Turnover-rate (2)* (fraction of pool/day) | 0 092 | 0 064 |

* Turnover-rate (1) = µgm. Zn/gm. tissue divided by turnover-time. Turnover-rate (2) = reciprocal of turnover-time.

Many tracer experiments are done without estimation of the concentration of the substance under investigation, and this applies particularly to work with trace elements, especially those which do not occur naturally in the body in measurable amounts. It may partly be for this reason that most workers have defined turnover-rate as the reciprocal of turnover-time. However, the Chaikoff concept of turnover-rate is of such physiological significance that it should have a name. In Table 1, turnover-rate (1) could be described as the zinc turnover-rate, and (2) as the zinc pool turnover-rate; but these terms are sufficiently similar to lead to confusion. It is suggested that the Chaikoff turnover-rate (1) should be called the flux-rate, retaining 'turnover-rate' for the definition favoured by Kleiber. The word 'flux' has been used in a similar sense by Reiner[3] in a theoretical discussion of the implications of turnover-rate calculations.

Zilversmit[4] has suggested that 'turnover-rate' should continue to apply to definition 1, and has proposed an alternative term for definition 2. I believe that this would be a mistake. An extensive review of the literature has shown that 'turnover-rate' is defined according to definition 2 in the great majority of cases and any alteration would add to the confusion which we all wish to avoid.

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Experimental Officer (with a pass degree or at least G.C.E. at advanced level) in the Plant Breeding Section—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick (August 17).

Senior Psychologist in the Department of Psychological Medicine, to be responsible for the diagnostic testing of adults and children—The Clerk to the Governors, St. Thomas's Hospital, London, S.E.1 (August 17).

Lecturer in Geology, with special reference to petrology—Head of the Department of Geology, Imperial College of Science and Technology, Prince Consort Road, London, S.W.7 (August 19).

Experimental Officers and Assistant Experimental Officers (with at least H.S.C. (science) or equivalent), at the Ministry of Supply National Gas Turbine Establishment, near Farnborough, Hants, for work concerned with problems of combustion, heat transfer, aerodynamics, projects and performance instrumentation and application of electronics in gas turbine research—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting C.146/5A (August 27).

Research Demonstrator in Physics—The Registrar, The University, Sheffield (August 27).

Assistant in Natural History—The Secretary, The University, Aberdeen (August 31).

Director of the University Gardens at Ness, Neston, Wirral—The Registrar, The University, Liverpool (August 31).

Research Assistant in the Physics Department, for work with Prof. K. G. Emeléus either in spectroscopy or on gaseous conductors—The Secretary, Queen's University, Belfast (August 31).

Research Assistant (with a degree in physics and preferably with some research experience) in the Department of Physics, to undertake wave-length measurements of high precision, using a reflecting echelon interferometer—The Registrar, King's College, Newcastle-upon-Tyne (August 31).

Research Fellow in Mathematical Physics at the University of Adelaide, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Adelaide, August 31).

Lecturer in Comparative Social Administration at Victoria University College (University of New Zealand)—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, September 1).

Assistant Lecturer or Lecturer in the Department of Pharmacology and Therapeutics—The Registrar, The University, Liverpool (September 3).

Assistant Lecturer in Metallurgy—The Registrar, The University, Manchester 13 (September 7).

Lecturer in the Department of Botany at the University of New England, Armidale, New South Wales, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, September 12).

Professor of Genetics—The Registrar, University of Adelaide, South Australia (September 15).

Reader in Mechanical Engineering at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong, September 15).

Lecturer (first-class honours graduate in mathematics, and preferably with special interests in some branch of applied mathematics or statistics) in Mathematics—The Registrar, College of Technology, Manchester 1 (September 19).

Lecturer in Geology at the University of Tasmania—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Tasmania, September 30).

Senior Lecturer in Biochemistry at Victoria University College, Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, September 30).

Assistant Lecturer (honours graduate in chemistry, with research experience and special interests in physical or inorganic chemistry) in Chemistry—The Registrar, College of Technology, Manchester 1 (October 1).

Lecturer (with experience in some of the following subjects: X-ray crystallography, non-destructive testing, optical methods of examination, gauging methods and instrumentation of plant) in Industrial Metallurgy—The Registrar, The University, Birmingham 15 (October 15).

Assistant Biochemist (Basic grade) (with a B.Sc. degree with honours in chemistry or biochemistry, or an equivalent qualification) in the Department of Pathology—The Group Secretary, The Royal Hospital, Wolverhampton.

Biochemist (with an honours degree in chemistry or biochemistry, and with one or two years biochemical research experience), to assist in research work in the Special Unit for Juvenile Rheumatism—The Secretary, Canadian Red Cross Memorial Hospital, Taplow, near Maidenhead.

Chemical Engineers and Chemists (with an honours degree in chemistry or chemical engineering, or corporate membership of a relevant recognized professional institution or equivalent qualifications) to work in a group concerned with the industrial aspects of atomic energy—The Recruitment Officer, United Kingdom Atomic Energy Authority, Research and Development Branch, Industrial Group Headquarters, Risley, near Warrington, quoting Ref. 1,057.

Circuit Engineer (with a knowledge of pulse techniques and video and r.f. amplifiers, and a recognized technical qualification) in the Nuclear Physics Research Laboratory to work on design of electronic equipment associated with the experimental programme of the 156 in. synchrocyclotron—The Registrar, The University, Liverpool, quoting Ref. No. 220.

Experimental Officer or Assistant Experimental Officer (with a degree in geology, chemistry or physics), for work on the X-ray and differential thermal examination of clays (Soil Survey of England and Wales)—The Secretary, Rothamsted Experimenta Station, Harpenden, Herts.

Lecturer in Animal Husbandry—The Principal, Shuttlewort College, Old Warden Park, Biggleswade, Beds.

Lecturer (with a good honours degree in electrical engineerin and with experience in servomechanisms) in Electronics—Th Secretary, Royal Technical College, Glasgow.

Principal Scientific Officer (with a first- or second-class honour degree or equivalent in mathematics, physics or engineering, and wit instrument experience), at the Ministry of Supply Headquarters i London, to be in charge of a section responsible for research and development of fire-control equipment for military aircraft and ancillary equipment—The Ministry of Labour and National Service Technical and Scientific Register (K), 26 King Street, London, S.W.1 quoting A.275/5A.

# EDUCATIONAL PROBLEMS OF THE COLONIAL TERRITORIES

UST on twenty years ago, in September 1937, the Commission on Higher Education in East Africa, hich was under the chairmanship of Earl De La arr, issued its report. The Commission took as iomatic that the primary need of East Africa was e improvement of health and agriculture, and that ch improvement could best be achieved through e general education of Africans and by training in fficient numbers qualified African experts. Its first commendation, that education in East Africa ould be based upon the need of the community d should be closely related to environment, was nply endorsed two years ago by the Binns report; d the recommendations relating to education in e recent report of the East Africa Royal Comission of 1953–55 (see *Nature*, July 16, p. 87) are milarly based. It is not too much to say that lucation lies at the root of almost all the latter ommission's recommendations: they cannot be plemented effectively unless an educational policy such broad lines is formulated and executed aginatively and with vision as well as more gently and on a larger scale than has yet been done.

This is not to disparage the progress that has ready been made or to belittle the very considerle achievements of the past two decades. It is ther to emphasize that it is only through education at the African can adapt himself to use the w opportunities which are opening to him in dustry and on the land; and also gain a clearer nderstanding of the changes in traditional African ociety which are necessary to enable Africans to joy the higher standards of living they desire. ithout a vigorous and wisely concerted educational licy, the conditions encouraging the exercise of tivities favourable to progress cannot be secured, the co-operation and understanding between the ces essential for harmonious development establhed.

This point is very firmly emphasized by the Comission, which insists that the co-operation of the frican is essential for the effective development of ast Africa and that this co-operation cannot be cured without dispelling the fears and suspicions hich hinder it at present. To that end education is effective a weapon as it is in promoting the skill d knowledge the African needs for using the new pportunities which confront him. Nor is it any less nportant in assisting adaptation to the changes in aditional tribal economy which a modern and more roductive system demands.

Much that the Commission has to say on education essentially a re-statement of the findings of the inns Committee. That Committee saw in a full, comrehensive and balanced education a major solvent f the economic and social problems of East Africa, nd it emphasized that the more liberal education it ought for Africans must be based on their own frican environment and on their own way of life; nd particularly it stressed the paramount importance of agriculture and an attack on agricultural ignorance. Again, it urged that technological education should be developed to keep pace with industrial expansion, in order to enable Africans to make their maximum contribution as skilled workers in accordance with the opportunities of each area. The Binns Committee emphasized, too, the necessity for a close connexion between technical education and industry, and pointed out that successful technical education can only be based on a good general education.

The East African Commission naturally did not pursue the requirements of educational policy in any detail; but it recognizes clearly enough that education is a fundamental service, on the adequacy and efficiency of which all other services depend. For example, new industrial development in Africa requires a large contribution from Africans, even if at present they cannot provide all the managerial ability and capital required; and it is important to enable Africans to acquire the special skill required in modern industry and to create conditions which will allow Africans to exercise the greatest degree of enterprise of which they are at present capable. The difficulties are not primarily financial: they are chiefly deficiencies in knowledge and experience, and a public policy concerned to promote direct African participation in new industrial development should concentrate on removing those deficiencies.

Though education is a basic factor, it is not the only one. Much industrial training will have to be provided by industry itself, although the emergence of a foreman class among the African workers themselves clearly will depend on raising the standards of education as well as on the quality of industrial training. Moreover, the low productivity of ordinary African labour is not due merely to the lack of technical skill but also to various factors, some of which—such as under-nourishment, poor physique, endemic disease and lack of interest in ordinary economic incentives—could be modified or removed by appropriate public policy.

Specifically, the Commission advocates carrying elementary education to a stage at which it will be of permanent benefit to all growing children able to profit by it. Free universal education is, however, a long-term objective. For the present, the Commission suggests providing education for all pupils, at fees which will not exclude any, to the beginning of the intermediate stage, and in towns to the end of the intermediate stage. Secondary education should be obtainable by those prepared to pay for it, and supported by a wide and liberal system of bursaries for those unable to pay but showing clear promise and ability. The proposals of the Binns Committee for eliminating waste and ensuring that pupils complete their courses are supported, and it is suggested that priority should be given to the expansion of intermediate education, preferably as an adjunct to existing primary schools, even if this means temporarily retarding direct progress with primary education. It is emphasized that a higher standard of training in technical education can scarcely be established except on the basis of eight years primary education.

It is a little surprising, accordingly, in view of this long-established opinion as to the fundamental importance of education in Africa, to find so few references to education in the schemes made under the Colonial Development and Welfare Acts in the returns for 1954–55*. Apart from £37,116 for the expansion of education services in Zanzibar and a further £37,000 for the construction of primary schools and teachers' houses and £7,000 for the adaptation of Kampala Technical School, the only major schemes for education financed in this way are in West Africa, where £228,700 is provided for the construction of students' hostels, lecture theatre, assembly hall and gymnasium for the Nigerian College of Arts, Science and Technology. Under other schemes, £99,314 is provided for the construction of senior staff housing for the Nigerian College of Arts, Science and Technology, and £42,613 for additional accommodation for students and staff at University College, Ibadan. Out of the further £3,763,351 contributed to the development plan for Nigeria, however, £527,828 is earmarked for general education and £455,478 for technical education.

Education, moreover, receives due emphasis in the recent report on the Colonial Territories, 1954–55†, which, noting the continued expansion of educational facilities and the making of new provision for technical and higher technical education in several territories, points out that at the end of 1954 the number of students at the three universities and four university colleges in these territories exceeded four thousand. Enrolment at the Kumasi College of Technology increased to 580, of whom 62 were taking professional courses in engineering; and good progress was made towards the completion of the new buildings in Nairobi of the Royal Technical College of East Africa, for which a further grant of £107,000 was approved from Colonial Development and Welfare Funds.

It is in the context of these findings of the East Africa Commission and the general survey presented in "The Colonial Territories" that the significance of the achievements recorded by the Inter-University Council for Higher Education Overseas in its recent survey of the period 1946–54, and of the findings of the report by PEP entitled "Colonial Students in Britain"‡, are best appreciated. Indeed, "The Colonial Territories, 1954–55" contains a wealth of material which could be used for combating the complete indifference of the general British public to their own great Colonial inheritance, which was noted by PEP, and it should be for consideration whether the presentation of that annual report could be varied so as to deal more effectively with an ignoran which is both generally dismaying to Colonial studen and hinders sound judgment and wise decisions issues affecting all those territories for which Brit is still politically responsible.

To combat such ignorance is the more importa when we consider the extent to which these questio are interlocked. It is not simply a matter of pr viding more information or other effective action promote understanding between British and Colon peoples. The growth of the Colonial student popu tion from about 1,000 in 1946 to more than 10,0 in 1955 reflects the need of the Colonial territories trained men and women in order to accelerate even maintain development; and that need mu in large part be met from overseas until the n university institutions in those territories come maturity. Although only some thirty-five per cent such students are at universities, the remaind attending polytechnics, training colleges, or studyi under the auspices of such bodies as the Inns Court, they occupy places in British universi institutions to the extent of some two per cent at time when we are seriously concerned with t ability of those institutions to provide a sufficien of scientific and technical man-power for the dire needs of Britain.

Colonial education is, moreover, directly link with this question of scientific and technical ma power, as both the report of the Inter-Universit Council and the latest report from the Adviso Council on Scientific Policy (Cmd. 9537. Londo H.M.S.O. 6*d.* net) indicate. The young universiti overseas have close ties with universities in Brita and receive from them invaluable assistance, whi makes none the less heavy demands on staff. Suc special co-operation will be needed as fully in t immediate future as in the past. Much the same ca be said of research. The Advisory Council estimat that only some 450 scientists are at present engage in Colonial research, and of these less than o hundred are members of the Colonial Researc Service. This number is quite inadequate for t important problems awaiting attention, and unt the Colonial universities and research institutio have developed considerably, any expansion research must draw largely on the limited suppli of scientific and technical man-power in Britain itsel

The postgraduate scholarships recommended b the Inter-University Council in another connexio may offer some contribution here; but it is evide that in the present man-power situation the needs the Colonial territories require the most caref consideration. This factor, as well as their financi needs, should receive due weight in determini priorities and the allocation of our resources, n least when regard is had to the implications of suc new developments as that of nuclear power f Britain's own economy. The potentialities of th export trade stressed by Sir Francis Simon recent depend to some extent on the existence of traine men and women in the under-developed area and on the level of general and technical educatio there.

‡ Colonial Students in Britain: a Report by PEP. Pp. ix+257. (London: PEP (Political and Economic Planning), 1955.) 21*s.*

As the PEP report on Colonial students notes, in ost territories the demand for professional and hnical skill is changing rapidly. Often the response these changes is too slow and development is peded because people with the right qualifications not available at the right time. Students arriving Britain are not always as well informed as they ould be about these changes, and PEP rightly esses the importance of systematic efforts to vise students and parents as to vocational suit- ility and opportunities.

This is one of the most important functions of the ident advisory service which PEP recommends ould be set up in each territory. Too many Colonial idents reach Britain inadequately prepared and equipped for their studies; but the student visory service should not be concerned with the itine inquiries which all educational institutions in itain are bound to make about all candidates for mission. PEP deprecates the students leaving me until they have obtained at least the minimum alifications they require for the courses they pro- se to take overseas, and urges that the maximum vantage should be taken of local facilities for gher education; nor should students proceed over- is before they have received admission to an ucational institution. The local student advisory rvice should make a continuous review of students' airs and problems, and there should be a corre- onding service in Britain to advise and help to ice Colonial students. Moreover, the British uncil facilities should no longer be restricted to idents recommended by governments but should available to all Colonial students.

There are other sensible suggestions dealing with ch matters as short preparatory courses for the s-mature students and the provision of accom- odation; but the vital issue is made abundantly in—more careful selection by the Colonial thorities and further preparation on the part of student. It is here above all that the recom- mdations are linked with the findings of the Royal mmission on East Africa and the observations of Inter-University Council for Higher Education erseas. On one hand, they imply greater local orts to provide adequate secondary and technical ucation up to sixth-form standard or its equivalent. the other, they confirm the wisdom of developing lonial universities, where ideally the sorting process ıld be effected so that mainly postgraduate students ıld be sent on for further training or specialized rk—a development itself retarded by the slow velopment of secondary education in both quality d quantity in the territories these institutions serve.

As the PEP report remarks, the increased flow of lonial students to Britain since the Second World ar reflects the fact that, although the facilities for gher education and specialized training in many lonial territories have been very greatly extended recent years, the advance has not been able to ep pace with the rapidly growing demand for ined men and women created by the accelerated npo of local political, social and economic develop- nt. Nor is it easy to see how, without grave detriment to standards or imposing excessive demands on the limited scientific man-power of Britain generally, as well as on the universities, the young institutions in the Colonies can be expanded rapidly to overtake that demand. Apart altogether from the fact that it is improbable certain types of education and training will be obtainable in these territories in the foreseeable future, the flow of students from the Colonial territories to Britain and some other countries is unlikely to diminish significantly for many years to come.

The relatively small number of Colonial students who are gaining the advantage of higher education and specialized training in Britain must thus bear early, and to a large extent, the responsibilities of leadership in the swiftly developing countries from which they come. Their attitude to, and relations with, Britain will be greatly influenced by their reception and experience as students in Britain. This is a paramount reason for attention to the sensible recommendations which the PEP report makes in regard to their welfare, and for the co-operation of the recognized professional associations and other bodies in the ways that are indicated.

But it is in the context of the expansion of the institutions of higher education in the Colonies that the Inter-University Council has some wise comments that need stressing. Noting that the progressive achievements in the provision of universities within the overseas territories during the past nine years have exceeded expectations, the Council remarks that the apparent ease with which the programme has been carried through to this point masks risks and dangers that may yet defeat or imperil the whole enterprise. One such danger—the growing signs of a demand for the establishment of more universities in the immediate future—bears particularly on this recommendation of the PEP group regarding the sorting out of students in the territory from which they come.

There may be political reasons for desiring a further university in a particular territory; but the consequence of such a step in a country where educational needs for the next decade might be better served by the provision of technical colleges could well be a dissipation of effort and resources, resulting in two starved institutions and a disastrous lowering of standards, not only in the so-called universities but equally in the public services and professions. The Inter-University Council and the PEP Group are at one in stressing the need for high standards and for resisting pressures to lower them. Political factors cannot indeed be ignored: local pride and support are vital to the success of any university, and it will always be a matter of delicate judgment to decide what weight should be given to political arguments when these conflict with technical and professional considerations.

Provided the academic issues and financial implications are fully and clearly stated, however, as the Inter-University Council seeks to ensure, there is the less risk either of a false step or of failure to keep alive the dynamic factors in the development of the overseas universities. The importance of that factor—of recognizing that the new universities are communities of men and women with pride and ambition in their subjects and in their institutions—is implicit in the PEP report and also in that from the Inter-University Council. Both reports present a great challenge, not only to all directly concerned in the enterprises which they survey but also to the body of informed opinion in Britain which already appreciates how much is at stake, and how simple are some of the measures required to avoid waste of effort and frustration. Confidence and co-operation must take the place of distrust and suspicion towards Britain that endanger the political, economic and social development of the Colonial territories, and the ultimate evolution of self-governing States within the Commonwealth, which are the declared aims of British Colonial policy. An important step to meet that challenge is offered by the material collected in "The Colonial Territories, 1954–55" and elsewhere for the creation of an informed public opinion, alive to the responsibilities of Britain in those territories and sensitive to the needs of those peoples, whether they remain in their own territories, or seek to fit themselves in Britain to serve their countrymen.

# LOW-TEMPERATURE PHYSICS

## Progress in Low Temperature Physics

Edited by Prof. C. J. Gorter. (Series in Physics.) Pp. xii+418. (Amsterdam: North-Holland Publishing Company, 1955.) 30.50 guilders; 61*s.*; 8 dollars.

DURING the past ten years or so, the commercial availability of the Collins cryostat has enabled many new laboratories, particularly in the United States, but also in France, India, Japan and elsewhere, to work at liquid-helium temperatures, previously a monopoly of only a few specialized laboratories; and there has been, in consequence, an enormous expansion of activity in low-temperature physics. The appearance of this collection of review articles—about half from laboratories which have only recently entered the field—is therefore to be welcomed. Such review articles enable the research worker specializing in any one branch of low-temperature physics to keep up with progress in others without having to read all the original literature; because many of the principles and techniques are common to all branches, this may well give him new ideas for his own special problem as well as broadening his outlook.

The best method of presenting a review article depends very much on the nature and scope of the subject. For a rather limited topic, it is possible to give a critical survey of the experimental and theoretical situation, using tables and illustrative graphs with full references to the literature, in quite a short space. An admirable example of this style of treatment is E. F. Hammel's article on liquid helium-3, which guides the reader through a very tangled situation and shows just what has been achieved. A less-successful example is C. F. Squire's article on the effect of stress on superconductivity—an even more limited topic, but not sufficiently systematically presented and lacking an adequate theoretical discussion. At the other extreme there is the mu
wider topic, such as the technique of adiaba
demagnetization and its many applications, whi
demands a much larger space if coverage in f
detail is to be achieved. This approach has be
adopted by D. de Klerk and M. J. Steenland, wh
article on adiabatic demagnetization is the long
in the book (62 pages) and almost a monograph
its own right; it can be read with profit by anyo
who wishes to learn the subject in detail from t
beginning, but is perhaps unnecessarily detailed
the low-temperature physicist to whom the book
primarily addressed. Alternatively, this kind of to
can be treated in more general terms with no attem
at a complete build-up but with a selection of ill
trative examples; this is A. H. Cooke's approach
his interesting 20-page review on paramagne
crystals in use at low temperatures. Probably t
ideal lies between the two, assuming rather m
specialized theoretical knowledge than de Klerk a
Steenland but giving a rather more detailed develo
ment than Cooke.

Nearly all the articles are reviews of alrea
published work; but R. P. Feynman's article on t
application of quantum mechanics to the liqu
helium problem deserves special mention as being n
so much a review as an original contribution, in whi
he presents important new developments of
recent ideas, in a form assimilable by the expe
mental physicist. These new ideas stress t
importance of turbulence in the flow of liquid heliu
and are particularly suggestive for new experimen

The eighteen articles cover a wide variety
subjects; about half are concerned with the propert
of liquid helium and superconductors, and t
remainder deal with paramagnetism, antifer
magnetism, ferromagnetism, propagation of sou
and transport properties of gases. There is so
overlapping (between B. Serin's article on sup
conducting critical fields and J. G. Daunt's on el
tronic specific heats of metals, which might well ha
been combined) and the choice of detailed top
seems a little haphazard. It is, however, explain
in the editorial preface that this choice has be
governed partly by expediency (where the compete
authority was not available to deal with a particu
topic at the time) and partly by the existence
recent review articles on some topics which it seem
unnecessary to treat again for a while.

On the whole, the articles are successful
achieving their object, and it is to be hoped that t
valuable service rendered by this collection
articles will be continued in at least a second volun
Perhaps, however, in such a second volume the edi
might aim at rather greater uniformity in the sc
and level of treatment of the articles.

# FRUIT PRODUCTION

## The Fruit Year Book, 1955

(No. 8.) Edited by P. M. Synge and Lanning Rop
Pp. 142+30 plates. (London: Royal Horticultu
Society, 1954.) 10*s.*; 1.65 dollars.

ALTHOUGH the cultivation of fruit trees in t
specialized sense began early in the past centu
so much new knowledge of its problems and pote
tialities comes with each year that a year-book
necessary to record the progress. The complexit
of the situation are well portrayed in the pres

ume in a paper on the maintenance of healthy it clones, by R. V. Harris. Dealing particularly h a nuclear stock organization for the propagation tested healthy material, he shows that many fruit es and plants harbour 'latent' viruses without wing symptoms. Strawberries have a high degree tolerance in that they show little diminution of our when viruses are carried without causing nptoms. Raspberries and probably some tree its, on the other hand, often make but poor wth when 'latent' viruses are present—a pre- usly unsuspected cause of lack of vigour. Absence symptoms makes it impossible to maintain health roguing alone; hence the necessity for a care- ly controlled system of virus testing, the assess- nt of varietal reactions, and propagation under iditions where virus cannot be re-introduced.

). W. Greenham describes several types of soil nagement for the fruit grower, from clean culti- ion to permanent grass. He concludes that a table stand of grass and clover, mown frequently h a gang-machine, is in most cases the best form soil management for English orchards. Straw lches for soft fruit are also discussed; they are tively non-absorbent, and appear to act as 'non- rn valves' for the rainfall, and thereby conserve moisture, with considerable practical benefit.

'ree fruit yields fluctuate notoriously; A. P. ston finds that thinning the fruits to one per nty leaves gives good and regular crops. L. C. kwill shows that thinning on the large scale can accomplished by spraying with α-naphthalene tic acid in concentrations ranging from 5 to 50 ts per million, depending on the variety, the time r petal-fall, the degree of thinning required, the perature, and the nutritional status of the tree. also discusses the now well-established use of the e substance for reducing fruit drops at various es. Changes in the orchard insect fauna during present century are reviewed by A. M. Massee, o makes a plea for their ecological study as a ole. There are several other articles of more eral or regional interest, and the excellent plates l lustre to a well-produced volume.

John Grainger

# HUMAN BIOLOGY FOR THE MASSES

, the Great Adventure

Jean Rostand. (Discussions with Paul Bodin.) nslated by Alan Houghton Brodrick. Pp. 258. ndon: Hutchinson's Scientific and Technical blications, 1955.) 12s. 6d. net.

HIS book is an account of a series of conversa- tions on the French broadcasting system, which k place between Jean Rostand, a well-known nch biologist and, like his famous father, a man letters, and Paul Bodin, a distinguished poet, elist, journalist and man of science. In the talks, din played the part of a devil's advocate who was ill-informed on matters which excite public rest, while Rostand attempted to put the point view of a modern biologist-philosopher on topics cerned with heredity, sex, health and the future nankind. The radio talks were listened to by a e audience and have now been expanded by tand and Bodin into a book which is an admirable guide for those who wish to explore some of the broader paths in the field of current biology. Translation from the French has been made by A. H. Brodrick, himself well known for his contributions to the popularizing of science.

With Rostand's general point of view few modern biologists would quarrel, although his explanation of reasons for superfluous hair in the male is nonsense. Nor is he to be commended for the most obvious side-stepping of a question from Bodin dealing with birth control; perhaps, in France, the question should never have been put. This may also explain why a subject like miscegenation is dismissed in a sentence, although possibly here the translation may be at fault.

These, however, are trivial criticisms of a book which could reach many readers. Many of them will be shocked to learn that, in days of popular education and in a country like France, whose people are so proud of their ability to behave rationally, there are still about 3,460 astrologer-palmists in Paris alone. Here the man of science has cause to regret that the spread of scientific knowledge may even increase the credulity of those who possess a little scientific learning. One of the lessons from this book is that the mass of people are still prepared to believe anything, particularly if the new cult is served persuasively with the right amount of scientific jargon. Rostand and Bodin deserve praise for their efforts to remove some of the superstitions of 1955.

T. H. Hawkins

# HISTORY OF ASTRONOMY

The History of Astronomy

By Prof. Giorgio Abetti. (Translated from the Italian "Storia dell' Astronomia" by Betty Burr Abetti.) Pp. xviii + 345 + 34 plates. (London: Sidgwick and Jackson, Ltd., 1954.) 25s. net.

IN this book of more than three hundred pages Prof. G. Abetti gives the reader a straightforward summary of the history of astronomy. As he remarks in the preface, a book of this size "can be nothing but a summary of the vast amount of material which only a complete history could adequately present". He considers (Chapter 2) that the subject "may be arranged into three great periods corresponding to the history and civilization of the peoples of the Earth". First we have ancient astronomy, which can be traced back to about forty centuries before Christ and which can be considered to have ended with the decline of the Alexandrian school at about A.D. 650. Then comes medieval astronomy, which is mainly the astronomy of the Arabs and, to a small extent, that of the Romans. "But," comments Prof. Abetti, "the astronomy of these peoples, as also of the western Latins until Copernicus, is essentially nothing but a repetition of the Almagest of Ptolemy." Medieval astronomy is regarded by the author as extending up to about A.D. 1500. Between it and modern astronomy there is a transitional period of reformation, represented by the work of Copernicus, Tycho Brahe, Kepler, Galileo and Newton: "Through the work of these great men astronomy was launched on new and unthought-of paths to numerous and important conquests".

The modern era is considered to begin directly after Newton, and the book proceeds forward right up to the present day, Chapter 19 dealing with the developments of the twentieth century. It is always extremely difficult to include contemporary developments in writing a history of anything, and the author has wisely stated explicitly that his aim here is "to give an over-all glance at the results obtained in relatively recent times up to the present, without pretending to give the complete picture either of the subject matter or of the persons". Most readers will agree that Prof. Abetti has discharged this part of his task competently and fairly, and that the book would not have been so good, as it undoubtedly is, if Chapter 19 had been omitted. Any would-be critic will be well advised to ask himself whether he could do the job better.

In the chapters dealing with ancient astronomy, many readers will select Chapter 5 as the most interesting. This chapter gives an account of the school of Alexandria. A valuable feature is an earlier chapter, "Ancient Astronomers other than Greek", which deals successively with the astronomy of the Mesopotamians, the peoples of Central America, the Egyptians, the Jews, the Phœnicians, the Hindus and the Chinese. The last two come in for some courteous but definite 'debunking'.

The author explains in the preface that this "History", now translated for English-speaking readers, was written originally in Italian and that he has "lingered more, in the course of its development, on the Italian personalities and on their contributions to astronomical progress". I consider that Prof. Abetti's 'lingerings' have enhanced the value of the book. I particularly enjoyed the author's 'lingerings' over the work and careers of Toscanelli and of Secchi. The author is probably correct in claiming that the first period of the rise and development of astrophysics closed with the death of Ricco in 1910. The fact is that the contributions of Italians to astronomy are not so well known as they ought to be, and the 'lingerings' come as a useful corrective to English-speaking readers.

The book is excellently illustrated. There is a foreword by the Astronomer Royal, Sir Harold Spencer Jones, and an appendix dealing with the development and aims of the astronomical observatories of the world.

W. M. H. Greaves

## "INDEX GENERALIS"

**Index Generalis**

Vingt-et-unième Année, 1954–1955. (Annuaire Général des Universités et des Grandes Écoles—Académies — Archives — Bibliothèques — Instituts Scientifiques—Jardins Botaniques et Zoologiques—Musées—Observatoires—Sociétés Savantes.) Pp. xvi+2108+xx. (Paris: Dunod, 1955.) 9,500 francs.

THE "Index Generalis" first appeared in 1920 and by 1939 was a well-established work of reference, having run through a number of editions. Naturally, the Second World War seriously interrupted its publication, and it was not until 1953 that a new edition could be produced. This latest edition is based on the 1953 one with considerable corrections and additions, which make two hundred and fifty pages more of material to the already formidable total of two thousand.

The work is divided into six sections: universities and other major teaching establishments; observatories; libraries and archives; scientific institutes and research centres; academic and learned societ
and indexes. The section on universities is by
the largest, comprising more than a thousand pa
It is arranged alphabetically by countries, and wi
each country by the capital city followed by o
cities and towns in alphabetical order. (The princ
exception to this lay-out is the entry for the Un
States, where the sequence is by name of univer
institution.) For each university a list is give
professorial staff and similar persons holding se
appointments.

The section on observatories is a comparati
small one of sixty-five pages, the entries for e
observatory indicating its exact geographical posit
staff, publications, instruments and work. The
tion on libraries comprises 171 pages, sub-divide
countries. To economize in space, twenty-five c
letters, or combination of letters, are used for sp
fying particular items—for example, the numbe
books held—in the details given for each libr
The section on scientific institutes, 114 pages l
has a similar but much smaller code; but this co
not often used as the type of information given va
very much from one institute to another.
section on learned societies, which has 91 page
different from all the others in that it is grouped
subjects rather than by nations. Thus, u
"Generalités", defined as societies with more t
two subjects of study, are to be found the R
Society and the British Academy, while in a c
pletely different part of the section, under "Scie
(generalités)" are to be found the Royal Institut
the British Association and a host of other socie
such as the Royal Aeronautical Society and
Institute of Petroleum. This only serves to a
that science cannot be divided into watert
compartments, and scientific societies less
the arrangement by nations, as in all the o
sections of the book, would have been much n
preferable.

Then there are the two indexes. That dealing
names has more than a hundred thousand entries
can only be described as a 'monumental' c
pilation. Following each page reference is a num
ranging from one to eight, which indicates the
of the page in which the name is to be found;
is a great convenience, because many pages h
dozens of names scattered over them. For s
reason best known to the compilers, the lists
names beginning with *A*, *B* and *C* have short sup
mentary lists added at the end. The geograph
index, a mere thirty-four pages compared with
three hundred and fifty pages of names, is arran
alphabetically by place-names, and then under e
place are the various bodies to be found there.
main criticism to be made is that it is someti
difficult to find a particular institution, especiall
it is an American one; one has to take the var
cities in turn—New York, Chicago, etc.—and se
through the numerous entries thereunder. Fin
mention must be made of the sixty-four pages at
end of the book, on coloured paper and separa
numbered, which contain material that was sen
to the publishers after the main body of the b
had gone to press.

The whole work is primarily in French; but
should present no difficulty to the English-spea
reader with a smattering of French. In genera
can be said that in the past this book has bee
useful work of reference, and the present edi
worthily carries on that tradition.

# STRUCTURE OF VITAMIN $B_{12}$

## he Crystal Structure of the Hexacarboxylic Acid derived from $B_{12}$ and the Molecular Structure of the Vitamin

THE hexacarboxylic acid isolated from vitamin $B_{12}$ by Cannon, Johnson and Todd[1,2] has proved markably amenable to direct X-ray analysis. hrough a series of calculations of successive degrees f approximation to the correct electron density istribution, we have reached a solution of the ystal structure of this product which appears to rovide the solution also of a large part of the emical structure of vitamin $B_{12}$.

The rapid progress which we have made has een possible through the use of the National ureau of Standards western automatic comuter (SWAC) in Los Angeles, to calculate the ecessary structure factors and three-dimenonal Fourier syntheses[3]. Our general method as been to compute structure factors for all bserved X-ray reflexions based on gradually creasing groups of acceptable atomic posiions, to assign phases to the observed structure ctors after each set of calculations and to e the rephased terms to recalculate the ree-dimensional electron density distribution. his in turn was employed to revise or add tomic positions.

The starting point of the present calculaons was the recognition, described earlier[3], the first electron density maps calculated r this material (using phases based on nown cobalt atom contributions alone) of n internal nucleus surrounding the cobalt atom milar to that found in vitamin $B_{12}$ itself. Structure factors were next calculated based on 62 atoms belonging to this nucleus and to the rest of the cobalt co-ordination group. In the resulting electron density distribution there was an enormous improvement in the character of the peak pattern. In addition to the 26 atoms placed by calculation, which had peak heights from 7·5 e./A.$^{3}$ upwards, 91 independent peaks appeared with heights varying from 1·6 to 4·5 e./A.$^{3}$. All those greater than 2·5 e./A.$^{3}$, 28 in number, were in chemically reasonable sites to be assigned to atoms of side-chains attached to the main nucleus. A further ten atoms in additional side-chains were readily recognized in two following rounds of calculation. In one side-chain alone the selection of the positions of the atoms has not been straightforward and still presents certain difficulties. Since we have little doubt from other evidence of the chemical nature of these remaining atoms, we have included them with the rest of the molecule in Figs. 1 and 2, which show the most recently derived atomic positions projected on to the crystallographic a and c planes. At the latest stage of structure factor calculations based on 73 atoms in the crystal unit the agreement factor was 28·7 per cent. This figure, while it provides no guarantee that our solution is quite correct, compares not unfavourably with values often obtained for far simpler crystals built of molecules of chemically well-established structure. Interatomic distances conform with accepted values within 0·2 A., electron densities within about 1·5 e./A.$^{3}$.

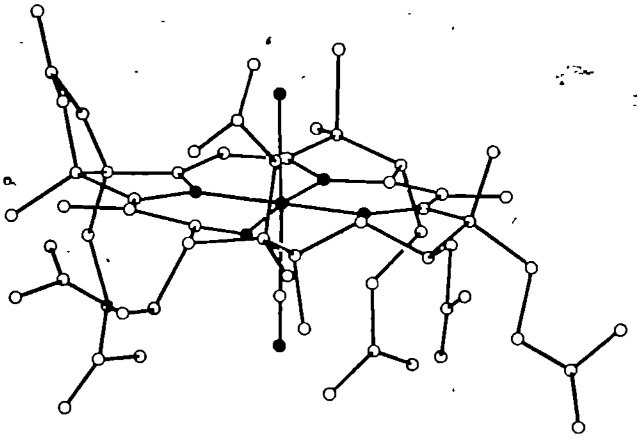

Fig. 2. Atomic positions found in the hexacarboxylic acid projected on the *c* plane. The chemical bonding deduced is outlined to emphasize the stereochemical form of the molecule

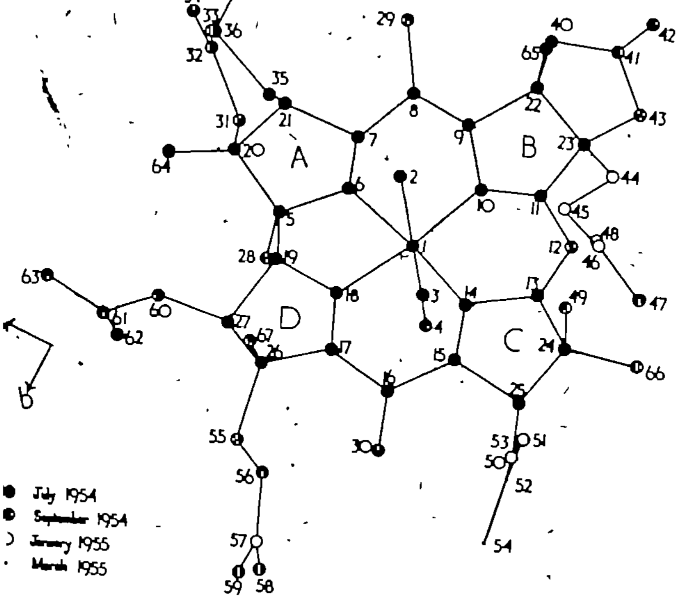

Fig. 1. Atomic positions found in the hexacarboxylic acid derived from vitamin $B_{12}$ projected on the *a* plane. The shading illustrates the course of the crystallographic study; the dates show approximately when each group of atoms was selected

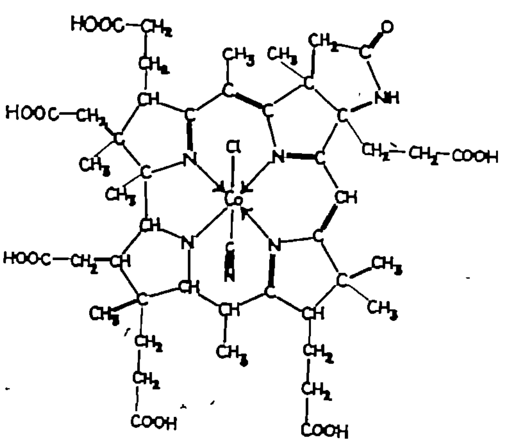
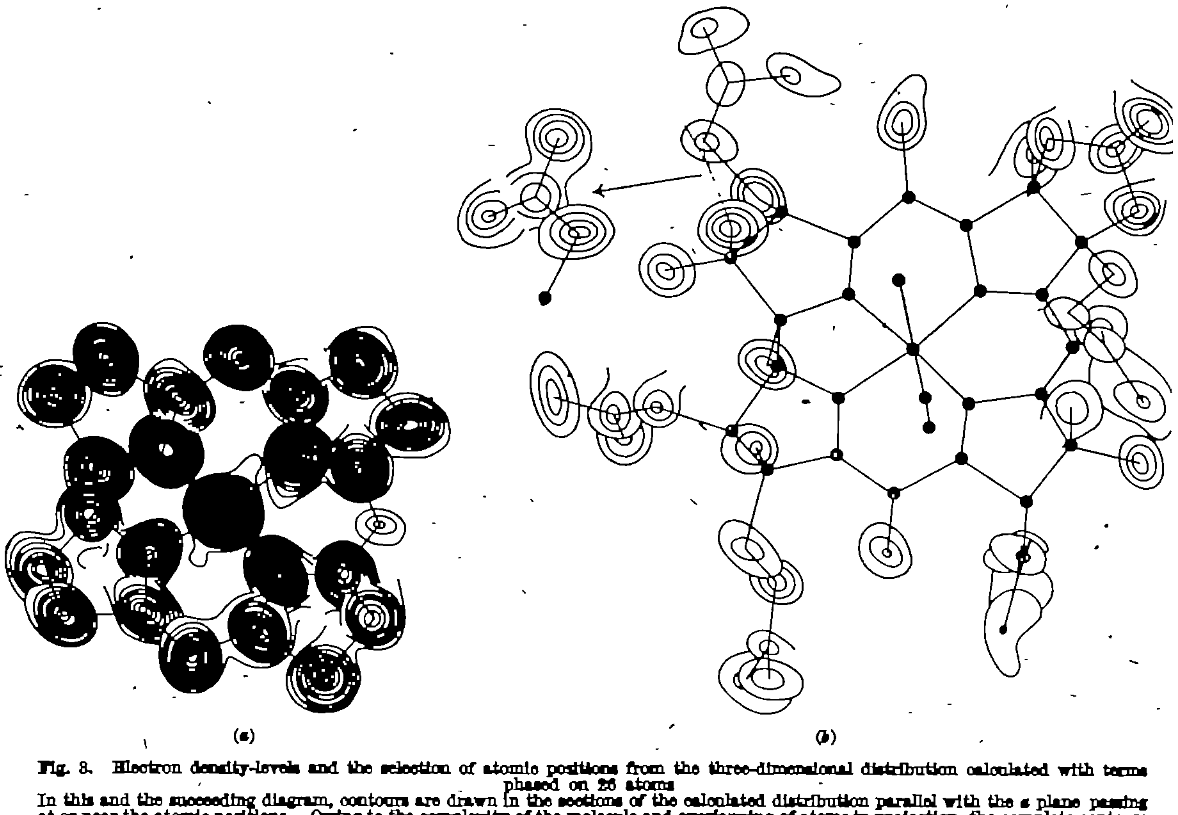
The projected atomic positions of Figs. 1 and 2 correspond with a molecule having cobalt as its centre, attached to chlorine on one side and a cyanide group on the other, and surrounded by a nucleus of 63 atoms, not counting hydrogen. Two water molecules and one acetone molecule also appear in the crystal asymmetric unit. We earlier described the inner nucleus of atoms surrounding the cobalt atom, which consists of four five-membered rings, two of which are directly linked. The geometrical form of this nucleus is now much clearer. The inner ring of atoms, from 6 to 17 in Fig. 1, lie closely in one plane, suggesting that they are linked by a system of double bonds. At the direct link *C*5 is tetrahedral and bears a single substituent atom. The outer ring of atoms, the β-positions of the five-membered rings, lie alternately above and below the plane of the inner ring. They are clearly reduced and carry substituent side-chains conforming in outline with substituted acetic and propionic acid side-chains, in the order characteristic of porphyrins of Type III, together with other single substituent atoms. All the acetic acid residues project on the same side of the ring as the chlorine atom; all the propionic acid chains on the other (Fig. 2). Even without the apparent porphyrin relationship, it would be reasonable to write the chemical nature of the atoms N, C and O in a major part of the skeleton formula I, following evidence of the geometrical distribution in space of the side-chain atoms and the relatively heavy electron density of the four inner nitrogen atoms and of many of the carboxyl oxygen atoms, as shown by Figs. 3 and 4. The chemical character of the single substituent atoms at different points on the nucleus is less certain from crystallographic evidence alone. Interatomic distances and relative weights are consistent with their all being methyl groups as suggested by the analytical evidence; but neither measurement is sufficiently precise by itself to exclude the possibility that one or other (and particularly perhaps 28 or 30) is a hydroxyl- or amino-group. The one exception is atom 43, which is combined in a ring. This atom from its electron density must be oxygen or nitrogen (as NH), the ring being either a lactone or lacta ring. Neither the position nor number of the doub bonds is certain; the system shown in formula perhaps extended by one double bond, seems mo likely; but the alternative, formula III, is also possibl



(I)

To be able to write down a chemical structure ve largely from purely crystallographic evidence on th arrangement of atoms in space—and the chemic structure of a quite formidably large molecule that—is for any crystallographer something of dream-like situation. We realize that our metho do not permit us to be dogmatic about any particul detail of our proposal formula, however much w may believe that it does as a whole correspond wit reality. Our conclusions are strengthened by chemic



(*a*) (*b*)

Fig. 3. Electron density-levels and the selection of atomic positions from the three-dimensional distribution calculated with terms phased on 26 atoms

In this and the succeeding diagram, contours are drawn in the sections of the calculated distribution parallel with the *a* plane passing at or near the atomic positions. Owing to the complexity of the molecule and overlapping of atoms in projection, the complete contours for every atom are not shown. Interval of contours, 1e./Å.³. The figures are divided into two parts to show the atoms of (*a*) the nucleus, (*b*) the side-chains. The acetic acid residue inset in Fig. 4 is viewed along the *b* axis

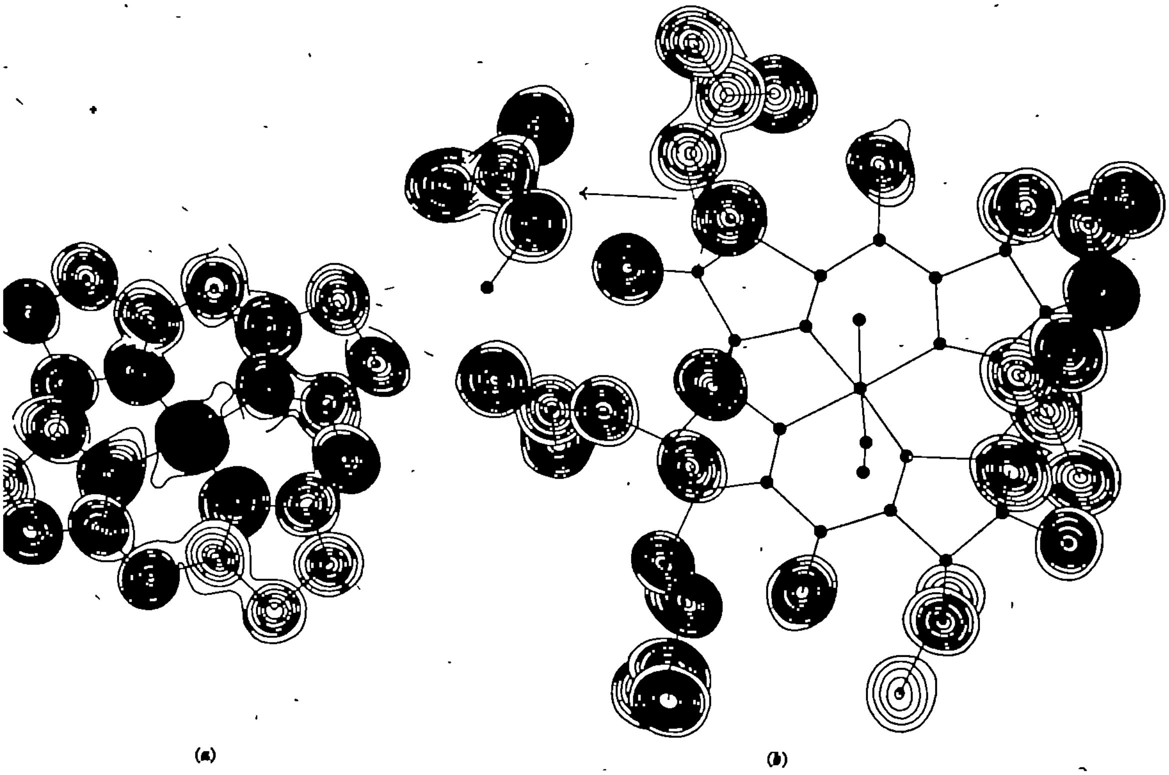


Fig. 4. Electron density-levels in the three-dimensional distribution calculated with terms phased on 68 atoms. In this and the preceding diagram it is noticeable that electron densities are usually lowest over the terminal atoms of the propionic acid side-chains owing to the greater freedom of displacement of the longer chains from their mean positions in the crystal. The effects are most marked over the side-chain on ring *C*

idence on the nature of the degradation products eady isolated from vitamin $B_{12}$[4] and discussed in tail below, and by our own parallel work on the amin itself. This additional evidence, and parularly the isolation of the succinimide, II, in the rck Laboratories[5], was most useful in deciding the ture of the only side-chain of which the atomic itions were not immediately clear from the crystal ucture of the hexacarboxylic acid.

The X-ray analysis of the different $B_{12}$ crystals is as far advanced as that of this degradation duct, and full results on these must come later. t already we have substantial confirmation for the sence of a nucleus of the above form in $B_{12}$ pro-ed that an exchange reaction has occurred in the mation of the degradation product; the nucleotide $B_{12}$ occupies the site of the CN group in the fragnt. We can also trace the positions of the atoms the propanolamine group linking the phosphate up in $B_{12}$ to the propionic acid side-chain of ring bove; only this group and the ribose molecule are ectly attached to the phosphate[6]. We can observe $B_{12}$ no evidence of an atom at the site of atom 43 the hexacarboxylic acid; instead, there is low tron density corresponding to a free acetamide up[7]. We conclude that the lactone or lactam ring ormed during degradation. These results make it possible to put forward a tentative complete structure for vitamin $B_{12}$ (III). This structure corresponds to the empirical formula $C_{63}H_{90}N_{14}O_{14}PCo$ in excellent agreement with reported analyses[7] which give figures within the limits $C_{61-64}H_{84-92}N_{14}O_{13-14}PCo$. Again, the exact number and position of the double bonds are uncertain.

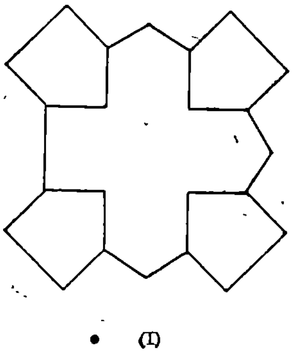
# The Structure of Vitamin $B_{12}$ and its Hexacarboxylic Acid Degradation Product

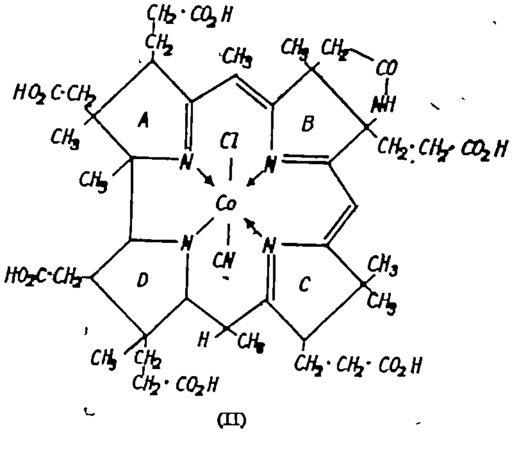
THE isolation of a crystalline nucleotide-free hexacarboxylic acid from alkaline hydrolysates of vitamin $B_{12}$ was described in an earlier communication[1], and the detailed X-ray examination of this product by our colleagues in Oxford[2] led to the recognition of the general nature of the cyclic system (I) surrounding the cobalt atom. Since that time, as described above, the relative positions of all the atoms (excluding hydrogen) in the molecule have been determined through the calculation of the full three-dimensional electron density distribution in the hexacarboxylic acid. These results, taken together with chemical evidence, have led to the proposal of the formula (II).

The crystallographic data by themselves leave open a number of details in the molecular structure of the hexacarboxylic acid, particularly the chemical nature of the single substituent atoms, the nature the ring attached to ring *B* of the nucleus, and th exact position of the double bonds in the molecul These can be partly resolved from chemical dat The sample of the hexacarboxylic acid subjected t chemical analysis was dried at 54°/0·05 mm. If is assumed that the residue still contained two mol cules of water of crystallization, then the formul $C_{46}H_{60}O_{13}N_6CoCl.2H_2O$ (C, 53·35; H, 6·2; N, 8 per cent) is in agreement with the values (C, 52·8 H, 6·3; N, 7·9 per cent) obtained from the el mentary analysis. This formula differs slightly fro that provisionally quoted in our previous com munication[1]; but the difference is clearly within th margin of experimental error. The figures ca best be accounted for by assuming that all eig single substituent atoms are present as carbon methyl groups; it seems unlikely that any of the are oxygen or nitrogen since the mode of formati of the hexacarboxylic acid (action of 30 per ce aqueous sodium hydroxide on the vitamin at 150 precludes the existence in it of any inherently unstab or labile groups. Independent evidence for t existence of ring *C* as now formulated was provid by the isolation and identification of the appropria succinimide (III), from a chromic acid oxidation a crude vitamin $B_{12}$ hydrolysate by the Merck grou and we have since obtained (III) from the chrom acid oxidation of the pure hexacarboxylic acid.

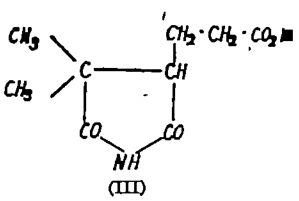
The nature of the five-membered ring attached ring *B* is the next point of ambiguity. The X-ra examination of vitamin $B_{12}$ itself reveals that t five-membered ring, which occurs fused to ring *B* the hexacarboxylic acid, is not present in the vitami which appears to contain an acetamide and a meth group as β-substituents in ring *B* and a propionami group as a β′-substituent. The extra ring in t hexacarboxylic acid is therefore produced by cycliz tion of the acetamide or acetic acid side-chain, pr sumably subsequent to hydroxylation at the remai ing β′-position, which is activated by a carbo nitrogen double bond, and the ring is therefore lactam or a lactone. The hexacarboxylic acid do not acquire an additional negative charge even high as *p*H 11, and this fact, coupled with its infr red spectrum and with the analytical figures, has l us to adopt the lactam formulation as is shown structure (II). This aspect of the problem and bearing on the structures of the tetra-, penta- a hepta-carboxylic acid degradation products[4] will discussed in detail in a later paper; but it should stressed that degradation of vitamin $B_{12}$ to a hep



(I)



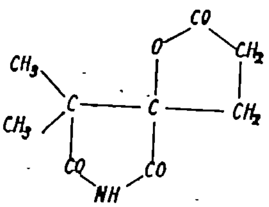
(II)



(III)

rboxylic acid without cyclization involving amide ups has only been observed in hydrolysis under d conditions.

Hydroxylation in the activated β-positions of rroline rings is well established in chlorophyll rivatives[5] and occurs with ease in the vitamin $B_{12}$ ies. When vitamin $B_{12}$ is subjected to short atment with alkali in presence of air it is con- rted into a biologically inactive crystalline sub- nce very similar to the original vitamin[6]. The idation involved in this conversion is, in our view, ring-hydroxylation of the type under discussion. support of this contention we find that the new bstance, unlike vitamin $B_{12}$, gives no heptacarb- ylic acid on acid hydrolysis, yielding instead only nixture of penta- and hexa-carboxylic acids ; on caline hydrolysis it is indistinguishable from the amin. Presumably hydroxylation will occur more dily under alkaline than acid conditions, although a hydroxyl is already present cyclization occurs der either. It may be observed that hydroxylation ring *C* can occur at least to some extent under d conditions, since the Merck group isolated the tically inactive lactone (IV) from chromic acid idations of acid hydrolysates of vitamin $B_{12}$.

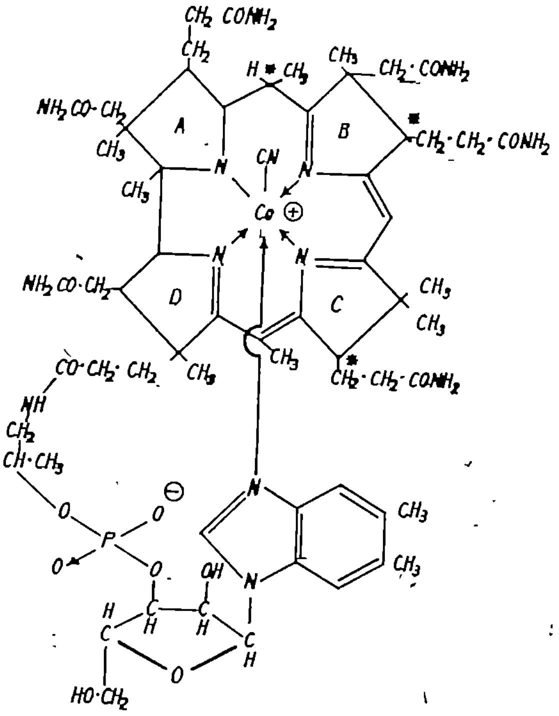


(IV)

Each of the rings *A*, *B*, *C* and *D* contains at least e tetra-substituted β-carbon atom, and conse- ently no pyrrole rings are present in the hexa- boxylic acid. It is therefore not surprising that re are many outstanding differences, both physical l chemical, between the vitamin $B_{12}$ and the phyrin series. Mention has been made elsewhere differences in the visible spectra and of the failure obtain maleimides from oxidations of the vitamin. om a vigorous hydrogen peroxide oxidation of the cacarboxylic acid (II) we have isolated oxamic d, in amounts greater than one mole per mole of amin. This observation lends support to structure ) in so far as the nitrogen of the oxamic acid must ginate in the nitrogen of the central partially uced pyrrole rings. It is of interest that, whereas mic acid has never been reported from the dation of a porphyrin, it has been isolated from dations of hydrogenated prodigiosin[7].

he conjugated double-bond system in the hexa- boxylic acid (II) was originally proposed on the unds that these constituent atoms of the macro- lic ring were effectively planar on X-ray evidence. ile there is as yet no definite chemical evidence the precise location of the conjugated system, the angement in (II) provides an adequate explanation, only for the production of (III) and of oxamic d on oxidation, but also for the behaviour of the cacarboxylic acid on chlorination, which is dis- sed below together with the chlorination of amin $B_{12}$ itself.

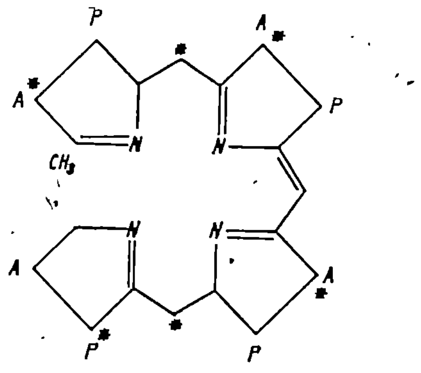
rom the X-ray studies on the hexacarboxylic acid l on the different $B_{12}$ crystals, together with con- erations of its chemical behaviour, structure (V), $H_{88}O_{14}N_{14}PCo$, is advanced for the vitamin.



(V)

According to structure (V) the vitamin contains six primary amide groups and one secondary amide joining the aminopropanol residue to the propionic acid grouping in ring *D*. It will also be observed that the vitamin is formulated as a diester of phosphoric acid, the free-acid group of the phosphate being neutralized by a positive charge on the cobalt atom. This not only accounts for the relative stability of the phosphate grouping but also for the electrophoretic behaviour of factor *B*, that is, vitamin $B_{12}$ lacking only the nucleotide, which in contrast to the parent vitamin behaves as a mono-acid base[4].

The location of the conjugated system in structure (V), although by no means proved, rests in part on the X-ray data and in part on the behaviour of the vitamin towards chlorination. On treatment of vitamin $B_{12}$ with N-chloroamides, three moles of reagent are consumed before a stable product is formed[8], and this appears to be a dichloro compound with a visible spectrum displaced into the red. Chlorination of structure (V) would be expected to result in substitution at each of the three activated positions marked with asterisks, and only one of the chlorine atoms in the product (that on the meso-carbon between rings *A* and *B*) could be eliminated as hydrogen chloride with a consequent extension of the conjugated system ; further extension of conjugation by this means is impossible. Chlorination of the hydroxylated vitamin $B_{12}$ obtained by aerial oxidation in alkaline solution consumes, as expected, only two moles of N-chloroamide with the same change in absorption spectrum. An alteration in the location of the conjugated system in passing from vitamin $B_{12}$ to the hexacarboxylic acid (II) apparently occurs, since the latter shows on chlorination the same behaviour as the vitamin—a fact most readily explained on the double-bond distribution shown in (II).



(VI)

Our confidence in structure (V) for vitamin B$_{12}$ is strengthened by biogenetic considerations. It is now widely accepted that porphobilinogen, the self-condensation product of δ-aminolævulic acid, is the precursor of many porphyrins in Nature, and indeed it yields mainly uroporphyrin III on mild acid treatment. A simple scheme for the biogenesis of the vitamin B$_{12}$ chromophore can be developed on similar lines, involving the initial formation of the tetracyclic, partially reduced, intermediate (VI; $A = CH_2COOH$, $P = CH_2CH_2COOH$). In such a molecule there are six positions (marked by asterisks) which should be susceptible to C-alkylation, and it is noteworthy that these are precisely the positions in which methyl groups occur in vitamin B$_{12}$. The ring-closure of the methylated (VI) to yield the chromophore we assume to occur by a dehydrogenation in the presence of cobalt; the appearance of a pyrrolidine ring in the final product is thus readily understood, as is also the double-bond arrangement. That rings *A* and *D* become linked directly rather than through the α-substituent of ring *A* (shown arbitrarily as methyl in (VI)) is probably due to steric considerations enforced by the non-planarity of the system. The introduction of the amide groups and the nucleotide portion as well as the necessary decarboxylation in ring *C* are regarded as secondary features.

Full details of the work described in this paper will be published elsewhere.

# JUBILEE OF RELATIVITY THEOR

## CONFERENCE AT BERNE

ALBERT EINSTEIN published his famous fir paper on relativity theory in 1905, during th time when he was employed in the Swiss Pate Office in Berne. In celebration of the jubilee of th event, a conference was held at Berne during Ju 11–16 this year. It was organized by a special con mittee of professors in the Swiss universities und the chairmanship of Prof. Wolfgang Pauli (Zuric and with Prof. André Mercier (Berne) as secretary Prof. Pauli also presided over the conference itse Almost one hundred mathematicians, astronome and physicists from some twenty different countri were present as guests of the organizing committe They included a number of official representatives national academies, who conveyed to their hosts th salutations of these academies on the occasion th was being celebrated. Among the guests were son who had made classical contributions to relativi theory in its earliest days and whose reputations we legendary to the younger visitors. It is only natur to make special mention of the revered personality Prof. Max von Laue, since he was the spontaneo choice of all the other guests as the one to expre their thanks at the final meeting. There were prese also several of those who had been associated wi Einstein in various phases of his work at Princeton.

An account of the background of the conferen has already been given in *Nature* by Prof. Mercie The scientific programme was carried through in t form originally planned before Einstein's death April of this year. The conference was official opened by Dr. Virgile Moine, directeur de l'instructi publique (Berne), and by Prof. Pauli, who recall Einstein's singular affection for the place where l early great work had been done. The subseque proceedings comprised ten principal lectures, different speakers, reviewing various departments the subject, and about twenty short papers of a mo specialized character. The committee has arrang to publish the proceedings and discussion in bo form.

A programme of this nature does not lend itself easy summarizing. However, borrowing some of t headings used by Prof. Pauli in his concludi résumé, I may record a few of my impressions.

*Observational tests of general relativity.* Doubts these matters are nowadays mainly confined to t optical tests concerning the gravitational deflexion light and the gravitational red-shift of spectral lin The difficulties in the way of making these tests e better appreciated now than when they were fi attempted. A few participants were inclined interpret the results as establishing a defin divergence from the predictions of the theory. B the majority were prepared to accept the eviden which was re-analysed and reviewed with due cauti by Dr. R. J. Trumpler, as not contradicting t theory.

*Cosmology.* Much recent evidence concerning t red-shift in the spectra of external galaxies and t distance-scale of the universe was reviewed by I W. Baade. This all tends to yield a value ab $5{\cdot}4 \times 10^9$ years for the reciprocal of 'Hubbl constant', that is, three times the value origina estimated by Hubble; but Baade considers t uncertainty in the value to be still perhaps 20 p cent. Other speakers on various aspects of cosmolo particularly Prof. H. P. Robertson and Mr. F. Hoyle, also discussed a wide range of observational results and astrophysical inferences that must be taken into account by the theory. Special reference was made to ways in which radio-astronomy may soon provide crucial information. Discussion on this level, as contrasted with abstract arguments about, say, cosmological principles, showed how cosmology has 'grown up' in recent years, as Prof. H. Bondi remarked. There was no violent conflict of views arising from theories depending upon unique or upon continuing creation of matter. Apparently the general attitude was that a verdict must await the outcome of further evidence of the kinds considered. But, indispensable as present theories are for giving direction to the work, certain of us expect that fresh concepts will sooner or later be needed.

*Mathematical methods.* Workers on relativity have gradually become aware of a number of fundamental problems involved in any mathematically adequate formulation of the subject. These are mainly boundary-value problems, topological problems and problems concerning 'global' properties of the geometries employed. It is, however, only recently that many of these problems have been given a precise formulation and solution, above all by A. Lichnerowicz[2] and his school. Prof. Lichnerowicz gave a most valuable outline of this work. Its extension to the mathematics of 'unitary' theories is in part closely related to work by Prof. P. Jordan[3], who also described his somewhat different treatment.

*Extensions of relativity theory.* General relativity is primarily a theory of gravitation. Ever since its invention, attempts have been made to extend it so as to deal with other phenomena and thereby to discover their physical relationship with gravitation. These attempts have followed one or other of two main ideas. The first is that general relativity, so far as it goes, is a 'geometrization' of physics, so that it ought to be possible to extend its physical scope by suitably generalizing the geometry employed. Einstein's own efforts to obtain a unified field-theory belong to this category; but he assigned a more profound significance[4] to them than do, probably, most other workers in this branch. The second idea is that any extension of the physical scope of relativity ought to depend upon relating gravitation to quantum-phenomena, and that an essential first step in this direction is to 'quantize' the gravitational field-equations. Both these approaches reduce in practice to making trial of formal mathematical procedures in the hope that relations will emerge which either admit significant physical interpretations or suggest the general character of the desired physical relations.

Much work along these lines was described by Prof. P. Bergmann, Dr. Harris-Kaufmann, Prof. O. Klein and others; but there seemed to be no claim that it has so far produced any advance in physical theory. While no one can assert that such exploration of mathematical possibilities will never suggest any physically interesting relationships, the majority of those present were pessimistic about the prospects.

At the conclusion of an address on relativistic invariance of quantum-mechanical equations, Prof. E. Wigner briefly and tentatively suggested a much more fundamental approach. He recalled that general relativity is based on the concept that only coincidences in space-time are observable and on the principle of equivalence. From the fact that the concept of coincidences is not applicable on the atomic scale, Wigner was led to suggest that the use of co-ordinates would have to be renounced in the basic formulation of a more comprehensive theory. From the fact that the principle of equivalence gives a priority to gravitational interaction which it does not possess in atomic systems, he suggested that the simplicity of gravitational interaction may be realized only in the later stages of such a theory. Wigner thus foreshadowed a theory that would not look at all like general relativity in its initial formulation but in which familiar relativistic features would emerge in the final development. His arguments carried considerable conviction and reinforced the doubts about the feasibility of proceeding in the opposite direction, that is, from relativity to something more general. However, Wigner did not try to formulate such a new theory, beyond offering a suggestion that its equations might involve derivatives of fields with respect to fields instead of derivatives with respect to co-ordinates.

In view of Einstein's death, there were appropriately added to the conference some features of a more personal and commemorative nature. Calling upon many recollections and intimate details of academic history, Prof. Max Born gave an illuminating account of Einstein's career and its impact upon the physics of its times. Also at the 'Jubiläumsfeier' in the University of Berne at the end of the conference, Prof. Louis Kollros (Zurich), in an address read by Prof. Mercier, gave memories of Einstein's time in Switzerland, with numerous little-known particulars.

It is remarkable that this was probably the first international conference ever to be devoted to relativity. As the foregoing notes should show, its attention was concentrated upon current, and often tentative, developments rather than upon established 'text-book' theory. The exchange of ideas that took place is certain to play a large part in future progress, and Prof. Pauli, Prof. Mercier and their colleagues have done a great service to the advancement of the subject.

# THE UNIVERSITY MUSEUM, OXFORD

By Dr. WILLIAM HOLMES

Department of Zoology and Comparative Anatomy, Oxford

THE year 1850 might formally be regarded as marking the beginning of modern science in Oxford, for it was then that there was first established a School of Natural Science, capable of conducting its own examinations, and of awarding honours degrees.

But the year 1855 marked a more substantial advance, for in that year was laid the foundation stone of the new University Museum; in this building there were, for the first time, facilities such that the teaching of undergraduates could keep pace with the growth of science.

The University Museum has always meant more to Oxford than just an establishment in which collections are maintained; it has been, from its foundation to the present day, the centre of all scientific research and teaching in the University. Before it was built, the fruits of collectors' enthusiasm had accumulated in several university buildings; as the collections grew in size they became less accessible, and more difficult to preserve. The records are probably not exact enough to reveal the extent of the losses that the collections suffered before the building of the new Museum. One disaster is, however, recorded and well known; it took place in 1755, when a decaying specimen, thought to be useless, was put on the bonfire. It was the last example of the dodo.

With the development of the Honour School of Natural Science it was found that the collections were essential for the teaching of undergraduates, and that they were ineffective for this purpose as they were, at that time, distributed. We should honour the men who realized that a change was necessary, and took steps to bring it about. In 1847 Daubeny, Duncan, Walker and Acland drew up a 'memorial' addressed to the University. They said: "We . . . being officially connected with various institutions for the advancement of Natural Knowledge in this University, are of opinion that the several collections . . . are deposited in rooms of inadequate dimension and inconvenient arrangement, and that their present efficiency and future progress are by these means retarded. . . . we are desirous of furthering such steps as may tend to the erection of an edifice within the precincts of the University for the better display of materials illustrative of the facts and laws of the Natural world".

There were some men of science in Oxford who saw no hope for the development of their subject: William Buckland, the geologist, was one of those who refused to subscribe to the memorandum which Daubeny and his colleagues had drafted; he wrote: "Some years ago I was sanguine, as you are now, as to the possibility of Natural History making some progress in Oxford, but I have long come to the conclusion that it is utterly hopeless—the idle part of the young men will do nothing, and the studious portion will throw their attention into the channel of honours and profits which can alone be gained by the staple subjects". The manuscript of this letter was to be seen among a collection of documents, many of them of the greatest rarity, arranged by Mr. H. F. Alexander in an exhibition in the Radcliffe Science Library, during the period of the recent centenary celebrations.

Many in Oxford appreciated the urgency of the situation, and the more optimistic view prevailed. In 1849 a body called the Oxford Museum Committee was set up, and appealed for subscriptions towards the cost of building a new Museum. In 1850 it told of what it had collected in a letter to members of the Convocation of the University: not a great deal had been subscribed. In 1852 a tremendous help came in the report of the Royal Commission: it recommended that the University should proceed with the plan for building a "Great Museum" and that the trustees of the collections of various kinds should be empowered to transfer their collections to this Museum.

The University proposed to act: the University Press had in its account a balance of £60,000, and it was moved that this should be transferred from the Press account to the General Account of the University. The money was to be used to cover several expenses beyond those of the Museum. It was an amusing and healthy habit, in those days, for senior members of the University to express their views in privately printed pamphlets, when they objected to proposals by the Hebdomadal Council. Such a pamphlet appeared on this occasion: "the proposed Museum, Lecture Rooms, and various other apartments, exceed greatly in number, and some in magnitude, the needful requirements. . . ."

The University established a body, called "The Delegates of the New University Museum", in 1854. The Delegates were empowered to invite architects to submit plans for a building; in December of that year Acland invited the University to a conversazione in the Radcliffe Library, to meet the delegates, and to see the fruits of this invitation. Thirty-two designs had been submitted by twenty-nine architects. The delegates had selected six as possibles, the styles of which were said to be: Italian, Jacobean, Palladian, Rhenish Gothic, Roman, and Belgian Gothic. The short list was Palladian and Rhenish Gothic.

Opposition was not silenced by the delegates' hospitality. "The Babylon of a new Museum is again before us. Have we any Students in Natural Science? No! Do we require this new Museum? No!" wrote one pamphleteer. Other attacks were on the final choice of design, which was for the Rhenish Gothic. Another pamphlet, thought to be by Acland himself, explained what was wrong with the Palladian: among many objections, he pointed out that it was of three floors, one of them in a basement, and that the laboratory and yard of the Physiological Department were placed within the mass of the building. In the Rhenish Gothic, on the other hand, the use of detached buildings around a central court allowed for expansion.

The Rhenish Gothic design, which was by B Woodward, included a great deal of decorative work for which it seems that the University was disinclined to pay. For in 1856 a circular had again to be sent round, asking for private subscriptions Shafts of different kinds of rocks were required, 124 of them at £5 each; these would be useful, as illustrations of geology; they would also be ornamental Most expensive of the items which individuals were asked to buy were the statues of the great founders and improvers of natural philosophy. These were likely to cost £70 each in Caen stone. Her Majesty the Queen had already promised several; John Ruskin, of Denmark Hill, had offered to purchase Hippocrates, Dr. Hope the statue of Linnæus, and the bachelors and undergraduates of the University Aristotle and Cuvier.

The foundation stone of the new Museum was laid on June 20, 1855, being the day of the annual Encænia; on this occasion honorary degrees were to be conferred on Tennyson and Gladstone, among others. The night before the ceremony the Chancellor of the University, Lord Derby, spoke on the subject of the new Museum at a reception in the Radcliffe Library. This is the building now known as the Radcliffe Camera, for Dr. Radcliffe's medical and scientific library was transferred to a room in the Museum as soon as it was built. A contemporary Oxford lady said[1]: "It was long and uninteresting and not delivered with spirit".

On the day of the ceremony there was lunch at All Souls, and *The Times* wrote: "After a very hurried luncheon . . . visitors proceeded . . . to the open ground known as 'The Parks'. The Old Hundredth Psalm was sung, Lord Derby laid the stone, and addressed the meeting at some length going over most of the ground which he had gone over at the Radcliffe".

On June 20, 1955, the centenary was celebrated at the same hour—by the sun's time. With equal piety but greater wit, Sir Gavin de Beer, director of the British Museum (Natural History), at the invitation of the University, gave a lecture within the walls of the Museum, to mark the occasion[2]. It was heard, with great appreciation, by the Vice-Chancellor and a large body of senior members of the University. Having surveyed the events which led to the occasion he was commemorating, Sir Gavin spoke of the growth of Oxford science in the hundred years, in the spreading group of laboratories centred on the Museum court. He named some who, working there, had made outstanding contributions: Brodie, Perkin and Sidgwick; Rolleston, Burdon Sanderson, Haldane and Sherrington; Sollas, Poulton, Geoffrey Smith, Jenkinson and Goodrich. "These masters of research set a standard of which we may justifiably be proud; and the remarkable thing is that their successors, who are fortunately still with us, have not only equalled it but surpassed it."

Looking to the future, Sir Gavin noted that the centenary by chance marks also a reorganization in the control of the collections, this change having taken place in the present year; it came about as follows.

The original building contained accommodation for seven scientific departments, as well as for Radcliffe's library. With the growth of the science faculties, new buildings were needed, and these were built at the periphery of the Museum area, on land taken from the University Parks. Since the Museum collections were useful to the teaching of science only n certain of its branches, it was inevitable that the ooms immediately adjoining the Museum court came o be reserved entirely for Departments such as those f Geology and Zoology. The collections were eniched by Dr. Hope's entomological specimens, and when, in 1861, he endowed the Hope chair of zoology entomology) the new professor moved into the building as one concerned with material which lready occupied a good deal of space. In 1883 the ethnological collection made by General Pitt-Rivers was deposited in the Museum, an annexe being built on the eastern side to accommodate it; this part of the Museum is unique, for it has its own curator. For the rest there has been no curator since 1902, and the collections have been in the care of the professors whose Departments were concerned with them. This arrangement was satisfactory so long as the professors and the members of their Departments had the time and interest necessary for them to act as 'spare-time' curators. But as the scope of science broadened, and when the time-table and the laboratories became congested, few could find time even to look after the specimens used in teaching—those which, in the Zoology Department, for example, are necessary to display the variety of animal form.

The University has this year resolved to remedy this unsatisfactory state of affairs. One member of the staff of each Department concerned with the collections has been nominated as a curator, and will serve, with representatives of the delegates of the Museum, on a committee concerned only with the collections. This committee will have the power to make independent application for funds for its work; it is to be hoped that they will be forthcoming, for much needs urgently to be done.

The new arrangement is likely to be fruitful, too, in encouraging research on the rich store of material available. In zoology, for example, it is not possible for Oxford to maintain experts on the systematics of every group of the animal kingdom. But since the appointed curator in the Zoology Department is also the lecturer in taxonomy he will be able to advise postgraduate students and visiting research workers on what can be gained from the study of the Oxford material. Also, since the most exciting progress in systematics comes now from the study of the evolutionary significance of variation, he may find, and lead others to find, new scope for experiment from the study of the material in his charge.

# NEWS and VIEWS

## ast African Agriculture and Forestry Research Organization:

### Dr. H. H. Storey, C.M.G., F.R.S

Dr. H. H. Storey has retired from the Colonial service on reaching the age limit. He joined the newly opened East African Agricultural Research nstitute at Amani, Tanganyika, as plant pathologist n 1928, after some years of service with the South African Department of Agriculture. During 1941–46 he was occupied with war supplies, and served as hairman of the East African Industrial Research Board. During this period, important work was done n the development of a phosphatic fertilizer from he extensive rock deposits at Tororo in Uganda. In 946 he was appointed secretary for Colonial agriultural research, and was closely connected with the ormation of the Colonial Research Service. In 1948 e returned to East Africa as deputy director of the East African Agriculture and Forestry Research Organization, where his administrative ability was of much value in building up this new inter-territorial venture.

Dr. Storey has made notable contributions to agricultural research and practice. He was instrumental in identifying the devastating tea 'yellows' in Nyasaland as a sulphur deficiency, and in its spectacular cure by the simple expedient of using fertilizers, for example, sulphate of ammonia, containing sulphur. His work on the interspecific hybridization of cassava to obtain virus-resistant types is probably the most extensive piece of plant-breeding yet done on a tropical food crop. More recently, his swift organization of co-operative work on breeding rust-resistant varieties of maize is likely to protect East Africa from the ravages experienced in West Africa. Dr. Storey's outstanding contribution to virus research is undoubtedly his work on the transmission processes. His original techniques for inoculating a virus into small insects, and for transferring body fluids from one insect to another, are now used by workers on both plant and animal virus diseases. It is gratifying to learn that Dr. Storey's research work will not cease on his retirement, as he has accepted a special-appointment post at the East African Agriculture and Forestry Research Organization, and pending the arrival of Dr. E. W. Russell (see *Nature*, June 18, p. 1065) he will continue as acting director.

### Dr. H. C. Pereira

DR. Pereira, who has been appointed deputy director of the East African Agriculture and Forestry Research Organization in succession to Dr. H. H. Storey, is head of the Soil Physics Department of the Organization. After completing a research on cultivation, in association with Rothamsted Experimental Station, he joined the Colonial Agricultural Service in 1946 as a member of the Kenya coffee research team. In Kenya he studied the water relationships of coffee soils with special reference to the functions of cultivation and organic mulches in maintaining the structure and permeability of the soils and, from 1949, he took an active part in co-operative work, prior to his transfer to the East African Agriculture and Forestry Research Organization in 1952. Since then he has worked on dry-farming methods applicable to East African conditions, and has paid special attention to hydrological problems in forest, arable and ranching areas. He has successfully developed soil physical methods for laboratory and field use, in tropical conditions, and has established close relations with all territorial departments concerned in hydrology.

### Applied Electricity at Bangor: Prof. M. R. Gavin, M.B.E.

DR. M. R. GAVIN, who has been appointed to the chair of applied electricity at the University College of North Wales, goes to Bangor with a valuable and varied scientific and educational experience. He graduated in mathematics and natural philosophy in the University of Glasgow in 1929, and after some years as a mathematics master in Motherwell, he joined the Research Laboratories of the General Electric Co., Ltd., in 1936. Here much of his work was concerned with high-frequency valves and circuits, which earned for him the degree of D.Sc. from Glasgow; he was also made M.B.E. in 1945 for his research work during the Second World War. In 1947 Dr. Gavin returned to educational work as H.M. Inspector in technical education with the Scottish Education Department. In 1950 he was appointed head of the Department of Physics and Mathematics in the Birmingham College of Technology, and since 1953 he has also been vice-principal. Despite difficulties, Dr. Gavin has moulded a flourishing research group in Birmingham working mainly on problems in the fields of electronics and semiconductors, and has introduced new postgraduate courses on such topics as electronics, transistors, vacuum technique, X-ray technology and gamma-radiography. The Department of Applied Electricity in Bangor is concerned with the lighter branches of electrical engineering. Although the Department is independent, the relationship with physics is a close one, since there are no other engineering departments in Bangor. Dr. Gavin's blend of experience thus fits him well for this new appointment.

### Nuclear Research and Development

UNDER the title "The Commonwealth and Nuclear Development", the Central Office of Information has produced as Reference Pamphlet No. 2 the account of the British contribution to nuclear research which the Prime Minister on June 16 promised the House of Commons would be available in time for the International Conference on the Peaceful Uses of Nuclear Energy (pp. iv+52. London: H.M.S.O. 2s. net). In five well-written chapters, to which are appended the United States proposals of March 19, 1954, for an international atomic energy agency, the United Nations draft resolution on co-operation in developing peaceful uses of atomic energy and a brief bibliography of Government publications, it gives a clear account in non-technical language of the development of nuclear physical theory to 1939 and the present position. There are also accounts of the development of nuclear weapons, the United Kingdom nuclear energy project, progress in other Commonwealth countries, particularly the Canadian programme and the position in Australia, and international co-operation in this field, leading to the European Organization for Nuclear Research, the European Atomic Energy Society and the latest agreements (June 15, 1955) between the United Kingdom and the United States.

Most of the information is summarized from officia documents; but among interesting new points the pamphlet emphasizes that an important factor in Britain's growing export of radioisotopes has been their reasonable price—and it may be noted that the price of some have been recently further reduced (see below). The average value of each of the 10,257 dispatches from Amersham last year was £20, and some useful items cost only £5. Export between October 1953 and September 1954 went to forty-one countries, and to help prospective purchasers, catalogues of radioactive materials and labelled compounds giving technical details and prices are available. Some further information i provided regarding the new experimental nuclea reactors. The zero energy fast reactor ZEPHYR which went into operation at Harwell in February 1954, will supply operating and design information of major importance for the fast breeder reacto under construction at Dounreay, while a deuterium-moderated low-energy reactor, known as DIMPLE which started operation in August 1954, has bee used for experimental work for a new and mor powerful heavy-water reactor which is being built a Harwell to provide the high-neutron flux essentia for some research purposes. This reactor, which should be operating in 1957, will be a powerfu source of radioactive isotopes as well as testin materials. The pamphlet includes Mr. Geoffre Lloyd's announcement of June 13 regarding the additional reactors to be built at Calder Hall and near Annam, and summarizes some details of industrial co-operation and of the training programme.

### Prices of British-produced Radioisotopes

REDUCTIONS in the prices of iodine-131 an colloidal gold-198, which are distributed from th Radiochemical Centre, Amersham, are announced b the United Kingdom Atomic Energy Authority. These isotopes are used extensively for treating disorders of the thyroid gland and of the lymphatic system. The concession has been made possible b a continuing growth in demand and by improve manufacturing efficiency at Amersham. The saving o the average isotope user will be about 20 per cent. Both these isotopes are in ample supply. Although hey are short lived—iodine loses half its activity in ight days and the gold loses half its activity in three days—they can be delivered by air to any part of he world at short notice; the Radiochemical Centre provides sufficient activity to compensate for that oss during transit. Among the more distant countries lready using this service are Australia, New Zealand, Argentine, Uruguay, South Africa and Japan. The new prices are: iodine-131, in carrier-free solution— minimum charge of £1 for 1 millicurie and 3s. 6d. per millicurie thereafter; iodine-131 in sterile olution—a minimum charge of £2 for 1 millicurie nd 3s. 6d. per millicurie thereafter; gold-198, in a colloidal solution—a minimum charge of £5 for 50 millicuries and 6d. per millicurie thereafter.

## Academy of Zoology, India, and *Annals of Zoology*

IN 1954 a new society, the Academy of Zoology, was founded in India, with headquarters in Agra, under the presidency of Prof. B. C. Mahendra. Its ims are to further all branches of zoology and to ncourage research, not only in India, but in countries n the East in general, with as international an appeal s possible. This is indeed an ambitious project. The Academy has started a new journal, the *Annals f Zoology*, each part of which will in general consist f a single memoir; supplements containing short otes, reviews, etc., will be issued from time to time, nd special volumes may also be issued. The first part, which appeared in January this year (1, No. 1 1955); pp. 22; Rs. 15 or 30s. for each volume of pproximately 240 pp.), is a paper by Surendra Sharmer and P. N. Tiku on the venous system of *Rana tigrina* Daud, a frog widely used in the universities of northern India, for which no detailed account f the veins is available. The paper is a straightforward piece of work carefully done and based upon he classical account in Gaupp's "Anatomie des Froches", which is a good model. The authors have ollowed Gaupp in his incorrect account of the interpretation of the relationship of the abdominal vein and hepatic portal vein. The block-making and printing are well done upon good paper, and the text s remarkably free from errors. The editor, authors nd printers are to be congratulated on a satisfactory production. Inside the cover, it is stated that the Academy intends to continue the well-known series f "Indian Zoological Memoirs" established by the late Prof. K. N. Bahl, which have come to an end with his much regretted death. This would be a valuable service to zoology and to Indian zoology in particular. Information regarding the Academy and he *Annals* can be obtained from the Secretary, Academy of Zoology, 164 Civil Lines, Agra.

## Air Pollution in Britain

THE Clean Air Bill published on July 27 is intended o implement the principal recommendations of the eport of the Beaver Committee on air pollution in Britain (London: H.M.S.O. 1s. net). It applies to Great Britain only, and four of its clauses prohibit he emission of dark smoke from chimneys, railway ngines and vessels, subject to exemption by the Minister for specified periods to cover soot-blowing, he raking of boiler fires and other necessary operations which unavoidably cause smoke for a few minutes. It will be a defence to prove that mission of dark smoke was due solely to the lighting up of a furnace from cold, an unpreventable mechanical failure, the impracticability of obtaining suitable fuel, or (for the first seven years only) the unsatisfactory nature of the furnace and the impracticability of modifying it at reasonable cost. Clause 3 prohibits the installation of new industrial furnaces unless they are capable, so far as practicable, of being operated continuously without emitting smoke. Clauses 4–7 require the emission of grit and dust from existing industrial furnaces to be minimized, and new furnaces burning pulverized coal or large amounts of other solid fuel to be provided with grit-arresting equipment. Clause 8 empowers local authorities by Order (subject to confirmation by the Minister) to designate 'smoke-control areas' in which the emission of smoke from any chimney will constitute an offence. In such areas, grants covering at least 70 per cent of the cost of adapting or replacing grates and stoves to enable smokeless fuel to be used will be payable to owners or occupiers of private dwellings, of which 40 per cent will be paid by the Government and at least 30 per cent by the local authority. The cost of these clauses to the Exchequer is not expected to exceed £3 million a year, but expenditure up to £40,000 will be incurred by the appointment of additional staff by the Ministry of Housing and Local Government and the Department of Health for Scotland.

## Forestry in Malaya

IN spite of all the troubles in Malaya, which must have made forestry working exceptionally difficult during the past few years, the *Malayan Forester* (17, No. 1; January 1955) maintains its high character. The number includes several papers presented to the Fourth World Forestry Congress held last December in Dehra Dun, India. One, on Malayan tropical rain forest, by F. H. Landon, is of exceptional interest. An important note is struck in the editorial on the housing question, which is as vital in many parts of Malaya as in Britain. In the past, the houses were built mainly of unseasoned timber and classified as 'temporary' or 'semi-permanent'. Only unseasoned wood was obtainable, and the timber trade made no effort to provide the public with seasoned wood. Now houses are built of brick and cement, tiles and metal windows, though there is an abundance of timber in the forests of the country which only requires the introduction of modern methods of seasoning to make available houses at a cheaper rate. It is scarcely a matter for surprise, then, that the Government is losing money on its forestry working.

## Evidence of Translocated Antibiotics in Expressed Plant Sap

DETAILS have been given by S. H. Crowdy and D. Pramer (*Ann. Bot.*, N.S., 19, 79; 1955) of a convenient and efficient press for extracting laboratory samples of plant sap. The pressing procedure is stated to release 53–74 per cent of the total water as expressed sap. They have also described briefly some preliminary experiments on the uptake and translocation of antibiotics. They have shown that the assay of expressed sap provides a measure of the griseofulvin and chloramphenicol concentrations in leaves of plants grown in solutions of these antibiotics, that is, in good agreement with the values obtained by the assay of water extracts. By using organic solvents, however, the authors have extracted considerably greater amounts of antibiotics than is indicated by the assay of expressed sap. To explain this difference they have postulated the existence of a 'free' antibiotic fraction, which is obtained in water extracts or in expressed sap, and a 'bound' fraction which can be recovered from the leaf only by using suitable organic solvents.

## C. L. Herrick

THE whole of a recent issue of the *Transactions of the American Philosophical Society* is devoted to an account of the astonishing life of the famous American naturalist and psychobiologist, Clarence Luther Herrick (45, Part 1; 1955). The author is his younger brother, Prof. C. J. Herrick, who writes with great pride and affection of his brother's career when holding chairs at Denison University and the Universities of Cincinnati and Chicago, his posts as United States deputy mineral surveyor and president of the University of New Mexico, and manager of the Cat Mountain Mine in New Mexico which soon became bankrupt. All this was crowded into a life of forty-six years, the last eleven of which consisted of a struggle against pulmonary tuberculosis. His brother describes him as a precocious genius "whose pioneering was in areas of remarkable diversity—in natural history surveys, in geology and paleontology, in general biology and ecology, in comparative neurology and psychology, in rare proficiency as an inspiring teacher and educational administrator, in the rejuvenation and successful reorganization of a great university, in naturalistic philosophy, and in the founding of two great scientific journals".

## Abstracts of New Zealand Scientific Papers

LAST year a new feature was started in the *New Zealand Science Review*, the official journal of the New Zealand Association of Scientists, whereby abstracts were prepared of scientific papers published in New Zealand since September 1, 1953, and, where possible, of papers published in Britain or North America which were based on work in New Zealand. By the end of the year, 502 such abstracts, covering the period up to October 30, 1954, had been printed, and in the November–December number of the *Review* (12, Nos. 11–12; 1954) are to be found author and subject indexes for all these abstracts; the subject index is particularly full and contains nearly two thousand entries. The abstracts are arranged under subject headings, and biological and agricultural subjects, as befits a country like New Zealand, greatly predominate, though entries under physical and technological subjects, etc., are to be found. It should be borne in mind, however, as a preparatory note to the subject index explains, that very little of the work in physics, chemistry or mathematics that is done in New Zealand is published in that country, and the compilers of the abstracts are fully aware that they have not covered extensively overseas journals. The onus of directing attention to their work must always rest on the authors of papers themselves.

## Ramsay Memorial Fellowships for 1955–56

RAMSAY Memorial fellowships for research in chemistry have been awarded for 1955–56 to the following: B. R. Hammond and E. Haslam, general British fellowships at the University of Cambridge; H. Inokuchi, a Japanese fellowship at the University of Nottingham; Dr. R. V. Jordana, Dr. A. Esteve and Dr. Garcia-Moliner, Spanish fellowships at the University of Cambridge; and T. Cohen, a United States fellowship at the University of Glasgow. The following fellowships have been renewed: Dr. J. A. Davies, Canadian fellowship at the University of Leeds; Dr. L. H. Ruiter, Netherlands fellowship at the University of Bristol; and Dr. C. Alfonso, Spanish fellowship at the University of Birmingham.

## Polish Medal Awards for Scientific Work

THE following medal awards have recently been made in Poland. *Biological Sciences:* Prof. J. Dembowski, for general scientific work; Prof. E. Mikulaszek, for his work entitled "Immunologically Active Polysaccharoses". *Mathematical and Physical Sciences:* Prof. K. Borsuk, for distinguished work in topology; Prof. L. Infeld, for outstanding achievements in theoretical physics and, in particular, for work on the theory of gravitation and non-linear electrodynamics; Prof. S. Pawlowski, for the discovery of sulphur deposits of great economic importance; Prof. J. Samsonowicz, for research into depth structures of the Polish Plain.

## Announcements

WE regret to announce the following deaths.—Prof. R. W. Wood, For.Mem.R.S., research professor of experimental physics in Johns Hopkins University, on August 11, aged eighty-seven; Prof. J. B. Sumner recently professor of biochemistry and director of the Enzyme Research Laboratory in Cornell University in 1946, on August 12, aged sixty-seven.

MR. SIDNEY JOHN WORSLEY, principal of the College of Estate Management, Kensington, has been appointed by the Secretary of State for the Colonies to be secretary of the Inter-University Council for Higher Education Overseas and of the Colonial University Grants Advisory Committee. Mr. Worsley succeeds Dr. Walter Adams, who has been appointed director of planning and principal-designate of the University College of Rhodesia and Nyasaland (see *Nature*, January 29, p. 193).

THE ninth General Assembly of the International Astronomical Union will be held in Dublin during August 29–September 5.

DR. N. B. CHAPMAN, senior lecturer in organic chemistry in the University of Southampton, has been appointed a reader in respect of that post.

THE College of Physicians of Philadelphia has awarded the Alvarenga Prize for 1955 to Dr. C. H. Rammelkamp for his outstanding work in the field of streptococcic infections, particularly in relation to rheumatic fever and nephritis.

THE following appointments in the University of London have been announced: Dr. Roger Warwick lecturer in anatomy in the University of Manchester to the University chair of anatomy tenable at Guy's Hospital Medical School. Dr. R. H. Gorrill, senior lecturer in bacteriology at St. Mary's Hospital Medical School, to the University readership in bacteriology tenable at Guy's Hospital Medical School.

THE ninth annual conference of the Stress Analysis Group of the Institute of Physics will be held during September 28–30 in the Stephenson Hall, University of Sheffield, and will deal with applications of stress analysis. Enrolment forms and further information can be obtained from the Secretary of the Institute, 47 Belgrave Square, London, S.W.1.

# BUILDING RESEARCH STATION, GARSTON, WATFORD

## OPEN DAYS FOR ENGINEERS

THE purpose of the display of engineering and soil mechanics work of the Building Research Station (Department of Scientific and Industrial Research) at Garston, Watford, during July 15–19, was not so much to give a general account of work in progress as to stimulate the application of the results of research by practising civil and structural engineers. To this end, special emphasis was laid on five lines of research: those concerned with reinforced concrete, steel-framed structures, load-bearing walls, bridges and foundations.

One important contribution to research was mentioned by Sir Ben Lockspeiser, secretary of the Department of Scientific and Industrial Research, in opening the exhibition. Referring to the expert advice and guidance on building research given by the Building Research Board under the chairmanship of Sir Herbert Manzoni, Sir Ben said: "This Board, consisting of people of great ability, achievement and experience in the many and varied aspects of building, give us their time voluntarily and do us a service we could not obtain in any other way. All our D.S.I.R. Stations enjoy this advantage, and it is not generally known how much scientific research owes to the public-spirited men and women who serve on our Boards".

The central theme of the presentation was that the older methods of design lead to under-estimations of the strengths of structures, that more exact methods of design are being made available, and that provision is increasingly being made, in building regulations and codes of practice, for their use.

The safety factors used in structural engineering have to take into account a number of variables, such as the mechanical properties of building materials, quality of workmanship and the knowledge of designers. On the other hand, there are many ameliorative effects, such as rigidity at joints in frames, stiffening by concrete encasing steelwork, stiffening by panel fillings, and 'composite action' generally, that cannot be taken into account until a quantitative assessment of them is possible. Display panels and testing equipment were used to illustrate the Station's work on both aspects of this general design problem.

Research on reinforced concrete has led to the inclusion in the relevant code of practice (*CP* 114) of recommendations for a new method of design—the load-factor method. The principle behind this method is that the load that will just cause failure of a structure is sufficiently greater than the working load to bring the probability of failure during the working life below a specified limit. Several exhibits illustrated research to provide data enabling designers to use the load-factor method of design with safety and economy—research on the control of quality of concrete as well as on the behaviour of walls, beams and other structural components at the point of failure.

With steel-framed buildings, three main lines of investigation are leading to more economic methods of design. Mathematical analysis has been made of a large number of idealized frames with fully rigid joints, to enable the bending moments in the neighbourhood of such joints to be assessed accurately. Secondly, an attack is being made on the problem of what happens in a steel structure when some of the steel is deformed beyond its elastic limit and passes into the plastic range. Formerly, this point was regarded as marking the limit of strength of the structure; in fact, it marks the onset of a redistribution of stresses that may result in a considerable margin of safety before actual collapse occurs. Thirdly, there is the question of how much allowance can be made for the effects of composite action, in a complete building, between the steel frame and floors and panel infillings, and between the steel members and concrete encasements provided primarily for fire protection.

A major difficulty here is that of embodying this more accurate knowledge of structural behaviour in design procedures that are not too complicated for adoption by the profession as a whole. The aim, therefore, is to express the results of mathematical analysis, once their validity has been confirmed by measurement, in simple design charts that can be used with confidence by a designer even though he may not feel at home with the analytical methods that have gone into their preparation.

The thickness of load-bearing walls has in the past been largely determined by rules-of-thumb that have been shown by experience to be safe. Such rules are often wasteful. Examples were shown of work devoted to determinations of the strength of walls under various conditions of loading, so that design recommendations on a calculated-stress basis could be formulated. The results of this work, mainly on walls and piers built with bricks and blocks, largely shaped the recommendations of the code of practice (*CP* 111) for the design of load-bearing walls—recommendations that can lead to important economies in material.

Research on bridges has naturally been pursued in close liaison with the Ministry of Transport. Perhaps the most important outcome of this work has been, in a sense, an invisible one. Throughout Great Britain there are some thousands of old bridges, carrying traffic much heavier than was envisaged at the time they were built. It was thought that many of these bridges might have to be rebuilt. The Station was asked to investigate, with the view of formulating more accurate ways of assessing the strength of such bridges. From 1936 onwards more than fifty cast-iron girder and masonry arch bridges were tested, some of them being loaded to destruction. Two important conclusions emerged: first, with the girder bridges, a load applied over one girder is partially supported by other girders; secondly, with both girder and masonry arch bridges, the fill and road-surfacing material gradually becomes consolidated and acts structurally in combination with the girders or arch so as to give a total strength considerably greater than that forecast from consideration of the basic structure alone. Many suspected bridges were thereby reprieved—a matter of immense and immediate importance when, during the Second World War, it became necessary to send heavy military vehicles up and down the country. This work on old bridges alone saved the country many millions of pounds.

Since the War, research on bridges has been concerned mainly with modern steel-and-concrete bridge decks. The most striking feature of measurements on bridges has been the low values for the strains measured in the girders, even with heavy traffic. Laboratory tests on scale-models have helped to explain this, particularly on the basis of composite action between the girders and the concrete and of the lateral distribution of load among the girders. Several possible new methods of design are being investigated, with the view of gaining all possible advantage from this structural interaction, which previously was ignored.

A working model was used in the exhibition to illustrate a series of tests that measured the dynamic effects of traffic. The impact factor (the ratio of the strain due to a load applied dynamically to that due to the same load applied statically) varied in most cases between 0·8 and 1·3, the commonest values being about unity. In the past, it has been usual to assume an impact factor of 1·5 or more for design purposes; but the tests show that such a value is unduly high and that a more economical design can be made on the safe basis of an impact factor of 1·25 or even less.

The work on bridges demonstrates *in parvo* nearly all the principles characterizing the present-day approach to the problems of designing structures above ground. Formerly the approach, in very general terms, was to reduce a structure to the simplest components that could be considered to lead an independent structural existence—joists, girders, columns, walls, slabs; the loading each component could sustain without permanent deformation was then calculated according to simple rules based on tests on such components in isolation; finally, each component was assumed to be similarly loaded in the complete structure, needing to be strong enough to support the worst probable load distribution. Any component not designed for strength was assumed to make no contribution. Nowadays, the tendency is to consider the behaviour of the complete structure, to measure stresses at critical points in buildings under construction and after completion, to account for these results by more refined theories of stress–strain pattern, and finally to interpret these theories in terms of convenient rules for design. The important thing is that investigation starts with what actually happens in actual structures.

The Building Research Station's work on foundations engineering, since it is carried on chiefly in the field, had to be demonstrated mainly by photographs. Two model-scale investigations were exhibited: in one, a glass-sided tank is used for studying the effect of seepage under hydrostatic pressure at the base of a sheet pile cofferdam; in the other, the effect is examined of proximity between piles in a group on the bearing capacity of each.

Another exhibit included part of the equipment used for measuring pore-water pressures during the construction of earth dams. Pore-water pressure tends to reduce the shear strength of the soil, with a consequent risk of instability as the height of earth fill is increased. Piezometers, incorporating a rigid porous membrane that supports the stresses due to solid material while transmitting hydrostatic pressure, are buried in the dam as work proceeds, permitting direct measurement of pore-water pressures to be made afterwards at a distance. This enables appropriate precautions to be taken if the pore-water pressure threatens to mount too high in relation to the factors contributing to stability.

# LAND USE IN BRITAIN

A CONFERENCE on "Land Use in Britain" was held in the University College of the South-West at Exeter during July 15–16. It was organized by the Division for Social and International Relations of Science of the British Association, under the chairmanship of the president of the Division, Mr. P. Ritchie Calder. The Division in this way revived its pre-war function of holding occasional meetings in different parts of the country to discuss problems in which both scientific and social questions are involved. The excellence of the prepared papers and of the discussion, and the success of the conference as a whole, fully justified this initiative.

The theme of the conference was particularly appropriate at a time when most of the local planning authorities in Britain have completed their development plans, as they were charged to do under the Town and Country Planning Act of 1947.

The first speaker was Sir George Pepler, who was chief technical adviser to the Ministry of Town and Country Planning during 1943–46 and planning adviser to the Government of Singapore during 1950–54. His theme was the administrative arrangements necessary to reconcile the demands for land for many different purposes—agriculture, housing, forestry, recreation, military training, roads, airfields, etc. Sir George emphasized that at present the framing of a national policy of land use is greatly hampered by the number of government departments involved—just as at local government level planning is hampered by the number of local committees. He urged that there should be more co-operation at both central and local government levels. As soon as possible the Minister should summarize statistically the information contained in the first batch of development plans; the summaries should be reviewed and brought up to date every five years, thus producing a periodic 'balance sheet' of the land use of Great Britain.

Mr. Geoffery Clark, planning officer for Devon, then described some of the planning problems of local authorities from his own experience. Above all, he said, it was important to "take the public with you". Plans should not be imposed from above. He had found scale-models particularly helpful in explaining planning schemes to the public.

The second session of the conference considered the need of land for agriculture and forestry. Prof. L. Dudley Stamp, professor of social geography in the University of London, discussing competing uses for land, said that while in the United States there are about thirteen acres of land, including 4–5 acres of productive land, per head of population, in Great Britain there is about 0·8 acre per head, which includes about half an acre of productive farmland. The full use of our present farmland could support a little over half our population. Some 35,000 acres a year of agricultural land would probably be needed for housing, industry and other purposes during the next twenty or so years. Industry must have first priority in an industrial nation, especially as its choice of site was often determined by natural factors such as the location of mineral workings. Housing came next, and here there was considerable controversy as to desirable housing densities. It should not be forgotten that only about a fifth of the agricultural land taken for housing remained potentially productive. Further, the quality of land used should be taken into consideration. If an acre of average and represented one 'potential production unit', then an acre of poor land would represent 0·1 unit, while one of good land would represent two units. The value of a piece of land lost to agriculture could thus vary by a factor of 20. It was therefore most mportant to ensure that the right land was used for the right purpose.

Sir James Turner, president of the National Farmers Union, then enlarged upon the importance of agriculture to the country. It was an unfortunate fact that the best farmland was very often also the most suitable for other purposes. Farming represented one-twentieth of the national income, and its output was now 153 per cent of the pre-war average, although the total labour force had decreased. Pursuing the question of the productivity of back gardens, Sir James said that while it might be true o say that garden produce was worth £66 per acre while farm produce was only worth £45 per acre, one must not lose sight of the fact that building houses meant building roads, schools, factories and shops as well. If this were taken into account, the value of garden produce averaged over the whole built-up area was about £20 per acre. What is more, gardens were not really replacing agricultural produce, and he proper comparison to make was with hortiultural holdings, which produced about £350 per acre. The land was our only irreplaceable national sset, and once built upon was lost for ever. A oherent national policy for land use which bore this n mind was urgently required.

In the discussion, Mr. F. J. Osborne, chairman of he Town and Country Planning Association, said hat increasing housing densities would not save much agricultural land. If we were to build three million houses, at fifteen houses per acre, over the next twenty years, this would use about half a million acres, or 1–1½ per cent of the remaining agriultural land of Great Britain. Increasing this density to eighteen houses per acre would not save more than 25,000 acres. To save one acre of land y building flats would cost about £20,000 in additional building costs.

The third session of the conference considered three special aspects of land use. Mr. Langley Taylor, eputy chairman of the Council for the Preservation f Rural England, said that the Cinderella of planning was amenity—not appreciated until lost; since it cannot be valued in money, it was too seldom taken into consideration. The National Parks were a step orward of great importance. Good management of orests and farmland was essential to the amenity value of the land, and here efficiency was more valuable than sentiment. We still had a long way to o before our development enhanced and did not destroy the beauty of the land.

Major L. E. Andrews from the War Office discussed he Army's needs for land for training purposes. National Service, with its greater turnover in men, modern weapons with their greater firing and manœuvring area, and modern battle training techiques had all increased the amount of land needed. About 600,000 acres of land was required for Army training; but only about 8 per cent of this land would be lost to agriculture. The Army was not n a position simply to grab land, as reports in the ress sometimes seemed to imply. The planning and agricultural authorities were always consulted, under n agreed procedure, as was the Council for the Preservation of Rural England. Usually agreement was reached; but if it was not, a public local inquiry was held, which the Army could, and sometimes did, lose.

Prof. S. H. Beaver, University College of North Staffordshire, discussed the need of land for mineral exploitation. Some 5,500 acres a year were used for this purpose at present, but by no means all of it was permanently lost to agriculture, and some of it could also be built on afterwards. Lower-value minerals like chalk, clay and gravel, which were widespread in occurrence, had to be mined where demand and transport costs made it most economic. There had been much progress recently in land reclamation methods, which meant that the sites of many old mineral workings could be built on, afforested or returned to agriculture.

During the fourth session, three papers were read to the conference on the need of land for urban and industrial development. Sir Herbert Manzoni, chairman of the Building Research Board (Department of Scientific and Industrial Research), said that production lines and mechanical handling had tended to increase the amount of space required by industry, and the majority of new factories were single-story. This trend might be reversed by developing vertical production lines and building upwards. Numerically, the population of Britain was very nearly housed, although housing is unevenly distributed; nevertheless, we already had nearly one house to three people. The real problem was the dreadful congestion of some of the urban areas. We were tending to forget the art of urban living, and in solving congestion problems we should not forget that some people like to live in towns. Current development plans would probably mean that a further half a million acres would be needed for urban development in addition to the two million acres at present occupied by housing, schools and industry. This was quite a small proportion of the total amount of land available.

Mr. P. A. Macrory, chairman of the Location of Industry Committee of the Federation of British Industries, produced three criticisms of the impact of land planning over the past three years. First, it was often far too difficult to find out exactly what the planning policy for any particular area was. Secondly, an industrialist who learns that he will be 'non-conforming' in five, ten or twenty years time often cannot discover when he will have to move, nor how much compensation he can expect. Lastly, planning control was carried down to quite unnecessary detail, and there tended to be a general negative attitude towards the industrial developer. These points all tended to get planning a bad name, but they could be remedied by more consultation and a more constructive attitude.

Prof. J. Sykes, of University College, Exeter, examined the effect planning has had on the location of industries in the past ten years. It appeared that it had so far been fairly successful in combating industrial congestion. One loophole was the fact that industrial premises vacated by non-conforming firms would be immediately filled by new firms. The local authority should supervise the change of use of premises and have the duty to offer alternatives to firms.

Summing up the conference as a whole, the chairman emphasized that this subject must be seen in relation to national and international economy. The increase in world population, and the industrialization of food-exporting countries, meant that if we wanted to import food we should only be able to do it by producing goods at a very high level of scientific and industrial achievement. In deciding the best way to divide the very limited amount of land available so that it was used to the best advantage for the whole of Britain, it was essential to know exactly what one had to divide.

This brought the conference back to the point made by Sir George Pepler at the beginning of the conference, and which came up repeatedly in discussion, namely, the need for more accurate information about how land is actually being used in Great Britain—for, as Dr. Wibberly, of Wye College, pointed out at one point, even the figures of urban acreage are in dispute.

The conference therefore concluded by agreeing to forward the following resolution to the Council of the British Association: "That the British Association for the Advancement of Science represent to Her Majesty's Government the importance of arranging for the collection and publication of comprehensive statistics of the present use of all land in this country and to prepare an analysis on a national basis of the development plans now being submitted for approval in such a way that a balance sheet of land use may be drawn up. The Association submits that the collection of this factual information is a vital need in the present stage which town and country planning has reached in this country and in the formulation of national policies of land use". JOHN DAVY

# SOCIETY FOR THE STUDY OF FERTILITY

## ANNUAL CONFERENCE

THE Society for the Study of Fertility held its annual conference during June 23–24 in the Anatomy Department of the University of Birmingham. Prof. A. M. Dalcq discussed some of the processes of synthesis occurring during the early stages of embryological development in rodents, as revealed by cytochemical studies. In the first of two stages which can be differentiated, there is a step-wise production of deoxyribonucleic acid. In the second stage, heralded by the differentiation of the embryonic knot, synthesis leads to the formation of granules rich in ribonucleic acid, which afterwards gives rise to specific proteins and the formation of enzymes. The enzymes at first are polyvalent; but later different specific enzymes appear. Embryonic development will be described more and more in terms of biochemical differentiation; at present, of course, it is possible to demonstrate this only in terms of cytochemistry. R. A. Beatty described experiments with rabbits designed to test the Russian hypotheses that heterospermic insemination (where semen from two or more donors is mixed prior to insemination) leads to specially beneficial effects among the offspring in respect of litter size and foetal weight. The results he has obtained give no support whatever to these views, and it is concluded that the litters derived from heterospermic insemination are in no way superior to those resulting from homospermic insemination.

W. R. M. Morton has studied the effects on the mating behaviour of rats caused by section of the olfactory tracts and removal of the olfactory bulbs. He concludes that complete removal of the olfactory pathways interferes with the total mating reaction but does not entirely prevent effective copulation. P. P. Scott and M. A. Lloyd-Jacob have made a study of reproduction in the domestic cat as maintained in an animal colony. It proved possible to follow the oestrous cycle by means of vaginal smears, and oestrus was found to occur at 12–14 days intervals, lasting 4–6 days. Typical oestrous behaviour was usually shown only in the presence of a tom cat, and the authors described a characteristic lateral flexion of the tail which was never observed except when oestrogens were present in significant amounts. Several consecutive matings during the period of oestrus seemed to be necessary in order to lead to conception, and the average duration of pregnancy was 65 days. A remarkable excess of males over females in the litters born was found, the ratio being 133 males per 100 females at birth.

Further studies were reported from the Anatomy Department of the University of Liverpool, under the direction of Prof. R. G. Harrison, on male reproductive physiology. E. W. MacMillan and R. G. Harrison demonstrated that the ductus epididymidis possesses an inherent peristaltic activity essential to sperm propulsion by following radiographically the passage of 50 per cent barium sulphate solution injected into the rete testis. Within four days of injection, the mass occupies a position at the junction of body and tail, and by seven days it has reached the tail loop. The vas deferens is entered on the thirteenth day, and the genital tract is completely emptied by the fourteenth day. The rate of progress is unaffected by ligation of the vasa efferentia or by ipsilateral orchidectomy. R. Harris and R. G. Harrison have investigated the effect of low temperature on the guinea pig testis. They found that little permanent damage resulted, provided the temperature within the testis did not fall below 0° C., and that freezing was more damaging than supercooling. Below that temperature occlusive spasm of the testicular artery occurred. Severe spermatogenic damage resulted from exposure of the testis to − 3° C. for one hour, but a temperature of − 10° C. was necessary to ensure an intratesticular temperature of − 4° C. when the scrotum was frozen. Severe spermatogenic destruction led to a 90 per cent fall in testicular volume.

T. D. Glover described the effects of scrotal insulation, as a means of raising the testicular temperature, on the semen of the ram. Five days elapsed before any changes in the semen appeared, and then an increased proportion of coiled tails was seen. Following this, separation of heads and tails was observed, and a marked fall in the sperm density took place about two weeks after the commencement of the scrotal insulation. Insulation for a period of only twenty-four hours led to a brief change in the semen about twenty days later, but, after a further four days, the normal semen picture was resumed.

M. W. H. Bishop discussed the inter-relationships of semen characteristics in the bull. Conception-rate was found to be most closely correlated with impedance change frequency and inversely with the percentage of dead sperms. The most significant conclusion, however, arising from his study was that a large amount of variation in fertility could not be related to any of the numerous semen characteristics examined. E. G. Bassett gave a review of investigations recently carried out at the Ruakura Animal Research Station in New Zealand on problems related to fertility in farm animals.

A number of papers on human fertility were given by workers at the Royal Free Hospital, London

Mary Barton has found a high frequency of female infertility in couples where the husband was sterile and donor artificial insemination was contemplated. The high rate of failure of such insemination in women who, by the usual standards of investigation were regarded as fertile (and for whom, of course, apparently highly fertile semen was used), was also noticeable. Sara Field-Richards and M. Moore White described the use of local œstrogen therapy for uterine hypoplasia, and Phyllis Wade reported a pregnancy in a woman who had suffered from amenorrhœa following radiotherapy for ankylosing spondylitis.

G. I. M. Swyer reported a statistical assessment of post-coital test results which confirms the diagnostic, and to a lesser extent prognostic, value of the test. The not infrequent discrepancy between post-coital test results and semen examination means that the former cannot be regarded as a redundant step in infertility investigation. Clare Harvey discussed cytological events in the human testis, as revealed by biopsies in subfertile men, in relation to abnormalities in sperm morphology. She found that a high proportion of pear-shaped heads was correlated with subfertility and that these pear-headed spermatozoa developed as a result of abnormal maturation of spermatogonia. Claude Taylor reported a conception following the insemination of centrifuged urine passed after intercourse by a man who was suffering from retrograde vesicular ejaculation. Oral treatment with potassium citrate maintained an alkaline urine in which spermatozoal activity persisted. Vigorous spermatozoal activity was found, so long as the urine *p*H was close to 7, but when either too acid or too alkaline, the spermatozoa failed to survive.

Three films were shown: one was on social behaviour in rhesus monkeys, by M. R. A. Chance; another, by H. G. Hanley, demonstrated a simplified and apparently effective technique for the operation of epididymo-vasostomy; and the third, by Prof. Richard J. Blandau, was on reproduction in the rat.

---

# INTERMETALLIC SEMICONDUCTORS

ALTHOUGH some of the earliest semiconductors of practical importance were chemical compounds, research interest in later years has been mainly in the elements germanium and silicon, partly due to the importance of transistor technology and partly because the problems of obtaining high purity and crystalline perfection appeared to be easier in a monatomic solid, and the theoretical interpretation more promising. However, with the extension of applications, new combinations of properties are desired, and it has been necessary to consider new materials—in particular, compounds, as there is little scope among the remaining elements. This trend was stimulated by the work of Welker in 1952 on compounds of the zinc-blende structure (isomorphous with germanium, but with alternate sites occupied by the respective elements). These were shown to have the high electron mobility characteristic of germanium and silicon which is essential for many applications. Still other types of compound may also have this property, so that the search has not been confined to zinc-blende types: generally, the group of compounds known as 'intermetallic' (that is, between elements having metallic properties, although the limits are not clearly defined) have shown the most interesting properties, and these are now being studied in a number of laboratories.

A study of compound semiconductors brings new problems of purification and crystal growing. The properties have then to be determined and interpreted in terms of theory, which may have to be extended or adapted in the process. Generalizations have to be attempted in order to guide further work. Finally, new applications of particular materials have to be considered. These points formed the theme of a symposium on intermetallic semiconductors which was held during April 26–27 at the Services Electronics Research Laboratory, Baldock, Herts, attended by more than a hundred and thirty visitors. The chairman for the first day was Prof. N. F. Mott (Cambridge), and for the second Prof. H. Welker (Siemens-Schuckertwerke, Erlangen, Germany). A total of nineteen papers was presented, mostly of a fundamental nature, with the emphasis on compounds of the zinc-blende type. In particular, the compound InSb, for which both the technology and theory are furthest advanced, received much attention. Arrangements have been made to publish the full papers in a special issue of the *Journal of Electronics*.

Three of the papers dealt with generalizations of a theoretical nature. Dr. F. Herman (R.C.A., Princeton), in a paper read by Dr. H. W. Leverenz, put forward a method for correlating the electronic band structure of zinc-blende type compounds with position in the periodic table of the elements concerned. In, for example, the isoelectronic sequence Ge (which may be regarded as the zinc-blende compound GeGe), GaAs, ZnSe, CuBr, the crystal potential is regarded as primarily that of germanium with a small perturbing potential due to the ionic contribution in the binding, the strength ($s$) of which increases in equal steps as we proceed along the sequence. For the regions of interest in momentum-space, the energy shifts are found to be quadratic in $s$. Measured values of the forbidden energy gap should show this same dependence, provided that no switch over occurs in the positions of the band edges in momentum-space. This latter possibility prevents outright prediction in the absence of supporting evidence, but the theory should be very useful in forming an early picture of the band structure in particular compounds of this type.

Similarly, C. H. L. Goodman (General Electric Co., Ltd., Wembley) offered a basis for the prediction of the electron mobility for a zinc-blende compound from a knowledge of the forbidden energy gap and the lattice spacing. He assumes that the covalent contribution to the binding energy and hence to the energy gap depends only on the interatomic distance ($d$) and is the same function of this as in the case of the Group IV elements. The excess of measured energy gap over that for a hypothetical Group IV element of the same spacing is regarded as an ionic contribution ($E_{\text{ion}}$). The quantity $(E_{\text{ion}}d^2)^{1/2}$ should be closely related to the bond dipole, which in turn should control the mobility, both through its influence on the effective mass, as discussed by Seraphin, and through its effect on the scattering of electrons by optical modes of lattice vibration. A plot of existing data on mobility against this parameter does give, in fact, a smooth curve, with a peak in the region of InSb, from which values for other compounds can be estimated with a fair amount of plausibility.

Still another general paper dealt with the problem of donor impurity-levels. Dr. G. Rickayzen (Services Electronics Research Laboratory, Baldock) outlined an attack on this problem in which he has examined quantum mechanically the validity of the usual hydrogen-atom model for a donor centre. He finds on certain assumptions—in particular, that the bound electron can be regarded as moving adiabatically through the lattice—that the model is justified to within an accuracy of 10 per cent, which is in rough agreement with the spread of activation energies found in practice. The accuracy should improve for structures in which the effective mass of conduction electrons is low.

Of the papers dealing specifically with InSb, the first two were concerned with photo effects. Dr. T. S. Moss (Royal Aircraft Establishment, Farnborough) gave the theory of photoconductive and photovoltaic behaviour for the case of a material like InSb which is in the intrinsic range of conduction, which has a high ratio of electron to hole mobility, and in which the rate of recombination of holes and electrons at the surfaces can be high. From photovoltaic measurements, a value of the carrier life-time can be deduced, typical values obtained for InSb being of the order of 1 μsec. Photoconductive data lead similarly to values of the surface recombination-rate; this is very dependent on surface processing, but values in the region $5 \times 10^4$–$6 \times 10^5$ cm./sec. were quoted (compare with $\sim 100$ cm./sec. in germanium). The second paper, by C. Hilsum, Dr. D. J. Oliver and Dr. G. Rickayzen (Services Electronics Research Laboratory, Baldock), dealt similarly with the photoelectromagnetic (Kikoin) effect. From this also the surface recombination velocity can be derived, the values reported agreeing with those of Dr. Moss. The method also measures life-time, for which values in the range 0·07–0·3 μsec. have been obtained.

Carrier life-time in InSb was the subject of two further papers. The first by I. M. Mackintosh (University of Nottingham) and J. W. Allen (Ericsson Telephones, Ltd., Nottingham) discussed the photon-radiative recombination process, which appears to be the dominant mechanism in this material, since it leads to the correct order of magnitude for the life-time. They showed that a theory of radiative recombination in which the probability of a transition between two levels is independent of the energies, at least over a small range, gives the correct frequency-dependence. They suggested also that InSb should be an efficient infra-red emitter. In the second paper, Drs. D. G. Avery and D. P. Jenkins (Radar Research Establishment, Malvern) described an experimental determination of the life-time by the light-spot method. Values of 0·3 μsec. were obtained at room temperature for InSb of high purity. The life-time rises with decreasing temperature, as expected from a photon-radiative process, but falls anomalously below 200° K.

V. Roberts and J. E. Quarrington (Radar Research Establishment, Malvern) described work on an accurate determination of the optical absorption in InSb over a range of temperature down to 4° K., the aim of which was to interpret in detail the electronic transition processes taking place at wave-lengths close to the absorption edge. Comparison of the results with published theoretical predictions suggests that 'indirect' transitions—that is, those in which momentum is conserved only by simultaneous emission or absorption of a phonon—are important at low levels of absorption. It is usually assumed in semiconductor work that the energy ($E$) of conduction electrons varies quadratically with their momentum ($k$); Dr. R. Barrie and J. T. Edmond (Services Electronics Research Laboratory, Baldock) showed by an analysis of thermoelectric, Hall effect and optical data that, for InSb with concentrations of electrons of $10^{18}$/c.c. or above, this approximation is not a good one. A better overall fit up to $10^{19}$/c.c. is obtained with a law of the form $E = \alpha k^2 (1 - \beta k^2)$.

Dr. B. V. Rollin and A. D. Petford (Clarendon Laboratory, Oxford) reported results of conductivity and Hall effect measurements down to a temperature of 1·5° K. on single crystals of InSb with total impurity contents in the range $10^{14}$–$10^{17}$/c.c. In $n$-type material the activation energy for conduction appears to be zero. This, they suggested, is due to overlap of bound orbitals, which will occur at lower impurity concentration in InSb, than, for example, in germanium, because of the lower effective mass. For $p$-type material an activation energy of 0·005 eV. was obtained. The carrier mobility fell off at very low temperatures, suggesting that conduction was now taking place in an impurity band. In $p$-type material at low temperatures the anomaly was found of a negative magneto-resistance coefficient. Magneto-resistance also was the subject of a paper by Dr. R. Mansfield (Bedford College, London), who had studied the behaviour of highly degenerate polycrystalline specimens of InSb. The magneto-resistance coefficient did not fall off with decreasing temperature in the manner expected from simple theory, but he felt that this would need confirmation on single crystals, since it may have its explanation in inhomogeneities associated with grain boundaries.

In a semiconductor, such as InSb, in which the ratio of effective masses of holes and electrons is appreciably different from unity, Fermi–Dirac degeneracy can occur in the intrinsic range. It is not then possible to calculate the electron and hole concentrations analytically for a known temperature and energy gap. Prof. G. Busch (Physikalisches Institut der Eidgenössen Technischen Hochschule, Zurich) discussed a simple method of doing this graphically and illustrated a slide rule based on the same principle.

A further group of papers was concerned with other compounds. Prof. H. Welker described recent work on Group III–V compounds. The energy gap in GaAs is now believed to be 1·4 eV and the ratio of electron to hole mobility to be 10 the former being estimated as 6,800 cm.$^2$/V. sec. a room temperature in the pure substance. Resistivitie as high as 100 ohm cm. have been obtained. Fo InP, the corresponding figures are 1·3 eV. and 3,300 cm.$^2$/V. sec. with resistivities up to 10 ohm cm The compound GaP is interesting in that it is transparent and of a light-golden colour. The energy ga is 2·2 eV. By mixing GaAs and GaP it is possibl to vary the energy gap continuously between the tw extremes.

Another III–V compound, InAs, was the subjec of a paper by Drs. R. M. Talley and F. Stern (U.S Naval Ordnance Laboratory, Washington, D.C. This material shows properties similar to InSb, in cluding a shift of absorption edge with increasin concentration of donor impurity. Assuming that th impurities are distributed in an ordered manne an overlap of bound orbitals will lead to an impurit band the width of which increases with concentration of impurity. The mid-point of this band will overlap the conduction band, they estimate, at a concentration of $10^{19}$ atoms/c.c. Above this concentration the material will continue to be conducting down to zero temperature, analogously to the results reported by Rollin and Petford for InSb. The lowest unfilled level available for optical transitions will increase with rising donor impurity content; on the other hand, the addition of electron acceptor impurities should empty the upper levels and therefore extend the limit of optical transitions to longer wave-lengths. This they have observed experimentally.

The compound CdTe was dealt with in a paper by Dr. F. A. Kröger and D. de Nobel (Philips Research Laboratories, Eindhoven) in which they described the preparation and properties of single crystals. Both *n*- and *p*-type crystals can be obtained by adjusting the stoichiometric balance, which can be done by heating the crystal in a suitable pressure of cadmium vapour. Thermoelectric measurements gave values for the effective masses of electrons and holes of 0·37 and 0·14 times the free mass, respectively. The corresponding mobilities were 600 and 50 cm.$^2$/V. sec. Estimates of the energy gap gave two different possible results: the value could be either 0·37 or 0·2 eV. W. S. Lawson (Radar Research Establishment, Malvern) similarly dealt with the compound $Mg_2Sn$, of which he has grown crystals of high purity. The value of the energy gap is 0·34 eV. from measurements of Hall constant, and the same result can be derived from variation of the conductivity with temperature if plausible assumptions are made about the dependence of mobility on temperature. The mobilities at room temperature are 220 for electrons and 260 cm.$^2$/V. sec. for holes.

Drs. J. van den Boomgaard, F. A. Kröger and H. J. Vink (Philips Research Laboratories, Eindhoven) gave a short paper on a technique of zone-refining a compound, such as PbS, in which one of the components, here sulphur, is volatile. The compound is sealed in a silica tube, one end of which is extended and connected to a sealed reservoir of the volatile compound. During the refining the auxiliary reservoir is kept at a temperature sufficient to give the desired vapour pressure of the volatile constituent, the remainder of the tube being kept at a rather higher temperature.

Finally, there were two papers dealing with applications. H. J. Goldsmid (General Electric Co., Ltd., Wembley) discussed the factors controlling the efficiency of a thermoelectric generator. The Fermi level (chemical potential) should lie near the edge of the appropriate band, and the mobility ($\mu$) should be large, but not due to the occurrence of a small effective mass ($m^*$); the controlling factor is $\mu(m^*)^{3/2}$, which should be large. The lattice component of thermal conductivity should be small. These requirements are most likely to be met when the mean atomic weight is large. For example, bismuth telluride (mean atomic weight 160) is particularly efficient. Using a junction of *n*- and *p*-type material, an appreciable Peltier cooling has been obtained (40 deg. C. refrigeration). The abnormally high electron mobility of InSb has led to a number of new applications, discussed in a paper by I. M. Ross and Dr. E. W. Saker (Services Electronics Research Laboratory, Baldock). The power available from the Hall effect is proportional to the square of the mobility, which gives InSb, with its electron mobility of 60,000 cm.$^2$/V. sec., a factor of ~ 300 improvement over germanium. Applications based on this feature include sensitive magnetometers, an electric compass, and a new type of power amplifier in which the input signal modulates the magnetic field in a thin crystal of the material. A new transducer principle is also possible in which the displacement to be observed causes the crystal to move in a steeply varying magnetic field. Using InSb as a resistance 'gyrator', a backward attenuation of ~ 80 db. can be obtained for a forward loss of only 7·5 db.

I. M. Ross

# LIBERAL VALUES IN FURTHER EDUCATION AND TRAINING

UNDER the title "Liberal Education in a Technical Age", the National Institute of Adult Education has published the report of a survey of the relationship of vocational and non-vocational further education and training conducted by a Committee set up early in 1953 by the Institute jointly with the Associations of Technical Institutions and of Principals of Technical Institutions, with Sir Robert Wood as chairman and Dr. P. F. R. Venables as vice-chairman. Regarding a liberal education as one which includes a training in the use of language, in the handling of ideas, in recognizing relationships, and in establishing values as touchstones for questions of taste and morals, the Committee concerned itself with the fundamental questions of the extent to which these values are affected if a study is undertaken from motives connected with personal advancement, and the extent to which they are excluded from certain studies because of their subject-matter. Attention was concentrated on the work of the technical institutions and colleges of art, correspondence courses, adult education and residential colleges, and on the role of the professional and examining bodies. Following three chapters dealing with the background of the inquiry, which include statistics relating to institutions and students, there are chapters on each of these aspects, as well as one on teachers and students in technical institutions.

Broadly, the Committee addressed itself to three questions: the extent to which technical institutions recognize any responsibility for giving their students something more than vocational instruction; if such responsibility is recognized, whether the conditions under which further education is carried on permit of anything beyond the essential technical instruction; and whether, to maintain a due balance between vocational and general education, we should look to changes in the curricula of technical institutions, or to the phasing of the whole educational process. The Committee believes that at no period in the educational process should the values commonly associated with a general education be dropped because of the intense pressure of vocational preparation, and it declined to support any suggestion that students entering technical institutions can properly embark upon a period of narrow and specialist education to the neglect of other studies. This more generous view of vocational education, it found, is held by many principals and teachers in technical institutions in spite of the gap existing between what is regarded as desirable and what is, in practice, achieved. It emphasizes that the problem can only be resolved by the pressure of public opinion and, in particular, when industry, commerce and public administration at all levels of responsibility, from higher management to supervision, share the serious concern voiced by a minority, to the extent of a readiness to extend day-time release and insist on including non-vocational as well as vocational studies.

The sharpest criticism made by the Committee is of some of the professional and examining bodies, the papers and syllabuses of which are framed to encourage the memorizing of facts rather than the discussion of underlying principles. This practice is largely responsible for the narrowness of certain technical studies, and the Committee believes that these bodies should be invited to re-assess the purpose and nature of their examinations. The Committee also comments on the unsatisfactory physical environment in which the work of technical institutions is often performed. It welcomes the recent relaxation of the utilitarian attitude of the Ministry of Education towards vocational education and hopes that local education authorities and governing bodies will now press forward with the improvement of physical conditions, including the equipment and maintenance of libraries, an increased supply of technical and non-technical books and periodicals, and the provision of adequate refectories, recreation and common rooms. The Committee believes that all education must aim at increasing human sympathy and understanding, sharpening æsthetic appreciation and giving a better command of language, and to this end it recommends that human relations in industry and commerce should be more widely studied and the æsthetic appreciation of design appropriately emphasized. It further recommends that, in technical and professional examinations at all levels, some regard should be had to the qualities derived from liberal studies, and directs attention to the value of short periods of residential education and of foreign travel. It suggests that the links between technical institutions and the responsible bodies in adult education could be strengthened with advantage to both and that the experiments being made in the university world on the reconciliation of vocational and liberal education could be profitably studied in relevance to other forms of higher education.

## INTAKE OF NUTRIENTS BY SUGAR-BEET

A STUDY of the interactions of nitrogen, phosphorus and potassium, supplied in leaf sprays or as fertilizer added to the soil, has been reported on by G. N. Thorne (*J. Exp. Bot.*, 6, 16, 20; 1955). Among findings of special interest are the following.

When sugar-beet plants grown in pots were sprayed daily with nutrient solutions supplying nitrogen, phosphorus and potassium separately or in all combinations, with precautions to prevent spray falling on the soil in which the plants were grown, all three nutrients were absorbed through the leaves. In one experiment nitrogen and potassium, and in another only nitrogen, caused increases in plant dry weight and leaf-area. Swedes absorbed phosphorus from leaf sprays and from fertilizer applied to the soil, but only the fertilizer caused an increase in dry weight.

Absorption of any of the nutrients tested from a spray containing more than one nutrient was unaffected by the presence of others in the spray; but spraying with nitrogen-containing solutions increased the absorption of phosphorus and potassium from the soil, and potassium in sprays increased the uptake of phosphorus from the soil. Nitrogenous fertilizer applied to the soil increased the leaf-area of sugar-beet plants, and hence it also increased the amounts of nitrogen, phosphorus and potassium deposited on the leaves when they were sprayed with solutions of these nutrients, and the amounts absorbed from the spray into the plants. Phosphatic fertilizer had no effect on uptake from leaf sprays. Potassic fertilizer did not affect leaf-area or the estimated volume of spray solution retained on the leaves; but it appeared to reduce uptake of potassium from the spray. Dry weight per plant was increased by all three nutrients in fertilizer, and sugar yield of the roots was increased by nitrogen and potassium in fertilizer, and by nitrogen in spray. Application of a nutrient in leaf spray reduced the responses in dry weight and sugar yield to the same nutrient applied in fertilizer to the soil.

## JUTE PRODUCTION AND RESEARCH

READERS interested in the problems of jute production in India will find a comprehensive account of relevant matters in the annual report of the Indian Central Jute Committee (for 1953–54, pp. 1–300; Calcutta) and in the annual report of the Jute Agricultural Research Institute (1953–54, pp. 1–145; 1955, Calcutta).

The primary object of this central authority is to deal with research on all aspects of jute from field to factory. The reports accordingly have sections devoted to the relevant agricultural, technological and economic aspects. At the Jute Agricultural Research Institute the programme includes jute breeding and cytogenetics, special problems of anatomy, the agronomy of jute and of crops yielding substitute fibres, and related physiological, microbiological and entomological problems. On the technological side, in addition to the normal testing, development and processing work, more fundamental researches on chemical and physical aspects have also been undertaken.

In investigations of the chemistry of the hemicelluloses of jute and other fibres it has been found that these are generally similar. Further evidence has been obtained supporting a hypothesis put forward earlier of a chemical combination between the carboxyl group of the hemicellulose and the hydroxyl group of the lignin in jute. On the physical side, the torsional rigidity of jute, ramie and sisal has been measured. It has been ascertained that heavier filaments have generally lower values for rigidity modulus and that porosity appears to be related inversely to rigidity. The elastic properties of jute filaments from plants at different stages of growth, and the effects of chemical and physical treatments on the hardness modulus of jute fibre have been investigated. Some progress in X-ray investigations of jute fibre is also reported: here the principal aim was to ascertain the size of the micelles in fibres of different quality ratios.

# THE LAMELLIBRANCH MUSCLE

## Contractile Mechanism

THE tetanic nature of muscle activity is no longer disputed except in the case of lamellibranch smooth muscle, which is supposed to maintain tension by a unique 'catch' mechanism. This postulates that viscous components within the muscle fibre should 'catch' the contractile elements and hold them at constant length in the manner of a ratchet[1,2]. I have found previously[3,4] that maintenance of tension in *intact* smooth lamellibranch adductors is accompanied by continuous electrical activity due to discharges from muscle fibres. From this it could be argued that tonus in these *intact* muscles is due to a shifting pattern of tetanic stimuli controlled by the nervous system, thus bringing it into line with tonus in other muscles and making unnecessary the hypothesis of a 'catch' mechanism.

There remained one major difficulty: if the nerves leading to the posterior adductor of ***Mytilus*** are cut, the muscle continues to maintain tension although it seems to be electrically 'silent'[3]. By using an improved recording technique I have now shown that, in fact, spontaneous electrical activity always accompanies maintenance of tension in such (externally) denervated lamellibranch muscles—a finding which strongly suggests that, even in this case, the mechanism is tetanic.

The improvement in technique mentioned above was a modification of the recording conditions. Instead of using fine electrodes recording from a very localized region[3], larger electrodes were employed in order to detect activity in a greater number of muscle units. Such electrodes consisted of 3 cm. length of 40 s.w.g. platinum wire (coated with platinum black), and they were placed around isolated muscles of eviscerated animals in air. After amplification the muscle potentials were recorded with an ink-writing oscillograph.

As recorded, the largest action potentials in muscles denervated as described above measure about 50 μV.; but in many preparations the spikes were barely visible above the noise-level of the amplifier. However, by using completely fresh animals, spontaneous action potentials have been recorded from the following (externally) denervated muscles: the wholly smooth adductors of ***Mytilus***, the smooth and spirally striated parts of the adductors of ***Anodonta*** and ***Modiolus***, the smooth part of the ***Pecten*** adductor, and from the smooth retractors of these animals.

In an earlier paper[3] I have shown that the pattern of electrical activity during tonus in the intact ***Mytilus*** adductor consists of persistent asynchronous discharges of greatly varying size, indicating continuous local activation; and of intermittent volleys of muscle potentials, evidently due to discharges from a much greater number of muscle units (Fig. 1*a*). Now in the case of all the lamellibranch muscles examined so far, there is generally less electrical activity in (externally) denervated than in intact muscles. Apart from this—in smooth adductors—the only difference is the absence of the volley response in all but the ***Mytilus*** muscle. Here volleys of a relatively shorter duration have been observed in many (but not in all) denervated preparations (cf. Fig. 1*b*). Spontaneous asynchronous discharges are also present in denervated spirally striated adductors, though their amplitude is considerably smaller than that of the discharges in the smooth muscle (Fig. 1*c*). Volleys have only been observed in very few preparations of denervated spirally striated adductors (cf. Fig. 1*c*). So far, no electrical activity has been detected in the denervated transversely striated *Pecten* adductor.

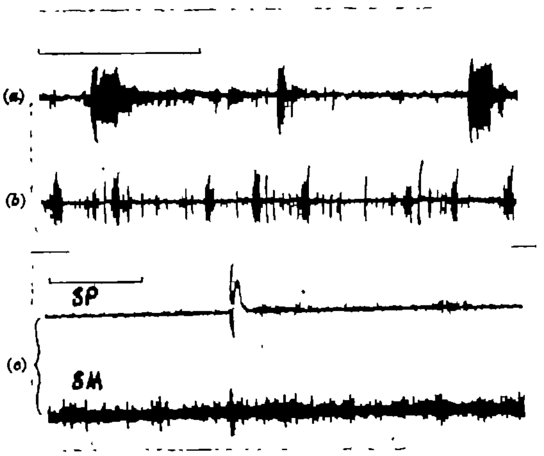

Fig. 1. The records read from left to right; time marker indicates 1 min.: *a*, ***Mytilus***, intact posterior adductor. Spontaneous electrical activity during tonic contraction; *b*, same, after (external) denervation in a preparation which showed volley responses; *c*, ***Modiolus*** (externally) denervated posterior adductor. Spontaneous electrical activity in the spirally striated (*SP*) and smooth (*SM*) parts during tonic contraction. (Note: in this preparation the spirally striated muscle showed sporadic volley responses)

The experimental evidence presented here leaves little doubt about the tetanic nature of tonus in (externally) denervated lamellibranch muscles. But how is the tetanus maintained? There are certain difficulties in the way of a myogenic explanation: only in syncytial muscle systems, like the vertebrate heart, has the self-excitatory capacity of the muscle fibres been conclusively demonstrated—and here the action potential is of the 'unitary' type. In contrast, the electrogram of lamellibranch muscle shows responses of such irregular nature and variable size that a total syncytium seems out of the question. The electrical picture is much more in keeping with the activity of numerous independent units. Of course, the units themselves could be syncytial, thus allowing for localized activity. For this, however, there is as yet no histological evidence, and in view of the very small size of the muscle fibres (2–10μ diameter) the problem is not readily tackled from the structural point of view. Considerations of size also make it difficult to look for syncytial continuities between muscle fibres with intracellular electrodes.

The recent finding of nerve-cell bodies in a variety of lamellibranch adductors and retractors[5] appears to favour a nervous origin of the spontaneous muscle-action potentials in preparations where the nerves leading to the muscle have been cut. If this be the case, then (to give both phasic and tonic responses) either the muscle fibres themselves would have to be doubly innervated or the peripheral neurones would have to be in synaptic relation with two types of motor nerve. Experiments designed to block selectively the excitatory action of possible peripheral nerve elements have so far not given conclusive results. Therefore, the question whether tonic activity in lamellibranch muscles is neurogenic or myogenic remains open.

Considering the evidence at present available, it appears that smooth and spirally striated lamellibranch muscles maintain a certain level of tension all the time due to the activity of a peripheral automatic (neurogenic or myogenic) system which works by successive activation of limited areas. Upon this spontaneously maintained tonic level, graded phasic contractions can be superimposed via a system which involves activation of large parts of the muscle and is under central nervous control[3]. Co-ordination of the numerous small muscle units is presumably made possible by the very rich nerve supply found in lamellibranch adductors and retractors[5]. An additional measure of nervous control might be provided by the action of inhibitory nerves[2]. But it has yet to be decided whether lamellibranch muscles are directly innervated by excitatory and inhibitory nerves or whether such nerves act via a peripheral ganglionic plexus.

I wish to thank Prof. B. Katz for criticism of the draft, Prof. J. J. Pritchard for much valuable discussion, and Prof. R. A. R. Gresson for his continued helpful interest. The electrical apparatus was purchased in part by a grant from the Royal Society.

## Innervation

Only two authors claim to have shown the minute innervation of lamellibranch muscle[1,2]. In 1888 Galeazzi[1] demonstrated the presence of an extremely rich intramuscular nerve plexus in the *Mytilus* adductor; but his work has hitherto been overlooked. He used the well-known formic acid–gold chloride technique to show how large nerve bundles divided and subdivided to form branches which for the most part ran parallel to the muscle fibres. From these nerves arose numerous finer branches, some of which ran towards muscle fibres, while others anastomosed freely to form a complex network. In addition to nerves, Galeazzi also reported the existence of a large number of nerve-cell bodies.

Bruch[2], using a Golgi technique, has reported the presence of motor end-plates in the spirally striated fibres of *Anodonta*. He maintained that these structures were essentially similar to those found in vertebrate skeletal muscle and differed from them mainly in being orientated at right angles to the long axes of the fibres. He was unable to obtain any nerve staining in the smooth part of the same muscle. Neither he nor a number of other workers[3-5] has made any mention of the presence of nerve-cell bodies.

In an attempt to confirm the above observations, a very large number of metallic impregnation and methylene blue techniques was tested. With the Ranvier gold chloride method it proved possible to demonstrate fine nerves, ending in bulbs, in the radial pallial muscles of *Pecten* and *Chlamys* and in the siphonal retractor muscles of *Mya arenaria*; but the results were never really satisfactory. Methylene blue was found to be excellent for tracing the course of the large nerves, but useless for showing details of innervation. With the other methods, no nerve elements could be stained. In view of the probable cholinergic nature of the lamellibranch neuromuscular system[6], histochemical methods for localizing cholinesterase were therefore tried.

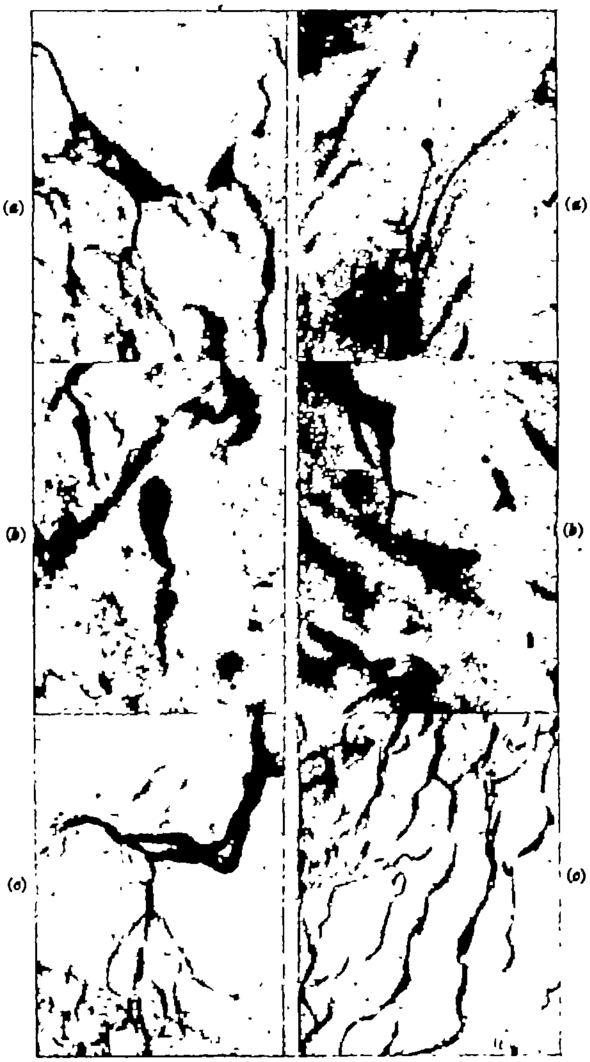

Fig. 2 Fig 3

Fig. 2. Stained by the Koelle method (× 225). *a*, Multipolar nerve-cell bodies from the anterior byssal retractor muscle of *Mytilus*; *b*, unipolar nerve-cell body from the posterior adductor of *Mytilus*; *c*, nerve trunk branching to join nerve plexus in the posterior adductor of *Mytilus*

Fig. 3. Stained by the Koelle method. *a*, Nerve endings arising from finest branches of nerve plexus in the anterior byssal retractor of *Mytilus* (× 325); *b*, nerve ending arising from nerve trunk in the posterior adductor of *Mytilus* (× 300); *c*, nerve plexus from the smooth part of the posterior *Anodonta* adductor (× 375)

With the myristoylcholine techniques[7], nerve-cell bodies can be seen in all the lamellibranch muscles so far examined; but the precipitate is too coarse to show the finer nerves. On the other hand, the Koelle method[8] gives excellent staining and reveals a nerve plexus corresponding closely to that described by Galeazzi (Fig. 2 *a*, *b* and *c*; and Fig. 3 *c*). This intrinsic nervous system is present not only in smooth adductors and retractors, but also in the spirally striated adductors. In addition, it is possible to demonstrate nerve endings with the Koelle method; but no structures like the 'motor end-plates' figured by Bruch[2] have yet been seen. Our work is still in progress and at present it is only possible to state that endings which arise from the larger nerves, as well as from the finest branches of the plexus itself, appear to terminate in bulbs (Fig. 3 *a* and *b*).

# AZETIDINE-2-CARBOXYLIC ACID : A NEW CONSTITUENT OF PLANTS

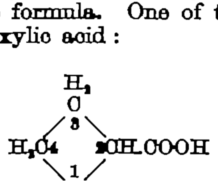
By Dr. L. FOWDEN

University College, London, and Cornell University, Ithaca, N.Y.

In recent years several new amino- and imino-acids have been encountered in plants and, in many cases, the new nitrogenous substances have constituted a large percentage of the total soluble plant nitrogen[1]. A further example has been found in *Convallaria majalis* L. (lily-of-the-valley). Two-directional paper chromatograms (phenol: butanol–acetic acid) of leaf extracts, prepared using 70 per cent ethanol, showed that the main spot was one reacting brown with ninhydrin and represented a substance not previously reported as present in plants. This new substance (hereafter termed *Z*) had an $R_F$ value of 0·80–0·84 in phenol-ammonia, and moved at a rate similar to threonine and glutamic acid in *n*-butanol-acetic acid.

By ion-exchange column chromatography ('Zeocarb' 215—0·15 *N* ammonia displacement) and subsequent paper chromatography on washed Whatman No. 3 filter paper, 250 mgm. of *Z* were isolated from 1·8 kgm. of fresh, mature *Convallaria* leaves. Three recrystallizations from 95 per cent methanol yielded *Z* as a white solid, with an elementary analysis of C, 47·6; H, 6·82; N, 13·4; O (by difference), 32·2. This approximated to the analysis calculated for $(C_4H_7NO_2)_n$, namely, C, 47·53; H, 6·93; N, 13·86; O, 31·68. Barger's method showed that the molecular weight of *Z* was approximately 100, indicating that *n* is 1 in the provisional formula.

Assuming the formula $C_4H_7NO_2$ and that the molecule contains a —COOH group and either an amino- or imino-group, the only type of open-chain compounds compatible with the formula would contain either a C=O or a C=N. *Z*, however, did not show any of the typical reactions associated with such structures, being unaffected by catalytic hydrogenation or ozonolysis. Alternatively, cyclic structures could satisfy the formula. One of the possibilities, azetidine-2-carboxylic acid :



might be expected to possess all the properties determined for *Z*. Although no account of this cyclic imino-acid appears in the literature, the parent compound, azetidine, is known, and is stable under conditions of alkaline hydrolysis, but is unstable to acid hydrolysis. Hydrolysis of azetidine with aqueous hydrochloric acid yields two products, α-amino-γ-hydroxy-propane, and α-amino-γ-chloro-propane, by ring fissure and simultaneous addition of either water or hydrochloric acid[2].

*Z* was stable to alkaline hydrolysis (5 *N* barium hydroxide solution for 24 hr. at 100°), but was completely decomposed by 6 *N* hydrochloric acid at 100° for 24 hr., yielding three ninhydrin-reactive products. The major product was always inseparable from homoserine on paper chromatograms, irrespective of the five solvents used ; the other two products first appeared as yellow spots after ninhydrin development, later changing colour through brown to a bluish-purple. These two compounds were first thought to be unsaturated since they could be converted by catalytic hydrogenation to substances inseparable from γ-amino- and α-amino-butyric acids on chromatograms ; but evidence now exists suggesting that they were α-chloro-γ-amino- and γ-chloro-α-amino-butyric acids respectively. Treatment of both compounds with concentrated ammonia solutions yielded α.γ-diamino-butyric acid. By comparison with the known mode of hydrochloric acid fissure of azetidine, the primary products of hydrochloric acid hydrolysis of *Z* are those that would be expected to arise from azetidine-2-carboxylic acid by addition of water or hydrochloric acid after splitting of the ring in either the 1 : 2 or 1 : 4 positions. The fourth possible product, α-hydroxy-γ-amino-butyric acid, has not been recognized. Extra support is available in that the nature of the products of acid hydrolysis vary with the acid used. Homoserine, as would be expected, was formed when either 3 *N* sulphuric acid, 2 *N* nitric acid or 70 per cent hydriodic acid replaced hydrochloric acid, but the additional products were characteristic of the acid used. Since hydrogen iodide is a strong reducing agent, α- and γ-amino-butyric acids appeared, together with homoserine, as direct products of ring fissure. The suggested transformations following acid hydrolysis of *Z* are outlined in the accompanying scheme (p. 348).

*Z*, like proline, gave an intense blue colour with sodium nitroprusside in 10 per cent acetaldehyde solution in the presence of sodium carbonate[3]. This test is recorded as specific for secondary amines, and, under the test conditions used, was not given by a number of α-amino-acids tested simultaneously.

The identity of *Z* as azetidine-2-carboxylic acid has been confirmed by comparison with synthetic material. This was prepared by two methods. In the first method γ-amino-butyric acid was brominated to α-bromo-γ-amino-butyric acid, which was then refluxed for 10 min. with 0·5 *N* barium hydroxide solution to remove hydrogen bromide and effect ring closure. The alternative synthesis was based on that published for proline[4]. *l*-Diamino-butyric acid monohydrochloride, kindly supplied by Wellcome Research Laboratories, Beckenham, was first converted to α-chloro-γ-amino-butyric acid, and ring closure again effected using barium hydroxide to remove hydrogen chloride. The product of the first synthesis would be the *dl*-form of azetidine-2-carboxylic acid, whereas, by comparison with the proline synthesis, optical activity could be retained with inversion of configura-

$HO.CH_2.CH_2.CH(NH_2).COOH$ homoserine
70% HI hydrolysis and reduction, 100°, 24 hr.
$H_2N.CH_2.CH_2.CH_2.COOH$ γ-amino-butyric acid
$CH_3.CH_2.CH(NH_2).COOH$ α-amino-butyric acid

tion in the second method of preparation. The samples of synthetic azetidine-2-carboxylic acid showed the same ninhydrin colour responses as *Z*, and were inseparable from it on phenol, butanol–acetic acid and collidine–lutidine chromatograms. The synthetic compounds were also cleaved on acid hydrolysis in identical ways to *Z*. Finally, the infra-red absorption spectrum of *Z* was identical with that of the synthetic material prepared from *l*-diamino-butyric acid (Fig. 1).

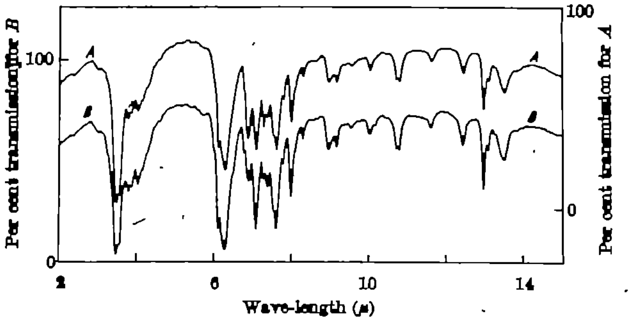

Fig. 1. Infra-red absorption spectra of nujol mulls of azetidine-2-carboxylic acid. (*A*) Isolated sample, (*B*) sample synthesized from *l*-diamino-butyric acid. Absorption peaks at wave-lengths of 3·48, 3·53, 6·86 and 7·27 μ are largely attributable to the nujol

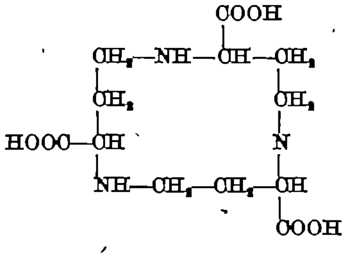
This finding of azetidine-2-carboxylic acid has extended the types of cyclic nitrogen compounds known to occur in plants, for simple four-membered ring systems based on azetidine have not previously been recorded. The existence in plants of this lower analogue of proline follows closely upon the recent discovery in plants of the higher analogue of proline, pipecolic acid.

The latter part of this work has been carried out in the laboratories of Prof. F. C. Steward, whose ready co-operation is gratefully acknowledged, during the tenure of a Rockefeller Foundation Fellowship. A fuller account of the investigation will be published elsewhere at a later date. [May 23

*Note* (June 17). Since this manuscript was prepared, an article by Prof. A. I. Virtanen and P. Linko has been published (*Acta Chem. Scand.*, 9, 551; 1955), in which the isolation of a new nitrogenous compound from *Polygonatum officinale* was described. This compound (called I), which was also stated to occur in *Convallaria majalis*, is almost certainly the same as the substance *Z* described above. All the experimental data cited for I by Virtanen, with the exception of a molecular weight determination of 303, support the idea that I is in fact azetidine-2-carboxylic acid. Virtanen, however concluded that I had the structure :



although no comparison with synthetic material was made. It would appear that this structure was dictated largely by the results of elementary analysis and molecular weight determinations.

Virtanen also described a compound (called II) which arose after hydrochloric acid hydrolysis of I and he has ascribed a complex, unorthodox formula to this compound without supporting evidence. Compound II (stated to have an elementary analysis of $C_4H_7O_2N.HCl$) would seem to be more simply explained as a chloraminobutyric acid ; II appears in fact, to have the same chromatographic properties as the α-chloro-γ-amino-butyric acid described above which gave γ-amino-butyric acid on reduction.

## Instability of the Earth's Axis

IN connexion with the theory of the instability of he earth's axis of rotation[1], it may be worth pointing ut that, besides the evidence from fossil magnetism, t is possible that independent biological confirmation ould be found of the occurrence of major latitude hanges in the past history of the earth.

However the climate may have changed in the ast, it is certain that the seasonal variation in ength of day at any particular latitude must always ave been the same; however warm the arctic winter nay have been, it was always dark. Since photoynthesis is possible only in daylight, there must lways have been a check to plant growth at high atitudes during the winter, whatever the temperaure, and this will have left its mark in the form of nnual growth rings in trees and other perennial lants. If plant fossils showing continuous growth vithout well-defined annual rings or other signs of a vinter check could be found at the present time at igher latitudes, that would be good evidence of past atitude changes, for continuous growth without an nnual winter check can never have been possible ar outside tropical latitudes.

C. B. GOODHART

niversity Museum of Zoology,
Cambridge.

Gold, T., *Nature*, 175, 526 (1955).

---

THE possibility that changes have occurred during he past in the position of the earth's axis of rotation, elative to present surface features, is of great interest o all students of fossil plants. It has long been clear hat the geological evidence of former vegetation hows that the lands around the Arctic Sea bore an mple covering of plants during a long period, probbly from Devonian to Tertiary times. This vegetaion included many large trees and was very different rom the scanty flora of those regions living to-day. rom other areas, such as South Africa, India and ustralia, there is evidence of glacial conditions ssociated with relatively small flora.

Hitherto, almost all palæobotanists of the past wenty years have accepted the hypothesis of coninental drift as being the only possible explanation f all the observed facts, in spite of the objections requently raised to this theory. The new views ummarized by Mr. T. Gold[1] will stimulate a rexamination of the palæobotanical evidence.

The use of fossil plants as tests of past climates as been under consideration for many years by many nvestigators, especially by Seward. The interpretaion of the evidence is by no means easy, since the actors of temperature, rainfall, length of day and ntensity of light are involved. The significance of rowth rings in the stems of woody plants found in petrified condition has been discussed by Gothan, nteys and others; but there is a great lack of nformation about the stems of coniferous and other lants from the older rocks of high latitudes. Wellarked growth rings were present in trees of Mesozoic ge from the arctic regions; but we should like to know whether they also occurred in trees of the same area during the Upper Devonian and Carboniferous periods. At this time the gymnospermous trees from Europe and North America showed little or no signs of a seasonal cessation of growth, whereas those from South Africa, India and Australia have very conspicuous growth rings. A specimen of petrified wood from the Antarctic Continent was described by Seward, in the report of the Scott expedition[2], as showing annual rings; but these were much less conspicuous than those in somewhat similar wood from South Africa.

There can be little doubt that the climatic changes, of which both rocks and fossils provide evidence, were of great importance in relation to the evolution of plants, and consequently to the past history of terrestrial animals. If geophysical research can establish how these changes came about, an important contribution to biology will be made.

## Reactions of Herring Larvæ to Light: a Mechanism of Vertical Migration

DURING the course of studies on the reactions of fish to light the opportunity arose for observing the behaviour of herring larvæ, *Clupea harengus* (Linn.). Initial observations were made on larvæ in shallow dishes illuminated from below by diffuse light. Each larva was dark-adapted and then observed for fifteen minutes at different light intensities, the total time spent moving in this period being recorded as a measure of its activity. The larvæ exhibited a positive photo-orthokinesis[1], their activity being proportional to the light intensity between two limits. The lower threshold for the kinesis was about 20 metre-candles, the larvæ being active for 20 per cent of the time below this intensity (down to at least 0·3 m.c.). At higher intensities, activity increased to a maximum at 4,000 m.c. when larvæ were active for 35 per cent of the total time; still higher intensities (up to 65,000 m.c.) did not increase activity further. When a light was shone at the side of the dish, larvæ swam directly towards it, showing a positive phototaxis.

Later experiments were carried out in a tall glass cylinder illuminated by diffuse light from above. Inactive larvæ sank head first weighted by their yolk-sacs; active larvæ swam directly upwards 'standing on their tails' or maintained their midwater level, swimming horizontally. Very little swimming was observed at inclinations between these planes in larvæ up to five days old at 7·5° C., although the behaviour of older larvæ became more variable. Time spent swimming horizontally, vertically, and the distance swum vertically were recorded during each observation period. The positive photo-orthokinesis persisted in this apparatus. At lower light intensities (down to 3 m.c.) and also in red light (above 6500 A.) the larvæ swam only vertically upwards when active or sank passively. After a period in the dark, larvæ were always found in midwater, so that they would appear to be active in total darkness, activity probably being at the basal

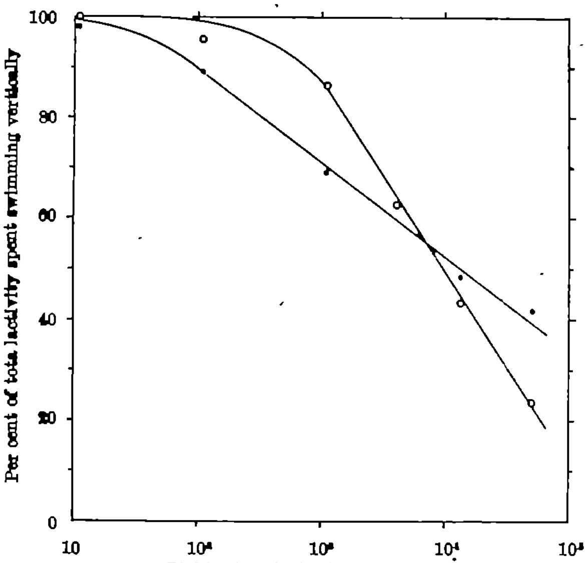

Fig. 1. Relation of change in orientation to light intensity for two typical larvæ

level observed at lower light intensities. At higher intensities (above 100 m.c.) larvæ also swam horizontally for part of the time active, this horizontal component increasing, together with the kinesis, finally increasing at the expense of the vertical component. The degree of change in orientation could be shown by expressing time spent swimming vertically as a percentage of the total time active and is directly related to the light intensity as shown (Fig. 1).

Since the change in orientation is definite, being at 90° to the light, it is assumed that the phototactic orientation is replaced by a dorsal light reaction at higher intensities. A dorsal light reaction has been demonstrated in several fish, and von Holst[2] has related the strength of this reaction to light intensity.

The reactions to light described fit the herring larva well for its environment. The larva is active in total darkness; this activity may be random, or vertically orientated as observed at lower light intensities; in the latter case it would be necessary to postulate a negative geotaxis[1] in addition to a positive phototaxis. The larva hatches from its demersal egg at low light intensities; activity directed vertically upwards either by a photo- or geo-taxis would take the larva towards the surface and higher light intensities. Once past a certain light threshold a larva will swim for a longer time and increasingly in a horizontal direction. This increase in the horizontal component will continue until the vertical component just compensates for passive sinking. Cushing[3] has suggested that the pattern of vertical migration consists of four parts; all four would be completed by the mechanism described, except that 'midnight sinking' would not occur if a negative geotaxis does indeed exist.

It is of considerable interest that such a mechanism of migration has recently been described by Harris[4] for a pond-living crustacean, *Daphnia magna*, although it would appear that the dorsal light reaction is of an all-or-none character in *D. magna*, as opposed to the finer mechanism of constant correction for sinking in the herring larva. The occurrence of similar mechanisms of depth control in planktonic animals so widely separated phylogenetically suggests that this type of behaviour may be of fairly widespread occurrence in the plankton community.

We wish to acknowledge our indebtedness to Mr. G. C. Bolster for very kindly supplying the herring larvæ.

## Rate of Milk Secretion with Increasing Interval between Milking

THE belief that the rate of milk secretion declines with time during the interval between successive milkings is based on an observed increase from thrice daily and a decrease from once daily milking over normal twice daily milkings, and on Edwards's[1] calculations of secretion-rates in milking intervals of different length. Turner[2] recently questioned Edwards's conclusions on the grounds of the regression of residual on total milk yield and suggested that the secretion-rate does not decrease until after twenty hours. On the other hand, Bailey, Clough and Dodd[3] claim to have re-established that milk secretion rate does decrease with time.

Work on the problem has been undertaken at Ruakura in view of the fact that past results have been confused by a failure to hold constant the amount of residual milk, and further by the *a priori* belief that the length of the interval preceding each experimental interval may influence the measured secretion-rate.

In these Ruakura experiments, the measurement of secretion-rate *per se* has been aimed at by removal of residual milk with 10 I.U. of 'Pitocin' and by an experimental design which also eliminated any possible effect of the preceding interval. In addition, the design has permitted the measurement of preceding interval effect.

A balanced latin square has been used, an example of which follows, the intervals used being 4, 8, 12, 16, 20 and 24 hr.:

| | Order of intervals | | | | | |
|---|---|---|---|---|---|---|
| Cows | 1 | 2 | 3 | 4 | 5 | 6 |
| 1 | 8 | 20 | 16 | 4 | 12 | 24 |
| 2 | 20 | 4 | 24 | 8 | 16 | 12 |
| 3 | 16 | 24 | 20 | 12 | 8 | 4 |
| 4 | 4 | 8 | 12 | 20 | 24 | 16 |
| 5 | 12 | 16 | 8 | 24 | 4 | 20 |
| 6 | 24 | 12 | 4 | 16 | 20 | 8 |

To eliminate preceding interval effects, 12-hr. intervals were interposed between all the experimental intervals. It should be noted that the final result of any one square represents an aggregate of six cows. The design has the disadvantage that should the feed supply or the 'Pitocin' have an undue effect on milk secretion, or should there be a carry-over effect of preceding interval through the intervening twelve-hour interval, the result of any one animal may not be considered individually.

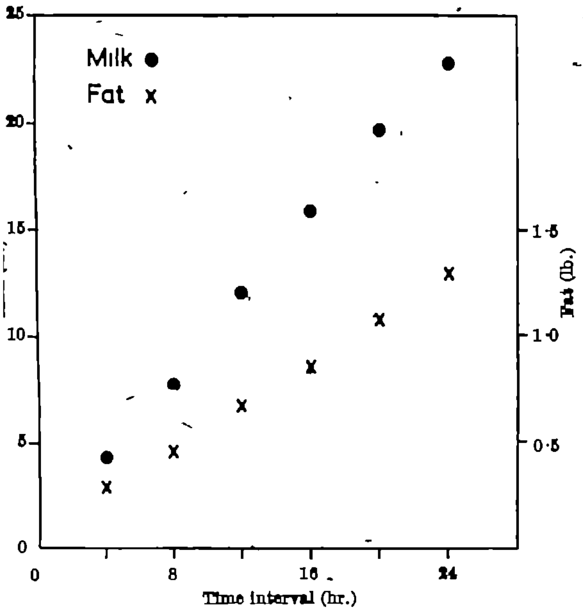

Fig. 1

Four trials have been carried out involving in each case six cows and using the design outlined above. In the first two trials the same six animals (second calvers) were used, the first being carried out when the animals averaged sixty-two days in milk, the second when 112 days in milk. The third and fourth trials involved a further twelve animals of varying ages averaging 135 days *post partum*.

Fig. 1 illustrates the type of result obtained (Trial 4). The other three experiments gave similar results. Both milk and fat secretion-rates showed no significant decline before 20–24 hr.

It is clear that up to an interval of approximately twenty hours neither milk nor fat secretion-rate decreased with increasing interval between milkings. The effect of an increase in length of the interval preceding the experimental interval was not clear-cut, but there were indications that increasing this period had a deleterious effect on rate of milk secretion and a beneficial effect on rate of fat secretion. Thus, the significant decrease obtained by Bailey *et al.* may be attributed, not to a direct pressure effect of increasing amount of milk in the udder, but to either or both of the two factors present in the Shinfield experiment and eliminated in the Ruakura experiment, namely, the effect of an increasing amount of residual milk and/or an increasing length of the preceding interval.

The significance of this conclusion in regard to the practices of milking at equal intervals and of milking three times a day is bound up with the action of these other two factors. So far as twice-daily milking is concerned, it may be suggested that unequal intervals, of a length indicated by the results of an experiment such as this, could be employed with no fear of a decrease in milk secretion due to direct pressure effects. A preliminary field trial at Ruakura using eight sets of identical twin cattle split between a 12–12 and 16–8 hourly milking regime and now in the final stages of lactation supports this contention. Similarly, observed increases with three times a day milking may not be the result of assumed reduction in udder pressure. Rather, the indications are that some other physiological function is involved. Both the Shinfield experiment and work at Ruakura indicate that such may be the case.

## Site of Phosphorus Absorption in the Sheep

THOUGH several reports[1–4] deal with phosphorus uptake by the various divisions of the gastro-intestinal tract of the sheep, they do not compare the absorption of added physiological amounts of phosphorus from normal ingesta in these organs. To satisfy this requirement sheep were allowed to graze normally until approximately four hours before being anæsthetized. The organ under investigation was then tied off and radiophosphorus, in the form of orthophosphate with 1 mgm. per mc. carrier, injected into it. Blood samples were taken, at intervals, from the left jugular vein, and the plasma assayed for radioactivity in a dipping counter.

The graph (Fig. 1) shows the level of plasma activity, measured in μc./ml. per unit dose, plotted against time. The term unit dose refers to a dose of 66·7 μc. per litre of organ volume. This gives a rumen dose of 1 mc. Doses were calculated from organ volumes taken from Sisson[5].

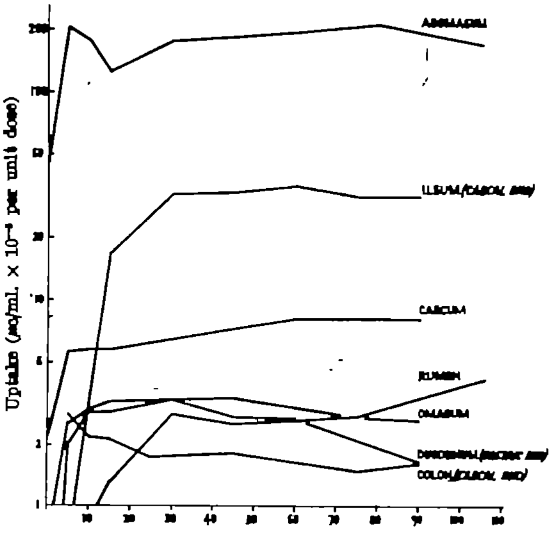

Fig. 1

The curves show that the absorption by the rumen, omasum, duodenum, colon and the cæcum are of the same order of magnitude. The apparently higher value for the cæcum is not considered significant. By contrast, absorption by the ileum is of an order ten times, and that by the abomasum one hundred times, greater.

The similarity of the figures for organs other than the ileum and abomasum suggests that the mechanism involved is one of simple exchange as distinct from true absorption by the latter.

The suggestion by Pathasarathy[6] that absorption occurs from the omasum is not supported by these figures.

This work is continuing and will be reported in full elsewhere.

## Plant Growth on 'Fly Ash'

THE difficulties of the satisfactory disposal of the pulverized fuel waste from power station boilers, often referred to as fly ash, is world wide. In Britain the problem is particularly acute, especially where agricultural land is used for its disposal[1]. The present findings are the result of an intensive study of crop problems which are likely to be encountered when attempts are made to revegetate areas of agricultural importance which have become contaminated with this waste product.

Preliminary field-observation had suggested that the ash might contain certain substances which seriously retard the growth of plants. Indeed, the common weeds which rapidly establish themselves on other industrial wastes seem unable to colonize this material with probably three exceptions, the most successful being the chenopodiaceous plant *Atriplex hastata* var. *deltoidea* (hastate orache). This plant quickly forms practically pure stands on the bare ash when other weeds and rough grasses are completely excluded. It seems, therefore, that the properties of the ash which seriously affect the normal physiology of most plants are resisted by *Atriplex*. These circumstances would appear to afford an opportunity for further contributions to our knowledge of the physiology and autecology of ruderal plants, and at the same time to produce valuable information on the plant/ash nutrient relationships.

Chemical analyses of the main constituents of the fly ash are periodically published by the Central Electricity Authority; but as yet no attempt seems to have been made to examine its plant nutrient properties as compared with those of a normal soil. Detailed spectrographic analysis of the ash and a typical soil, kindly made for us by the Macaulay Institute, together with our own exhaustive analytical studies, indicate that aluminium, manganese, iron and nickel only are present in quantities toxic to plants. Other potential toxins present, for example, zinc, cobalt, chromium and titanium, at first suspected, in all probability exist in harmless quantities. Of the major plant nutrients, nitrogen alone appears deficient, forming some 0·04 per cent of the oven-dried ash.

Sand culture experiments with barley using the following levels of toxic metals: aluminium, 3 meq., manganese, 3 meq., nickel, 1 meq., and iron, 1 meq., in one litre of ordinary culture solution, singly and in all combinations, produced the following symptoms:

Aluminium: stunting, lack of tillering; purplish tint on stems; erect pointed leaves with brown brittle tips and die back

Manganese: slight stunting; leaves with brown tips and die back and dark brown spotting on the lamina later coalescing as brown streaks.

Nickel: plants severely stunted and chlorotic; leaves with white necrotic areas beginning in the middle of the leaf and causing its collapse.

Iron: Slight purplish tint, otherwise growth as per control.

Metals in combinations produced additive symptoms.

Barley grown on ash to which a full culture solution had been added developed symptoms identical with those produced in the sand culture which contained manganese and aluminium. No nickel symptoms were produced. On the other hand, *Atriplex* grew normally in sand culture containing aluminium, manganese and iron at toxic levels, but was severely stunted and chlorotic when nickel was added.

In another series of culture experiments, a number of crop plants were grown in an ash/culture medium. The plants selected have been shown by Hewitt[2] to be sensitive indicators of toxic levels of aluminium and manganese alone or in combination. In all cases the ash induced symptoms comparable to those described by Hewitt. These findings were confirmed by tissue analyses. Plants grown on ash always showed an excess uptake of manganese and aluminium as compared with the controls.

Water-culture experiments using different levels of nitrogen have shown that *Atriplex*, in contrast to crop plants, can tolerate low levels of nitrogen without effect on its normal growth.

We thank Dr. E. J. Hewitt, of Long Ashton, for his help, and the Central Electricity Authority for providing facilities for field-studies. A fuller account will be published elsewhere.

## Œstrus in Zebu Cattle in Uganda

DURING investigations into the possibility of artificial insemination of indigenous Zebu and Nganda cattle with homologous semen obtained by electrical stimulation, the œstrous cycles of an experimental group of heifers have been determined, using marked vasectomized bulls. The animals have been examined for evidence of service at 0700 and 1900 hr. local time. In two months, œstrus has been detected in five animals on fifteen occasions; but marking by the bull has never occurred on less than two occasions. These were recorded as of 12 hours duration (0700–1900 hr., and vice versa). Based on this marking of the females, three heat periods lasted 12 hr., nine lasted 24 hr., two lasted 36 hr. and one lasted 48 hr. Of this total, six (40 per cent) were first recorded at 0700 hr. (commenced during darkness), and nine were first recorded at 1900 hr. (commenced during daylight).

More recently, during observations of the habits of Zebu cattle[1], two cows have been observed in detail throughout œstrus, and these observations have helped to explain the above results. Our observations show that the cows are attractive to the bull for some hours before and after they are ready to accept service. Thus in one instance the bull detected the ow 4 hr. 33 min. before she would accept service, nd during the last 1 hr. 44 min. of this period, xteen attempts to serve were made. One service nly was allowed; but the bull's interest continued r a further 9 hr. 37 min. In the second instance, he bull detected the cow 10 hr. 24 min. before ervice was allowed. The cow then permitted service wice in 16 min., and the bull continued to attempt ervice for a further six hours; in fact, serving the ow once again 2 hr. 12 min. after the preceding ervices, when the cow was no longer truly receptive.

These results are of interest, for they agree with eld-observations that African cattle owners may uccessfully walk cows several miles 'to the bull', ut differ from previous scientific work in some espects. The observations suggest that while the uration of œstrus is short in the Zebu at Entebbe, he period of pro-œstrus is much longer than the 4–63 min. reported in Kenya[2], the behaviour of the emale remaining at stage 1 and 2 of œstrus[3] for a onsiderable period before and after œstrus. These esults are more in agreement with South African orkers[4], who found the mean duration of onset of estrus in indigenous Afrikander cows to be 7·46 hr. range 0–24 hr.), and the average time of the disppearance of œstrus 5·73 hr. (range 0–18 hr.).

The proportion of animals coming into œstrus uring darkness (40 per cent) is very similar to that eported in Kenya[2] (31·3 per cent, allowing one-third or 1 hr. difference between 0600 and 0700 hr. within he period of observation, 0600–0900 hr.). It has een reported that at the Messina Experiment tation in South Africa[5], 90 per cent of œstrus commenced between midnight and 0900 hr. This compares with 45·3 per cent in Kenya[2] for the identical ime. On the other hand, in Sweden[6] it has been eported that 43 per cent of œstrus commenced during aylight and 57 per cent during darkness.

The duration of œstrus in the above two observaions is very similar to that reported from Kenya[2,7] nd shorter than that reported for South Africa[4] 7·88 hr., range 1–14 hr., indigenous Afrikander), or the Philippines[8], where a mean of 13·3 hr. (range ·5–22·4 hr.) was recorded for native cattle.

There are marked climatic differences between ntebbe and the sites of the stations where the bservations referred to above were made. The limate at Entebbe (altitude 3,780 ft.) is very equable, ith a well-distributed rainfall (average 59 in.), and umidity frequently high due to the proximity of ake Victoria[9]. The latitude of 0° 02′ N. gives little ariation in length of daylight.

It is hoped to extend and report these findings in rther detail at a later date.

## Reaction to Light of Iris-Chromatophores

FIELD workroom observations in this Sanctuary show that intensity of daylight controls reaction of chromatophore cells in irises of the male duck *Netta erythropthalma* (Wied.). A minor field characteristic of the male African pochard is the brilliant vermilion iris—a feature easily discernible with binoculars at up to about a hundred yards. The female's irises are umber.

Timed observation revealed, on taking the male from a lightproof box in a daylit workroom to the window:

| | |
|---|---|
| 0 min. | Irises dull yellow ochre |
| 1 ,, | First suggestion of red suffused: no noticeable pattern |
| 2·5 ,, | Irises much warmer and darker |
| 3 ,, | Red area extends; grows stronger |
| 4 ,, | Irises nearly all red |
| 5 ,, | Irises 'normal'. Brilliant vermilion suffused over dull ochre background |

The radical reaction of chromatophores occurs simultaneously in various parts of the iris. When colour-change is apparently complete there remain pinpoints of ochre. The action commences before pupils have completely contracted.

Further field-work is in progress, and laboratory examination of the eyes will be carried out. Other members of Anatidae are being subjected to examination.

## Two New Mutations in the Syrian Hamster

THE Syrian hamster, *Mesocricetus auratus*, introduced to the laboratory by Adler and Theodor[1] in 1931, is a golden-brown rodent with pale cream belly fur and two characteristic throat flashes. Melanic pigment darkens the skin of the ears and is present about the genitals in both sexes (in the region of the vulva and anus in females, and in the scrotum and spots on the prepuce in males). It is to be expected, as increasing numbers of hamsters are bred, that mutant types will appear. This note records the occurrence of two new mutations.

*Cream* (proposed symbol *e*). The cream is devoid of melanic pigmentation in the fur but retains the skin colouring present in the ears, genitals and hip-gland. The eyes are dark. The coat colour is a rich creamy yellow, lighter on the belly than on the dorsum. Growth, viability and fertility are comparable to the normal. Reciprocal matings of cream × normal produced a normal $F_1$ and an $F_2$ segregation of 154 normal and 58 cream ($\chi^2_1 = 0\cdot629$; $P = 0\cdot5 - 0\cdot3$). An autosomal recessive is apparently involved with normal penetrance and viability.

*Ruby-eye* (proposed symbol *ru*). The coat colour of ruby-eye animals is distinctly weakened. Both black and yellow are affected; the black to bluish and the yellow to fawn. The skin colour is appreciably paler and develops much later in the young animal. New-born animals display an annulus of pigment in the iris, clearly visible beneath the closed eyelids. When the eyes open, the pupil possesses a ruby mien in most but dull lights. As adults, the ears are faintly pigmented while the genitals are usually flesh pink. Growth-rate, viability and fecundity are all subnormal. Adult size is reduced in both sexes and the males are frequently sterile. The $F_1$ of normal ♂♂ × ruby-eye ♀♀ are normal and an $F_2$ segregated into 220 normal and 35 ruby-eyed ($\chi_1^2 = 17\cdot29$; $P < 0\cdot001$). There is a significant deficiency of ruby-eyed individuals for the assumptive inheritance of an autosomal recessive gene. Impenetrance is considered improbable since the distinction between normal and ruby-eye is sharply defined; there is no intergrading.

The estimated viability of ruby-eye homozygotes is $0\cdot477 \pm 0\cdot087$ at the recording age of twenty-one days. The lowered viability could be the result of the interplay of several factors: (1) the perishing of some *ru*-bearing gametes; (2) the selective degeneration of some *ruru* foetuses (since these probably have impaired growth); (3) a greater proneness for *ruru* young to succumb during parturition; (4) selective cannibalism of *ruru* young by the mother (again possible as a consequence of the impaired growth-rate). It may be remarked that no obviously inferior *ruru* young could be detected at birth; unfortunately the mothers resent viciously the handling of new-born young, making detailed scrutiny hazardous for the litter.

All new-born litters are examined as soon as possible after birth, thus (4) could be partitioned into (*a*) cannibalism prior to examination and (*b*) cannibalism later. The latter usually occurs within 1–3 days. Only this last factor can be analysed with the present material. If selective cannibalism occurs, it is to be expected that in litters with no or little observed cannibalism, the proportion of ruby-eye should approach more closely to a 3 : 1 ratio. The pertinent data are shown in Table 1.

Table 1. NUMBER OF YOUNG EATEN PER LITTER

| Phenotype | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
|---|---|---|---|---|---|---|---|---|
| *Ru*– | 54 | 80 | 54 | 12 | 4 | 0 | 5 | 11 |
| *ruru* | 9 | 8 | 12 | 3 | 0 | 0 | 1 | 2 |

Total number of young in litter with degrees of cannibalism or losses.

To apply a test for heterogeneity, the five classes on the right were merged, resulting in a $\chi_3^2$ of $6\cdot12$; $P = 0\cdot20 - 0\cdot10$. The data clearly fail to substantiate a claim of selective cannibalism of type 4*b*. The most favoured explanation is that of (2)—a relatively greater propensity for *ruru* foetuses to atrophy in face of *in utero* competition.

## Chromosome Number of Human Cervix Uteri

IN a recent review, Beatty[1] has shown much evidence in favour of the inconstancy of chromosome number in various somatic tissues of mammals, including man. Sachs[2], however, did not observe any variation in the chromosome number of human and some other mammalian endometrial tissues from a count of fifty nuclei in each case by using the squash technique. Walker and Boothroyd[3], using a similar method, obtained wide variations in the chromosome number in somatic tissues of mouse and to a le extent in human endometrium; but when the employed the membrane and spinning technique[6] fc the same tissues, the variations were within a narro limit. Human endometrial tissues have also bee examined by me[4] and by Timonen[5]. Except Sachs we have found variation of the chromosome numb in human endometrium, although my results[4] agr more with those of Walker and Boothroyd[3] showing a narrower range of variation than those Timonen[5]. Since the chromosome number of huma endometrium is a matter of controversy, I have bee studying the chromosome in the epithelium of no neoplastic cervix uteri with an improved technique Preliminary results for chromosome counts from o hundred nuclei have been obtained.

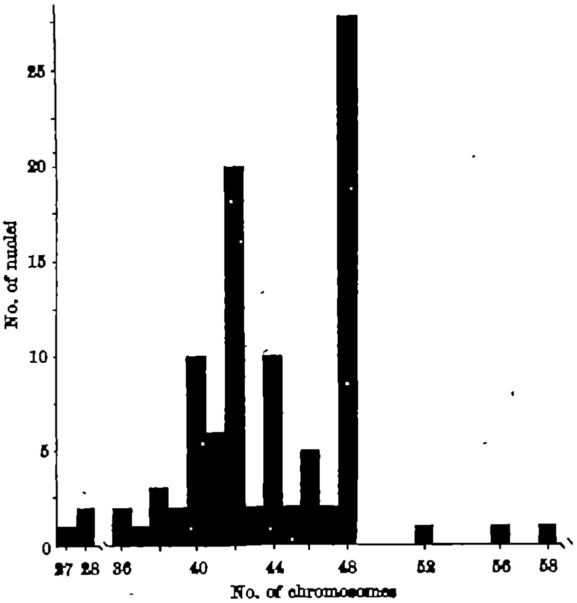

Fig. 1. Frequency distribution of chromosome number in cell from human cervix uteri

The distribution of the chromosome numbers the present work ranges from 27 to 68 (Fig. 1 Of 100 nuclei, four had the following hyperdiplo numbers: 52, 56, 58 and 68 chromosomes, twent eight nuclei had the normal diploid set, and t remaining sixty-eight nuclei had subdiploid numbe (fifty-seven of them had numbers ranging betwe 40 and 47). The frequency distribution peak w found at the diploid number, but there was al another lower peak at 42.

Some error in counting may have occurred owi to technical difficulties; but this has been min mized by various recent techniques. Hence must be concluded that variations occur in t chromosome number of normal somatic tissues of m and mammals. The results obtained with somat tissues by various workers[1] and in the present wo show that the same somatic tissue may have different chromosome number distribution in differe cells at different times, and this will be more appare when periodic regeneration and degeneration tak place[4] and mitotic abnormalities are not infreque In our study of human cervix tissue there is so indication of the existence of difference in the fr quency distribution of chromosome numbers different patients; further results will be necessa to substantiate it.

I am indebted to Dr. S. P. Ray-Chaudhuri, of the University of Calcutta, for his initiation of the present study, and to Dr. Subodh Mitra, director of the Chittaranjan Cancer Hospital, Calcutta, for his interest.

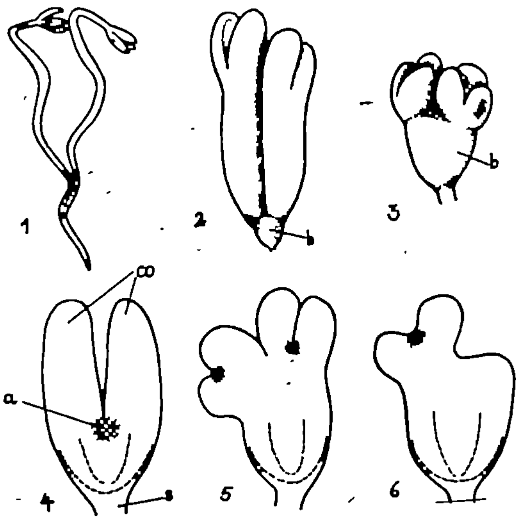
# Experimentally Induced Twinning in Plants

It is well known that characteristic changes in leaf-form and growth habit can be induced by treating shoot apices with synthetic growth substances. The question arises as to whether entire plant embryos also can be induced to develop abnormally by the action of growth regulators. For this purpose the solutions must be applied in a suitable manner to the earliest embryo stages through the growing carpel walls, or it would be necessary to remove the still quite small embryos and to expose them *in vitro* to the proper influences. Both methods are difficult to apply and have as yet proved unsatisfactory.

These difficulties can be overcome by using especially suitable material, such as mature seeds of *Eranthis hiemalis* L. *Eranthis*, in common with several other spring-flowering plants, discharges its seeds, which outwardly appear to be mature but which really contain only undifferentiated pear-shaped embryos. The development of the embryos occurs between May and December in the seeds lying in the soil[1]. Consequently, the still very small embryos in the freshly collected seeds can be exposed to the desired treatments. By successive removal of the embryos during the summer and autumn, all stages of normal and experimentally altered development can be observed.

The experiments, which were begun in 1953 and which have been continued to date, were carried out in the following manner. The freshly collected seeds were either submerged for 12–14 hr. in solutions of the active substances or were planted out in flower-pots in groups of a hundred each, and 50 c.c. of the solution was poured on. A 0·1 per cent solution of 2,4-dichlorophenoxyacetic acid caused almost 100 per cent cotyledon anomalies (syncotyly and pleiocotyly of all degrees); this contrasts with only 0·37 per cent in untreated material[2]. In addition, there was always a certain percentage (3–8) of twinning. The normal rate of twinning in *Eranthis hiemalis* is approximately 0·03 per cent. The twins were almost always fused at the base in varying degree and frequently showed cotyledon anomalies (Fig. 1). 2,4,5-Trichlorophenoxyacetic acid and α-naphthalene acetic acid produced a similar effect within the same range of concentration. With lower solution concentrations (less than 0·1 per cent) the number of anomalies decreased, while in the case of concentrations of more than 0·2 per cent lethal deformities increased.



Figs. 1–6. *Eranthis hiemalis.* (1), Twin seedling; (2 and 3) twin embryos removed in September and towards the end of June (× 110 and × 200, respectively); (4–6) longitudinal sections; (4) normally developed embryo, (5 and 6) embryos with two- and one-sided regeneration (× 280). *a*, apex; *b*, pear-shaped body; *co*, cotyledons; *s*, suspensor

In order to obtain information on the mechanism of twin origin, which is apparently the result of cleavage, various developmental stages were subjected to anatomical investigation. Fig. 2 shows a pair of twins removed from the seed in September. Here again both embryos are fused together at the root end. They originate from a pear-shaped body (*b*), the shape of which suggests that it is the original embryo itself which has regenerated two new embryos. This assumption is strengthened by viewing a still younger twin stage, as can be obtained towards the end of June (Fig. 3). Where normally both primordial cotyledons would be expected (Fig. 4), two new embryo buds with three cotyledons each have developed. A longitudinal section of the same embryo shows the relationships in a still more clear-cut manner (Fig. 5). The original embryo has developed normally in its basal part; the suspensor (*s*), the initial root cap and the new cell divisions of the procambial cylinder can be seen. However, the centrally located shoot apex is completely lacking and, in place of both cotyledons, two new embryonic upper parts with apices and cotyledon primordia have formed.

The following hypothesis may be advanced. The still undifferentiated embryo, such as is present when treatments are being carried on, already possesses an 'apical dominance'. The group of cells out of which the shoot apex later arises inhibits (either competitively or regulatively) the formation of further apices. These cells of the embryo apex are especially likely to be damaged due to the action of synthetic growth substances on the pear-shaped embryo. In this manner their influence disappears, and the cells which normally would give rise to the cotyledons grow into new stem tips.

Now we would expect, on the basis of our knowledge of correlation phenomena, that the regenerative formation of two new shoot apices would occur relatively infrequently and that a slight precocity in the one would necessarily inhibit the formation of the other. Such is the case of the embryo in Fig. 6. In place of the one cotyledon an embryonic bud has arisen while, on the opposite side, where the other cotyledon would be expected, only a few rather closely clustered nuclei suggest a short activity period. Embryos with one-sided regeneration were encountered in our material exceptionally frequently. This would tend to support our hypothesis.

In this connexion we must refer to the results of Wardlaw and Cutter[4-6]. When in the apical cone of *Dryopteris austriaca* the positions of the youngest visible primordia or of the site of the next primordium were partially isolated from the shoot apical cell by two wide tangential incisions, buds instead of leaves are formed. E. Ball[7] also obtained in *Lupinus albus*, after destroying the central portion of the shoot apex, one or two new apices by divisions of the second tunica layer in a flank position. Contrary to the results of Wardlaw in ferns, we have not observed the transformation of an already visible cotyledon primordium into a new stem apex. Treatment which occurred later than ten days after the discharge of the seeds produced no more twins, because at this time the cotyledon primordia began to differentiate.

The illustrations are based on photographic illustrations; these last will appear in a more comprehensive work to be published later.

## Displacement Activities in Fiddler Crabs

ACCORDING to Tinbergen[1], a "displacement activity is an activity belonging to the executive motor pattern of an instinct other than the instinct(s) activated", and, according to Bastock, Morris and Moynihan[2], such activities would seem to take place in two quite different situations: "(1) Displacement activities may be performed by an animal in which two or more incompatible drives are strongly activated. Each drive prevents the expression of the other(s). (2) Displacement activities may also be performed by an animal in which one drive is, at the same time, both activated and thwarted."

Displacement activities have been reported for various vertebrates, especially fish and birds. Morris[3], for example, recently described the displacement activities of the zebra finch, *Poephila guttata*.

To the best of my knowledge, no case of a displacement activity has yet been recorded for an invertebrate. However, a recent study of the behaviour of the fiddler crabs (*Uca* spp.) which occupy the mangrove swamps of Inhaca Island, off the coast of Mozambique, revealed a number of instances of displacement feeding.

For normal feeding, male *Uca* crabs use only their spooned minor cheliped, the enlarged major cheliped being held at rest. With the minor cheliped, the crab scoops up from the ground a mixture of sand or mud and organic particles, which is then conveyed to the mouth. The mouthparts separate out the organic particles until, eventually, enough sand has collected to form a pellet, which drops to the ground. The female crabs differ from the males in that they possess no enlarged cheliped, but use their two small chelipeds more or less alternately during the feeding process.

(1) Displacement feeding as a result of a conflict of incompatible drives—the drive to attack and the drive to flee—was noticed in the following four species: *U. annulipes*, *U. chlorophthalmus*, *U. marionis* and *U. urvillei*. While protecting their burrows from male intruders or being threatened by superior males, and especially between bouts of actual fighting (in all of which activities the use of the major cheliped is involved), male crabs were seen to be feeding rather agitatedly. Such individuals appeared to be highly 'nervous', the scooping movements of their minor cheliped being far more frequent and far less deliberate than those of normal feeding. During displacement feeding a negligible quantity of food actually seemed to reach the mouth—not sufficient for any sand pellets to be formed. In the field it was noticed that the majority of individuals of all the species showing displacement activity were males. Females are, generally speaking, rather timid, for—possessing no major cheliped—they are ill-equipped for fighting. If threatened by a male, they can usually manage to escape by scurrying off to disappear down their burrows; that is, in such a case, only their escape-drive is stimulated, so that no tense conflict of drives is involved, and, hence, no displacement activity is produced.

(2) Displacement activities due to the simultaneous activation and thwarting of the same drive were observed in *U. marionis*, *U. urvillei*, *U. annulipes* and *U. chlorophthalmus*, during their respective mating seasons. This type of displacement feeding was particularly noticeable in *U. marionis* and *U. urvillei*, for these species were observed when their breeding season was far advanced. *U. annulipes* and *U. chlorophthalmus*, however, were under observation when their courtship was only in its incipient stages, so that displacement activity was noticed only occasionally. Generally speaking, during the breeding season, the approach of a female frequently stimulated a male, causing him to beckon with his major cheliped several times in quick succession, in a manner characteristic of his species. In *U. marionis* males, especially, such courtship display often appeared to become very intense, with each beckoning individual standing on the very tips of his ambulatories and running a short distance to the left and then to the right, repeatedly, between individual beckoning movements. Frequently a female would appear to respond to such display by leading the male to her burrow and, perhaps, by allowing the male to stroke her carapace. Now and again, however, the display of a male crab was ignored by the female, who either continued to feed quite normally or disappeared temporarily down her burrow. In such a case, if the thwarted male were sufficiently aroused sexually, he would frequently begin to show displacement feeding, until the female concerned took notice of him, either by stopping her feeding or by reappearing from her burrow, or until, perhaps, the approach of another female distracted his attention. Thus, periods of displacement activity were often found alternating with periods of intense courtship display.

Under laboratory conditions, displacement feeding was observed in *U. inversa*. In the field, the burrows of this species are rather widely spaced, with the result that fighting over the ownership of territories is unnecessary, and, therefore, relatively rare. Hence, displacement activities are also at a minimum. However, it appeared that several *U. inversa* individuals, confined to a terrarium too small for their number, became unnaturally aggressive towards one another. Of these, one female was seen to be performing displacement feeding—the one and only case of a displacement activity observed in this particular species. The female concerned appeared to be trapped in a corner, away from her burrow, and completely surrounded by four males. She ran about nervously, trying unsuccessfully to make her escape, and even attempted to climb the vertical sides of the terrarium, falling down again and again. Finally, she began to feed, in a highly 'nervous' fashion, and, since her chelipeds appeared to be scooping up no mud whatsoever, it appears that this must be yet another case of displacement feeding.

## Cytochemical Research on Coelenterate Nematocysts

A NOTE by T. M. Yanagita and T. Wada[1] suggesting, after C. H. Brown[2], the possible keratin nature of coelenterate nematocysts has directed my attention to the subject. In 1952 I had observed the pronounced metachromatic colour produced by dilute thionin on large nematocysts from a siphonophore, *Halistemma* sp. It is known that the metachromatic colour of a dye, as taken up by a substance, is characteristic of an acidic mucopolysaccharide content, associated or not, with proteins to form mucoproteins[3]. The fact interested me, since I had studied such substances in the envelopes of pagurid and cephalopod spermatophores[4].

Another aspect of the nematocyst's contents has been studied by J. Boisseau[5]—the presumably toxic substance enclosed in the cnidocyst. He concludes that an albumin content is associated with a phenolic compound; the latter differs according to the type of cnidocyst and the species investigated.

In view of these different facts, I undertook to investigate the matter more closely, with the few cytochemical procedures available to me. Two species were chosen: a siphonophore, *Abylopsis tetragona* Ott. (*Halistemma* are not as frequent off the coast of Algiers), and an actinian, *Anemonia sulcata* Penn.

(1) *Abylopsis* has four types of nematocysts localized in the dactylozooid; I shall use Weill's[6] nomenclature to designate them eventually. I ascertained the protein constituent by means of a few colour reactions which are weakly positive (ninhydrin, Sakagushi, Millon, Adamkiewicz). The cystine content was revealed by the lead sulphide reaction. It is positive on every part of all cnidocysts, thereby confirming my predecessors' findings. The phenolic group was studied with the azo and chromaffine reactions and others special to *ortho*diphenols, according to procedures given by Lison[7]. I found that all nematocysts contain a small amount of *ortho*diphenol. This may differ according to the parts of the cyst.

The mucopolysaccharide content was analysed by means of techniques summarized by Lison[7]. The different kinds of cysts react positively to the Bauer test. Staining with toluidine blue gives different results: the invaginated (or discharged) threads and fluid content of the cnidocysts take a strongly metachromatic hue, implying the presence of a sulphomucopolysaccharide compound; the mastigophore capsules alone are to a lesser degree metachromatic too: this would indicate a simple mucopolysaccharide content (as defined by K. Meyer[3]). The other nematocyst capsules are coloured orthochromatically. They can, however, be made to colour metachromatically by treatment with 10 per cent chromic acid. These capsules would thus contain a neutral mucoprotein.

(2) *Anemonia sulcata* has several kinds of nematocysts, localized in different parts of the body. There are, besides, spirocysts in the tentacles, not considered to be true cnidocysts (Weill[6]). The protein content includes arginine, specially abundant in spirocysts, on which it confers basic properties; tryptophan is present in small quantity; cystine can be revealed by the lead sulphide and by the sodium nitroprussate reactions—the latter after reducing the S—S linkage in the amino-acid. The result is more strongly positive on the spirocysts than on the basitrichia or other kinds. The Chevremont and Fredericq test could not be of any use in this case, since it is given by other reducing agents, such as diphenols. It is likely the S—S bridges in the protein account for the sensitivity of certain parts to alkaline sodium sulphide, such as was found by Brown[2] and which I confirmed on the basitrichia capsules. The spirocysts are not wholly soluble.

The presence of an *ortho*diphenol has been identified in each type of nematocyst; the amount is very slight, as shown by the weak chromaffine reaction. The spirocysts contain an amino-*ortho*diphenol instead (giving a positive azo-reaction in acidic medium, as well as in alkaline solution).

The polysaccharide content gives a positive Bauer reaction, but as a rule very faint. Staining by toluidine blue is not strongly metachromatic on basitrichia and the contents of atrichia, since colour is due to the carboxylic groups. These nematocysts seem to be made of simple mucoproteins. But the mastigophores and atrichia capsules are not coloured; neither are the spirocysts, which, being acidophilic, do not take basic dyes. The two former can, however, be made to stain metachromatically after chromic oxidation. This would indicate that they are made up of neutral mucoproteins. The spirocysts remain uncoloured in these conditions; since they are slightly Bauer-positive, I think this indicates a low polysaccharide content linked to a basic protein. I would suggest it is a glycoprotein, as defined by Meyer[3], on account of its low carbohydrate content.

A more detailed account will be published elsewhere.

## Side-Chain Orientation in Fibrous Proteins

THE specific properties of proteins depend to a large extent upon the composition and arrangement of their side-chains, and a good deal of information has been accumulated recently on the amino-acid sequences of various proteins. Very little is known, however, of the stereochemistry of the side-chain residues and the relations between side-chain configuration and orientation and the specific properties they confer on proteins. This is largely due to the lack of direct evidence, since X-ray diffraction diagrams obtained from fibrous proteins emphasize only the similarities between the configuration of the polypeptide backbone chain, while the very much richer diffraction patterns obtained from crystalline globular proteins have, as yet, only been interpreted in very general terms[1].

In view of the paucity of information concerning side-chain orientation, Elliott's deduction[2] of a marked preference for the side-chain amide groups in crystalline ribonuclease to orient, with the HH direction parallel to the *b* crystallographic axis, is important because of the very direct nature of the experimental evidence. The preferred orientation was deduced from the dichroism exhibited by an absorption band about 5,050 cm.$^{-1}$ in the infra-red spectrum in which the associated transition moment was assumed to be parallel to the HH direction. Elliott also showed[3] that in the spectrum of horse hair dried *in vacuo* an incompletely resolved band near this frequency was dichroic, but precise observation was hampered by an overlapping absorption band about 5,150 cm.$^{-1}$ due to residual water in the specimen.

It has been found that the 5,150 cm.$^{-1}$ absorption band can be completely eliminated from the spectra of fibrous proteins by drying at 105° C. for three hours, thus enabling the 5,050 cm.$^{-1}$ absorption band to be studied in some detail. Fig. 1 shows the spectra of Lincoln wool, silk fibroin, gliadin and human hair extended 90 per cent in steam all dried in the above manner and immersed in hexachlorobutadiene. The assignment of the 5,050 cm.$^{-1}$ band to side-chain amide groups is confirmed by its relative prominence in silk, wool and gliadin, which is in accord with the amide nitrogen contents of the specimens used. Expressed as percentages of the total nitrogen, these were 1·2, 6·8 and 24·2 respectively[4].

The strong perpendicular dichroism of the side-chain amide band in wool, which is also found in unstretched hair, indicates a marked tendency for the $-CONH_2$ groups to be oriented with the line joining the two hydrogen atoms perpendicular to the fibre axis, and this is depicted diagrammatically in Fig. 2. The orientation about the HH line cannot be fixed by this observation alone; but that shown in Fig. 2 would be particularly important in establishing intermolecular hydrogen bonds. In addition, this orientation would appear to permit the formation of hydrogen bonds to the side-chains of two neighbouring polypeptide chains through the agency of a single amide group.

In hair that has been extended 90 per cent in steam the dichroism of the side-chain amide band vanishes, even though the neighbouring peptide absorption band shows considerable dichroism. The loss of dichroism could be due to a re-orientation of the amide group such that the direction of the transition moment is inclined at about 55° to the fibre axis[5]; but it seems more likely to be due to a random orientation of the HH direction in the extended condition.

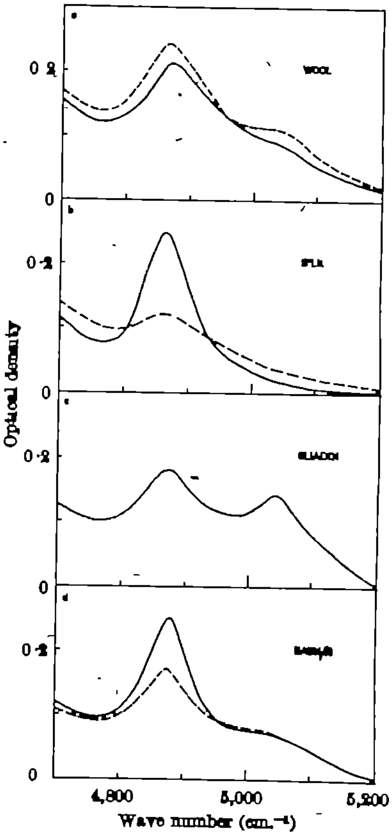

Fig. 1. Infra-red spectra obtained from (*a*) Lincoln wool fibres, (*b*) silk fibroin, (*c*) powdered gliadin and (*d*) human hair stretched 90 per cent in steam. In each case the specimen was dried at 105° C. for 3 hr., to reveal the side-chain amide absorption c. 5,050 cm.$^{-1}$. In *a*, *b* and *d*, the full curve was obtained with the electric vector vibrating parallel to the fibre axis and the broken curve with the electric vector perpendicular

Additional information on the site of the amide side-chains was obtained by allowing oven-dry wool to react with deuterium oxide. The replacement of hydrogen by deuterium causes a considerable reduction in frequency of vibrations involving hydrogen atoms, thus indicating the accessibility of particular groups to deuterium oxide[6]. After 16 hr. immersion at 20° C. the optical density of the peptide band at 4,870 cm.$^{-1}$ was reduced to about one-half of its original value, while the amide band was no longer detectable.

It has been assumed that the fraction inaccessible to deuterium oxide is crystalline, and this forms the basis of a method of determining the crystallinity of wool[7]. If this is correct, the side-chain amide groups

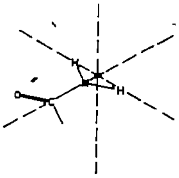

Fig. 2. The relation between the direction of the fibre axis and that of a line joining the two hydrogen atoms of the side-chain amide groups in wool and hair deduced from the perpendicular dichroism of the 5,050 cm.$^{-1}$ absorption band

ust be concentrated in the amorphous regions of the ibre but at points where there is considerable preerred orientation of the molecular chains parallel to he fibre axis.

It is implicitly assumed, in the above method of etermining crystallinity, that there is a uniform istribution of side-chains throughout the crystalline nd amorphous regions. In view of the complete xchange of the amide groups, this assumption does ot appear to be valid and the values of crystallinity btained by this method are probably too low.

Alternatively, it might be argued that amide roups are present in the crystalline regions but are ccessible to deuterium oxide, and this would be onsistent with the infra-red measurements. In this ase the basis of the deuterium exchange method of etermining crystallinity would then be invalidated.

Of the two interpretations the former is the more ttractive, as the amide-containing side-chains are elatively bulky and might be expected, from recent ork on silk[8], to be concentrated in the amorphous egions.

## Reverse-Shearing Interferometry

THE introduction of the shearing principle in the xamination of optical wave-fronts by interferometry[1] as led to a great simplification of the apparatus equired. Recent developments[2,3] have made possible he construction of compact portable interferometers r the examination of optical systems of large size, nd several instruments are now available from ptical manufacturers. For some purposes, however, is possible to use as a shearing interferometer an ven simpler system which is already in wide use for nother purpose. This is the square prism used in hotometry for dividing a beam of light into two. is composed of two similar right-angled prisms emented at their hypotenuse faces after one face as been coated with a semi-reflecting film. An pplication of this prism to the interferometry of ngth was first described by Kösters[4], but the rism is also very useful as a shearing interferometer.

Two alternative arrangements may be used if the ystem is a reflecting one; these are shown in ig. 1. The source $S$ may be the filament of a small ashlamp bulb, or an illuminated pinhole; in some ases the reflexion of a distant window or lamp in e convex surface of a steel ball will provide a suitble source. The system shown is a concave mirror, , arranged so that the light from $S$ which emerges om the prism is reflected back into the prism. The iginal beam is split into two at the interface during e passage through the prism, and each of these parts split again in the prism after reflexion at the system der test. Thus four beams finally emerge from the prism. Two are directed towards the source $S$, and the position of $M$ is adjusted until they both produce an image of $S$ coincident with $S$. Then the remaining two beams will form two more images of $S$, which coincide, at $S'$. If the eye is placed at $S'$ looking into the prism, two images of the aperture of $M$ are seen. One of these images is a mirror image of the other, and the region in which they overlap is crossed by interference bands. The overlap of the images may be controlled by rotating the prism, and the separation of the bands may be altered by tilting $M$.

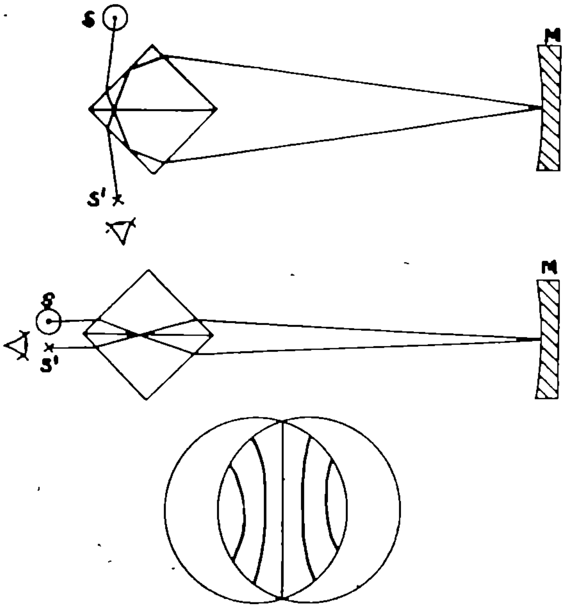

Fig. 1. Two alternative arrangements for using a beam-splitting prism as a shearing interferometer, and an example of a pattern produced by a system with 0 25 wave-length of primary spherical aberration

Systems such as camera lenses, which do not reflect, can be examined by using a second beam-splitting prism to recombine the two beams produced by the first prism; but it is simpler and gives a more sensitive test of aberration to place a mirror behind the lens and to treat the lens and mirror combination as a reflecting system.

When the two images of the aperture of the system appear to coincide (zero shear) the bands should be quite straight. Any lack of straightness shows a lack of mirror symmetry in the wave-front after reflexion at $M$. If the test is repeated for a few meridians, and the bands remain straight in all cases, the surface of $M$ must be a surface of revolution, and Bates's[1] procedure for the analysis of the interferograms obtained by shearing the apertures may be followed. Further, the pattern which is obtained from a reverse-shearing interferometer will be exactly the same as one which could be obtained from a non-reversing interferometer with the same shear.

The main disadvantage in the use of this prism is common to all 'solid' interferometers, and arises from the difficulty of adjusting the band separation in a direction at right angles to the direction of shear. On the other hand, the compactness of the system is noteworthy, and the interferometer remains sensitive to comatic error at zero shear, when all symmetrical aberrations have no effect on the pattern. This latter property has been investigated in more detail and will be reported elsewhere[5].

The work described above has been carried out as part of the research programme of the National Physical Laboratory, and this communication is published by permission of the Director of the Laboratory.

## Embrittlement of Tungsten Wire

THE embrittlement of tungsten wire heaters for oxide cathodes has been a frequent source of trouble to the vacuum-tube engineer. The trouble has persisted despite the many technological advances made in the manufacture of the wire and in its subsequent handling.

In the processing of a heater the wire is coated with a refractory oxide (normally alumina) and the coating fired to hardness in an atmosphere of wet hydrogen at a temperature usually above 1,500° C. It is customary to test the quality of a batch of wire by submitting it to firing tests under somewhat more exacting conditions (of temperature and time) than would be met in normal processing: the singular feature of the type of embrittlement to which we refer is that it frequently occurs in heaters made from wire which on such firing tests has appeared to be of excellent quality.

The purpose of this communication is to direct attention to what is, we believe, one of the major causes of such embrittlement, namely, surface contamination of the tungsten by nickel. We have found that very slight traces of nickel on the tungsten surface can cause embrittlement. The amount of nickel which is significant is extremely small: a film of the order of 10 A. thick on the surface of otherwise good-quality wire can make that wire so brittle that it cannot be handled, and even smaller amounts can materially impair ductility.

Such traces of nickel are readily picked up on the surface of a heater during the normal processes of manufacture. Making use of electrographic techniques, we have found nickel contamination in damaging quantities to arise from such practices as bending the wire around a nickel former, or winding it over nickel rollers or on to nickel-alloy spools. Spot welding of an uncoated heater to nickel wire can splash embrittling quantities of nickel on to the tungsten in patches as far as two inches from the weld.

On heating contaminated wire there is rapid diffusion of the nickel into the tungsten; when this diffusion occurs the wire is embrittled (brittleness is not apparent at temperatures below about 1,200° C.); but if the contaminated surface of the tungsten can be removed before being heat treated, so that no diffusion of nickel takes place, the wire is undamaged.

Work is proceeding to ascertain whether or not the related elements, iron and cobalt, exhibit similar embrittling properties. Preliminary indications are that both metals do so—iron only slightly, and cobalt to a lesser extent than nickel.

We cannot yet offer a theoretical explanation o these phenomena.

## Large Type II Diamonds

IN an article on "The Problem of the Two Type of Diamond" by Prof. G. B. B. M. Sutherland, D. E Blackwell and W. G. Simeral[1], it is remarked tha "in our experience all large diamonds of gem-ston quality are always type I diamonds". Actually the four largest and finest diamonds we have com across at the Diamond Research Laboratory sinc 1951 were all of type II. Some details are given i Table 1.

Table 1

| Type | Weight in carats | Colour | Origin | Transmittance in ultra-violet | Laminations | Lit. reference |
|---|---|---|---|---|---|---|
| II | 34½ | Pure white | Premier Mine | Down to 2250 A. | Present | *Research*, 4, 131 (1951) |
| IIb | 66 | Pure white | Premier Mine | Down to 2750 A., and probably shorter | Present | *Physica*, 18, 489 (1952) |
| IIa | 160 | Pure white | S.W. Africa | Down to 2375 A. | Present | Laboratory Report No. 94, May 1, 1951 *Gems and Gemmology*, 7, 275 and 287 (1953) |
| IIb | 426½ | Pure white | Premier Mine | Down to 2375 A. | Present | *J. Gemmology*, 4, 300 (1954) |

The difference between types IIa and IIb is tha IIa is an excellent insulator for electricity whereas II is a temperature-sensitive semiconductor. Type II shows, moreover, a green-blue phosphorescence afte having been irradiated with short-wave ultra-viole (resonance line of mercury, about 2536 A.) wherea type IIa does not. None of the diamonds of Table fluoresces in the near ultra-violet, that is, abou 3650 A. At the time when the 34½ carat diamon was examined, the existence of type IIb diamond was still unknown.

The diamonds of Table 1 are all of the finest gem quality, and it is my firm opinion that nearly a the larger gem stones belong to this category. How ever, it is true that not one of the larger gem diamond shows a regular crystal form. Quite a few of the show not only growth triangles but also growt figures of a hexagonal shape.

Finally, it is worth while mentioning that th Premier Mine produces a very much higher percentag of type II diamonds than any other mine.

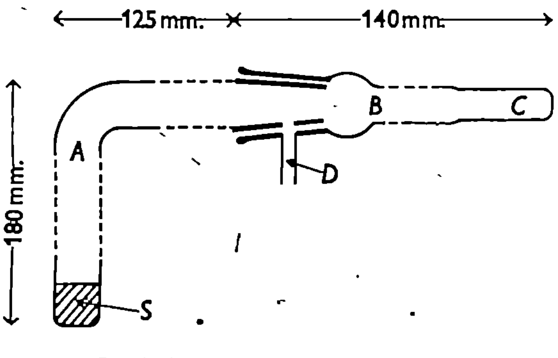
## Effect of Ionizing Radiation on Hæmoglobin and Cytochrome c

THE study of the oxygen-effect in ionizing radiation may elucidate the part which indirect effects play in inhibiting biological cell functions through the action of oxidizing radicals and hydrogen atoms, which are formed from water. In continuation of previous work[1] the following substances have been exposed to X-rays: oxyhæmoglobin ($HbO_2$) in air, hæmoglobin (Hb) in nitrogen, methæmoglobin (Methb) in air and in nitrogen, reduced and oxidized cytochrome c in air and in nitrogen. The concentration of hæmoglobin in phosphate buffer pH 6·0) varied between $1·3 \times 10^{-4}$ and $3·2 \times 10^{-4}$ M and that of cytochrome c (in phosphate buffer pH 7·3) between 0·8 and $2·0 \times 10^{-5}$ M. The X-ray dose varied between 0·8 and 75·0 kr. (190 kVp., no added filtration, dose-rate 1·8 kr./min.). Changes in absorption spectra of the substances examined, which were measured spectrophotometrically, were a measure of the irradiation effect.

The spectra after irradiation were found to be unstable and to alter with time, especially with samples irradiated in nitrogen. This was due to the fact that the irradiated substances had become easily oxidizable, and was most pronounced with cytochrome c. In order, therefore, to prevent changes of the spectra which, although induced by radiation, occurred only subsequent to irradiation, they had either to be fixed in the state obtaining at the end of the irradiation procedure, or oxygen had to be excluded during measurement. The former was done with hæmoglobin by means of carbon monoxide, which combines with the reduced form and prevents further oxidation by molecular oxygen. Reduced cytochrome c, on the other hand, which does not combine with carbon monoxide, cannot be so protected. Experiments with cytochrome c were therefore carried out in a special tube (Fig. 1), which allows irradiation and spectrophotometric measurement to be carried out without exposing the irradiated sample to air.

The design of the tube, which can be evacuated and filled with nitrogen, is self-explanatory. The sample S is irradiated in A and then tipped through B into the optical cell C (which is protected by lead during irradiation). Parts A and B are separated from each other while nitrogen under pressure is applied through D, and B is closed with a ground-in glass stopper. An adaptor to the spectrophotometer, which excludes the light, allows the spectrum to be measured in the ordinary way. The results obtained are briefly as follows.



1. Combined irradiation- and spectrophotometry-tube

(1) *Hæmoglobin.* The primary change depends on the initial state of the material, that is, whether it is oxidized or reduced, and is independent of the presence of oxygen. Thus hæmoglobin becomes oxidized and methæmoglobin becomes reduced. The oxidation of oxyhæmoglobin in air and of hæmoglobin in nitrogen is of about the same order, while reduction of methæmoglobin is greater in nitrogen than in air. The rate of oxidation or reduction increases with increasing X-ray dose; conversely, at a given dose, it increases with decreasing concentration of hæmoglobin. Oxidation or reduction, however, is in neither case directly proportional to the X-ray dose, because of the occurrence of secondary reactions. Thus, for example, methæmoglobin, which becomes reduced during irradiation in nitrogen (presumably by hydrogen atoms), is re-oxidized (presumably by hydroxyl radicals). Moreover, it is not re-oxidized to methæmoglobin but to a green pigment showing a strong band at 615 mμ. The rate of this secondary oxidation is greater in nitrogen than in air, and in both cases it is the greater the lower the concentration of hæmoglobin.

(2) *Cytochrome c.* Like hæmoglobin, ferrocytochrome becomes oxidized both on irradiation in air and in nitrogen—the rate of oxidation being greater in air—and ferricytochrome becomes reduced on irradiation in nitrogen. Unlike hæmoglobin, on the other hand, ferricytochrome does not appear to be affected by irradiation in air at doses up to 35 kr. (denaturation of the protein at high X-ray doses is outside the scope of this work). There is, furthermore, no formation of a green pigment from either ferri- or ferro-cytochrome during or after irradiation in air, nor during irradiation in nitrogen. However, cytochrome irradiated in nitrogen turns rapidly green on admission of oxygen after irradiation. This occurs irrespective of whether the sample had been partially oxidized or reduced during irradiation, and is accompanied by the disappearance of the band of ferrocytochrome at 550 mμ and the appearance of a new band at about 600 mμ. Failure to observe anaerobically irradiated cytochrome without exposing it to molecular oxygen had previously led to the statement[2] that no difference exists between aerobically and anaerobically irradiated ferrocytochrome. This was coupled with theoretical considerations concerning the oxygen effect, which are now no longer tenable.

The catalytic activity of irradiated cytochrome c was finally tested by determining the rate at which it catalyses the oxidation of sodium succinate in an enzymic system (horse kidney preparation) which is otherwise practically devoid of cytochrome c[3]. After a dose of 36 kr. in air, the rate of succinic oxidation was decreased by only 15 per cent, which is accounted for by destruction of the cytochrome (as calculated from the absorption at 550 mμ after addition of sodium hyposulphite). When applying the same dose in nitrogen, the loss of catalytic activity was slightly larger, namely, 35 per cent. It is believed that this additional loss of activity is due to the fraction of cytochrome which had been irreversibly oxidized to a green pigment on admission of oxygen after the irradiation.

The experiments thus show that, while the initial reaction brought about by ionizing radiation is mainly dependent on the state of the material and its ability to react with either oxidizing or reducing agents independently of the presence of oxygen, the initial reaction product may undergo secondary, or even a series of further, changes during irradiation or, as with cytochrome *c*, after irradiation on admission of oxygen to an anaerobically irradiated sample.

## Paper Electrophoresis of Polyhydric Alcohols

The polyhydric alcohols or polyols are a group of carbohydrates important both biologically and industrially. Apart from laborious column techniques[1], there is no satisfactory micro-method available for the resolution of mixtures of hexitols (sugar alcohols) by themselves or, in particular, in the presence of hexoses.

Several workers[2] have reported on the application of paper chromatography to this problem but have stated that they found the separation of sorbitol, mannitol and dulcitol from one another and from glucose impossible, since their $R_F$ values in a great number of different solvent systems were practically identical. Cassmir and Huygens[3] reported recently that they succeeded in separating sorbitol from some simple sugars by running multiple two-dimensional chromatograms or one-dimensional chromatograms for 150 hours with butanol–benzene–pyridine–water (5 : 1 : 3 : 3)[4] as the solvent system. With a different solvent the separation of sorbitol from mannitol was possible in the same time, but neither sorbitol nor mannitol could be separated from dulcitol.

Michl[5] described the separation by paper electrophoresis of three polyols of widely differing mobilities, namely, ethylene glycol, glycerol and mannitol.

The application of the author's high-voltage technique[6] to the resolution of mixtures of polyols and sugars as sugar-borate complexes proved it to be a powerful tool, even in cases of small differences in mobilities, for example, mannitol and glucose, or sorbitol and fructose. Fig. 1 illustrates some of the results obtained.

*A* shows the clean separation of the three hexitols from one another and the tetritol (erythritol) in three hours at 2,000 V. in 0·05 *M* borate buffer of *p*H 9·2; *B* shows the result obtained by doubling the voltage and reducing the time to one-half. Agreement is quite good with regard to the directly proportional relationship between migration-rates and applied potential gradients. The slight displacement of the two erythritol spots is an effect occasionally noticed, the course of which is suspected to be uneven pressure exerted on the paper strip by the cooling plates, and is at present under investigation. The application of such high potential gradients as 80 V./cm. and current values of up to 10 m.amp./cm. proved to be feasible, although entailing an energy dissipation of up to 200 watts. The temperature of the cooling water (tap water) is significant in this case. The separation of the hexitols from the hexoses glucose, fructose, mannose and sorbose is shown in Fig. 1, *C* and *D*.

Inositol, a cyclitol, although having a slightly lower mobility than glycerol, is not easily separated from it (Fig. 1, *E*). Two important trioses, dihydroxyacetone and glyceraldehyde, though not belonging to the group of polyols, but the detectability of which in mixtures of metabolic products is highly desirable, cannot be separated because their mobilities appear to be similar. These compounds, however, can be separated by paper chromatography using the solvent system *n*-propanol : water : ethyl acetate (7 : 2 : 1)[7] in less than thirty hours, while the separation of adonitol from sorbitol (Fig. 1, *F*) can be achieved in forty hours. The difference between the slightly lower mobility of adonitol, a pentitol, and that of the nearest hexitol, sorbitol, is not sufficient to enable an electrophoretic separation to be effected. Of further interest in Fig. 1, *F* is the great difference in migration-rates between penta-erythritol, carrying no charge, and erythritol. The spreading of the penta-erythritol spot is obviously due to the nature of the compound. Lead tetra-acetate in benzene, according to Buchanan

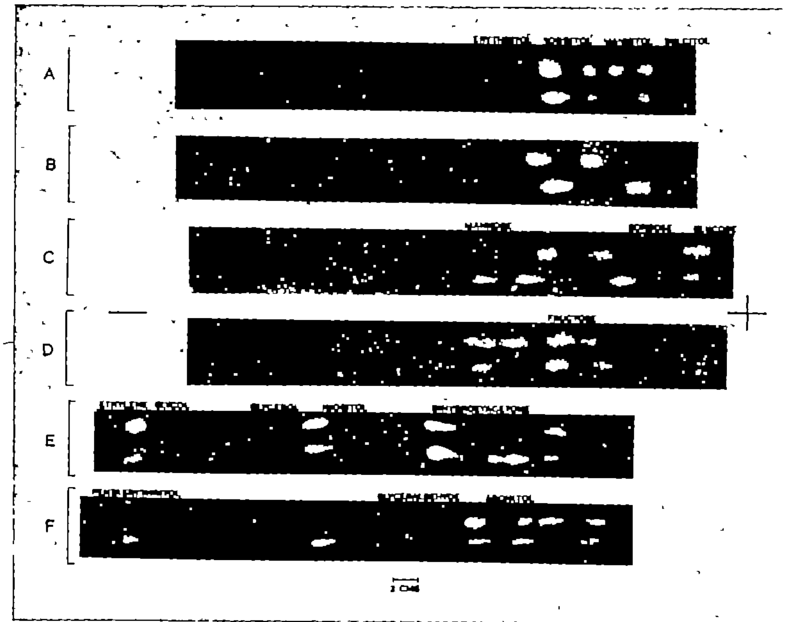

Fig. 1. Electrophoresis of polyhydric alcohols. From left to right. *A*, meso-erythritol, D-sorbitol, D-mannitol, dulcitol; conditions: 40 V./cm., 3 8 m.amp./cm., Whatman No. 3 *MM* 2½ × 22½ in. strip, 0 05 *M* sodium borate solution, *p*H 9 2, 10 μgm. of each compound, except for 20 μgm. of erythritol, applied 4 in. from cathode end, 3 hr.; *B*, erythritol; sorbitol, mannitol; conditions: 80 V./cm., 6 5 m.amp./cm., 20 μgm. of each compound, 1·5 hr., otherwise the same; *C*, mannose, erythritol, sorbitol, mannitol, glucose, sorbose; conditions: 80 V./cm., 8 5 m.amp./cm. 30 μgm. of mannose, 40 μgm. of sorbose and glucose, 1 5 hr.; *D*, mannose, erythritol, sorbitol, mannitol, fructose, sorbose, glucose; 40 V./cm., 3·4 m.amp./cm. 10 μgm. of fructose, 2·5 hr.; *E*, ethylene glycol, glycerol, meso-inositol, dihydroxyacetone, erythritol, sorbitol, mannitol, dulcitol; 80 V./cm., 7 7 m.amp./cm. 50 μgm. of ethylene glycol, 20 μgm. of glycerol, 1 hr.; *F*, penta-erythritol, ethylene glycol, glycerol, erythritol, DL-glyceraldehyde, adonitol, sorbitol, dulcitol; 80 V./cm., 10 m.amp./cm., 80 μgm. of penta-erythritol, 1 25 hr.; spraying reagent: 1 per cent solution of lead tetra-acetate in benzene, giving white spots on brown background

*al.*[3], was found to be the most suitable spraying agent, and was used throughout, as it did not pear to be inhibited by the presence of borate ions, contrast to silver nitrate. Good results have also en obtained with the separations of the glycols and eir derivatives.

Thanks are due to Mr. H. C. S. de Whalley, director research, for encouragement, and the directors of ate and Lyle, Ltd., for permission to publish this mmunication.

## The Huxley-Wilberforce Debate: a Postscript

THE famous occasion when T. H. Huxley crossed vords with Samuel Wilberforce, at the 1860 Oxford eeting of the British Association, has been often scribed; and recently D. J. Foskett has published[1] uxley's contemporary account of the encounter. here has recently come to light the draft (in a box e in the basement of the Zoology Department of e Imperial College of Science and Technology) of a te sent by Huxley to Wilberforce early in 1861, follows:

> The Athenaeum.
> *Jany 3rd*, 1861.
>
> Professor Huxley presents his compliments to the rd Bishop of Oxford—Believing that his Lordship has great an interest in the ascertainment of the truth as mself, Professor Huxley ventures to draw the attention the Bishop to a paper in the accompanying number the *Natural History Review* "On the Zoological Rela- ons of Man with the Lower Animals".
>
> The Bishop of Oxford will find therein full justification r the diametrical contradiction with which he heard of. Huxley meet certain anatomical statements put rth at the first meeting of Section D, during the late sion of the British Association at Oxford.

Unfortunately, we do not have Wilberforce's reply if any were sent—to this polite but delicately rbed note.

The *Natural History Review* had been taken over Huxley and some friends for publication in gland, having earlier been published in Ireland der the editorship of Edward Perceval Wright, d it was the first number under the new manage- ent which was sent to Wilberforce. "The tone of e Review", Huxley had told Hooker[2], "will be mildly episcopophagous"—a prospect which apparently outweighed the urgings of Darwin[3], Hooker[4] and Lyell[5] that Huxley should not take upon his already heavily burdened shoulders this new editorial duty. Before long, the substance of Huxley's paper was being given in more popular form, as six lectures to working men at the School of Mines in Jermyn Street, under the title "On the Relations of Man to the rest of the Anl. Kingdom"[6]; and after a few lectures Huxley was writing to his wife[7], "My working men stick by me wonderfully, the house being fuller than ever last night. By next Friday evening they will all be convinced that they are monkeys".

The publication of these working-men's lectures in the *Natural History Review* led to an invitation to cover the same ground before the Edinburgh Philosophical Institute. "Fancy unco guid Edinburgh requiring illumination on the subject!" Huxley wrote[8] to his wife. "They know my views, so if they do not like what I shall have to tell them, it is their own fault". Darwin's diplomatic ambiguity, "Light will be thrown on the origin and the history of man", was not for Huxley; as he put it to Hooker[9], "I told them in so many words that I entertain no doubt of the origin of man from the same stock as the apes". On reading an account of the lectures, Darwin wrote[10] jubilantly, "By Jove you have attacked Bigotry in its strong-hold. I thought you would have been mobbed"; and Lyell[11] urged Huxley to tone down some of the passages when he came to publish his little book, "Evidences as to Man's Place in Nature". Huxley accepted some of Lyell's suggestions, but[12] he found it "a great piece of self-denial . . . and I hope I shall be rewarded for the virtue". As he saw more of the proofs, Lyell became really alarmed and wrote[13], "if the worst is in sheets not yet thrown off do let me see it that I may try & suggest something of the suaviter in modo—", adding as a monitory postscript, "I hope you send none of these *dangerous* sheets to press without Mrs. Huxley's imprimatur". However, the book went to press and was a great success. As Huxley wrote to Lord Rosebery some thirty years later[14], "abuse for six or seven years . . . is not of the greatest consequence, when one happens to be in the right & stands to one's guns. But you really cannot imagine what a disreputable person the author of M.P. in N. was in the decade 1860–70—and now the doctrines of that horrid book are taught in the schools".

Grateful acknowledgment is made to the Governing Body of the Imperial College of Science and Technology for permission to quote from the Huxley Papers in its possession.

# FORTHCOMING EVENT

## Saturday, August 27—Friday, September 2

Institute of Medical Laboratory Technology (at the University, Nottingham)—Seventh Triennial Conference.

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Advisory Officer (with an honours degree in agriculture or pure science, and a special interest in grassland work) in Agricultural Botany—The Secretary, Edinburgh and East of Scotland College of Agriculture, 13 George Square, Edinburgh 8 (August 27).

Assistant, Grade B (with a good honours degree in chemistry, and preferably with teaching experience) to teach chemistry of the standard of intermediate science—The Clerk to the Governors, Woolwich Polytechnic, London, S.E.18 (August 27).

Assistant, Grade B (graduate in electrical engineering or with equivalent professional qualifications and appropriate industrial experience, and preferably with experience in the U.H.F. field) in Electrical Engineering—The Registrar, Hatfield Technical College, Roe Green, Hatfield (August 27).

Research Assistant in Pharmacology—The Registrar and Secretary, The University, Bristol (August 27)

Senior Research Student in either Engineering or Metallurgy—The Registrar, University College, Singleton Park, Swansea (August 27).

Senior Research Officer (with a degree in mathematics or one of the natural sciences, and preferably with experience of planning and conducting surveys) to work as one of a team establishing data on which design may be based, with particular responsibilities in the field of studying functional requirements of laboratory and agricultural buildings—The Director, The Nuffield Foundation, Nuffield Lodge, Regent's Park, London, N.W.1 (August 31).

Assistant Experimental Officer (with a degree in botany or an allied biological science) in the Department of Plant Breeding, to assist with cytological studies of horticultural crops—The Secretary, John Innes Horticultural Institution, Bayfordbury, Hertford, Herts (September 3).

Soil Conservation Officers (graduates in agriculture or agricultural engineering) in the Federal Department of Conservation and Extension, Federation of Rhodesia and Nyasaland—The Secretary, Rhodesia House, 429 Strand, London, W.C.2 (September 6).

Lecturer in the Department of Electrical Power Engineering and a Lecturer in the Department of Electronic Engineering—The Registrar, The University, Liverpool (September 10).

Assistant Plant Nutrition Chemist (with a degree in science or chemistry, preferably with honours)—The Secretary, West of Scotland Agricultural College, 6 Blythswood Square, Glasgow, C.2 (September 12).

Lecturer in Biology at the University of Adelaide, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Adelaide, September 15).

Lecturer (preferably with special qualifications in organic chemistry) in Chemistry—The Secretary and Registrar, University College of North Wales, Bangor, North Wales (September 15).

Scientific Assistant (M.R.C.V.S. or its equivalent; or a degree in science or in arts, and a knowledge of languages)—The Director, Commonwealth Bureau of Animal Health, Veterinary Laboratory, Weybridge, Surrey (September 15).

Reader in Applied Mathematics at the Imperial College of Science and Technology—The Academic Registrar, University of London, Senate House, London, W.C 1 (September 21).

Lecturer in Physical Geography at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C 1 (Australia, September 24).

Senior Lecturer in Civil Engineering (Hydraulics), and Senior Lecturer in Civil Engineering at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, September 30).

Lecturer in Economic Statistics—The Secretary of Faculties, University Registry, Oxford (October 1).

Assistant, Grade B (with graduate or A.R.I.C. qualifications) in Chemistry—The Principal, Technical College, Queen Street South, Huddersfield.

Assistant Statistician (with a degree in mathematics with statistics or equivalent qualifications, and preferably with an interest in the use of punched-card machines and electronic computing equipment) in the Department of Statistics, to carry out the more advanced type of statistical computations and to supervise the routine statistical work of the computing staff of the Department—The Secretary, Rothamsted Experimental Station, Harpenden, Herts.

Computer (preferably woman graduate) in the Mathematics Department—The Assistant Secretary, University College, Gower Street, London, W.C.1.

Head of the Department of Chemistry (including Colour Chemistry and Dyeing)—The Principal, Technical College, Queen Street South, Huddersfield.

Laboratory Assistant in the Physics Department—The Bursar, Epsom College, Surrey.

Metallurgist (with a first- or second-class honours degree or equivalent qualification in metallurgy, and several years research experience on non-ferrous metals, preferably including copper and aluminium alloys) at the Ministry of Supply Armament Research and Development Establishment, near Sevenoaks, Kent, for research and development in the field of non-ferrous metallurgy—The Ministry of Lab[redacted] National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting F.606/5A.

Physicist, Basic grade (honours graduate in physics and interest in a career in medical physics, and preferably with a specialized kno ledge in one of the following fields: electronics, physical chemist radiology)—The Medical Superintendent, Dundee Royal Infirmar Dundee.

Physicist (with experience of electronic techniques) in the Da Faraday Research Laboratory of the Royal Institution, to carry o research on methods of dating archaeological material by means radio-carbon measurements—Sir Lawrence Bragg, F.R.S., The Ro Institution, 21 Albemarle Street, London, W.1.

Physicists (Scientific Officer and Experimental Officer class) the Reactor Physics Division, to study the physical princip underlying a wide variety of nuclear reactors—The Establishme Officer, United Kingdom Atomic Energy Authority, Atomic Ener Research Establishment, Harwell, Didcot, Berks, quoting 2/103/3

Physicists (with an honours degree in physics, Associates of t Institute of Physics, or equivalent qualifications) at Windscale Wor Cumberland (Ref. 1,063), and Dounreay Works, Caithness, Scotla (Ref. 1,064), to be responsible to Group Managers for the efficie operation of the Health Physics and Safety Groups—The Recruitme Officer, United Kingdom Atomic Energy Authority, Industrial Gro Headquarters, Risley, near Warrington, quoting appropriate Ref. N

Research Assistant (graduate in chemistry and preferably interest in, or experience in, physical and colloid chemical techniqu in the Department of Chemistry and Food Technology, for wo on fats or allied substances (phospholipids)—The Secretary, Borou Polytechnic, Borough Road, London, S.E.1.

Senior Experimental Officer (with at least H.S.C. in scien subjects or equivalent qualifications, and experience in inorganic a radiochemical analysis) in the Chemical Engineering Divis to supervise and train staff engaged on analytical problems associat with pilot plant operation—The Establishment Officer, United Kin dom Atomic Energy Authority, Atomic Energy Research Establi ment, Harwell, Didcot, Berks, quoting 2/103/301.

Theoretical Physicist (Principle or Senior Scientific Officer gra (with a first- or second-class honours degree in physics and at le three years postgraduate research experience, preferably in the fi of motion and coagulation of particulate suspensions), to work problems of size distribution in coagulating and dispersing particul suspensions—The Senior Recruitment Officer, Atomic Weapo Research Establishment, Aldermaston, Berks, quoting 726/34.

Zoologist (Senior Scientific Officer or Scientific Officer grad (university graduate with first- or second-class honours), for gene and experimental work on marine plankton—The Director, Mari Station, Millport, Isle of Cumbrae, Scotland.

# SCIENTIFIC MAN-POWER IN BRITAIN AND ITS UTILIZATION

THE eighth annual report of the Advisory Council on Scientific Policy, covering the year April 1954–March 1955 (Cmd. 9537. London: H.M.S.O. 4*d.* net) does not, like the previous report, range over the whole field of the Council's work. It discusses five topics; but with the exception of one, the Institute of Seaweed Research, they are all inter-related, and essentially the report is a statement of the Council's views on the nation's resources and the deployment of scientific man-power, to which theme the whole of its fifth report was devoted. Indeed, the Council's inquiry as to whether further research work on seaweed should be encouraged at the Institute of Seaweed Research, and if not, what use could be made of the staff and facilities of the Institute, has also clearly been dominated by considerations of the present shortage of skilled research workers in Britain. This particular inquiry was undertaken at the request of the Development Commission, and the Biology Committee of the Council, while satisfied as to the value of the results obtained and the competence with which the work had been carried out, recommended that experimental work on the mechanical harvesting and drying of seaweed should be terminated, and other arrangements made for the continuation of research on algal chemistry. Research was already advanced far enough to permit reasonably rapid exploitation of seaweed if need arises, but earlier hopes that alginates would serve as a technically and economically desirable source of chemicals have been disappointed. The Committee could suggest no other major subject of research for which the Institute, as constituted, seemed specially suited, and in endorsing these conclusions the Council observes that an Institute with a wider field of interest, or one which forms part of a large research organization, is better adapted to divert its effort into fresh channels when experience indicates that this is desirable.

This comment is sound enough as applied to institutions mainly supported by the State, at least in present circumstances, and it emphasizes the importance of the continuing and periodical review of the work and functions of existing research institutions in relation to national needs. But it also emphasizes the importance of the independent research institution, which can afford to explore lines of investigation not sufficiently promising to justify State support. Again and again such independent bodies have proved the growing points of scientific achievement, and the corollary of any tightening of central control of the work of the State's own research institutions should be a generous and enlightened attitude to the independent institutions able to cover the gaps.

Thus this minor and particular inquiry points to the same need for an imaginative and enterprising direction at the centre, in order that the man-power resources of Britain may be wisely and most efficiently deployed, as does the Advisory Council's examination of the further problems of science teachers and scientific man-power, recruitment to the engineering industry, Colonial research and scientific libraries. On the second topic, its comment is indeed reserved. An inquiry conducted by the Council's Scientific Man-Power Committee revealed considerable differences of opinion within the engineering industry both as to the effect of university expansion on the recruitment of apprentices and as to the value to industry of certain forms of postgraduate work in engineering at the universities. The Council is examining in further detail the issues involved and hopes to report on them later in the year.

Meanwhile, it is sufficient to note that the Advisory Council has already emphasized the important bearing of these matter on educational policy, with which the question of the shortage of science teachers is as closely related as it is with the scientific man-power situation. On that subject the Council's analysis is not, of course, so deep as that of Sir Edward Appleton's committee, although the latter was concerned only with the supply of teachers of science and mathematics in Scotland. The Advisory Council's review, however, is set in a wider context and in itself demonstrates the futility of attempting to deal with problems on departmental lines. The issues and implications are too serious for the shaping of educational policy and scientific policy to be scattered over unrelated departments without a far more determined and imaginative effort at Cabinet level to devise a policy consistent with national needs than has yet been apparent.

The Advisory Council appears to be aware of this, though it might have expressed the matter more forcefully. It recognizes the danger arising if the number of students now graduating in science and mathematics, though more than twice that in 1939, continues to fall short of the current demand for scientists, still less to keep pace with the steady increase in demand. The scale of the scientific effort of Britain, which depends on the numbers and quality of the trained scientists and technologists available, conditions both the effectiveness of the national economy and the security of our defence. Nor can the universities and the colleges of technology play their part unless there is an adequate flow to them of boys and girls who have been introduced to science by teachers capable of revealing its attractions and interests and the careers to which it may lead.

Hence follows the seriousness of the decline in quality of newly recruited science teachers since the War, and of the threatened more serious shortage unless the rate of recruitment rises as the secondary school population increases and as more boys and girls remain at school until the age of university entrance. The latest information which has reached the Advisory Council suggests that the number of graduate science teachers in the schools has risen appreciably during the past two years. Figures quoted for England and Wales show an increase from 14,419 in 1952 to 15,335 in 1954; for maintained grammar schools, the corresponding figures are 7,659 and 7,910, the increases being fairly equal in each year in both cases.

The Advisory Council, while welcoming the acceptance by the Government of the recent proposals of the Burnham Committee, which would give increases of up to £200 per annum for senior masters, does not commit itself as to the adequacy of the proposals, beyond observing that their effect on the recruitment of science teachers should be carefully watched. The Council considers salaries to be of great importance, though this factor has its limits, and will scarcely influence either those with a definite vocation for teaching or those unprepared to consider teaching in any circumstances. Nor is its effect on others likely to be so great as that of the teacher himself on a pupil considering a career, or a widespread and imaginatively conducted campaign to influence public opinion.

For like reasons, deferment of National Service is likely to have but a limited effect in increasing the number of science graduates who take up teaching. The Advisory Council supports the recommendation of the Appleton Committee and of that appointed by the Federation of British Industries, and the Minister of Labour has since announced, on July 28, the indefinite deferment of first-class or second-class honours graduates in science and mathematics who take up teaching in a school maintained or aided by public funds. This is estimated as likely to give a further fifty or more science teachers a year, and is to be welcomed for that reason and as impressing on the country the serious national importance of the problem. It is unlikely, however, to influence many to take up teaching as a career; science graduates already have many other opportunities of finding work the national importance of which carries exemption from National Service in the military sense.

The argument for deferment derives its strength from the lessened risk of waste of man-power that it at least implies, and while the Advisory Council rightly gives no countenance to the suggestion from the Ministry of Education that over the next few years government departments and industry could reduce their recruitment of science graduates so as to increase the size of the pool from which the schools draw their science teachers, it recognizes the importance of seeing that the services of science graduates are fully and appropriately used. The suggestion runs counter, at least in the short-term, to current trends and accepted policy; for example, to the expansion of postgraduate scientific and technological education. The Advisory Council leaves industry to speak for itself in the matter, merely remarking that in general the industries of Britain are under-manned scientifically and that if industry temporarily relaxed its pressure for traine scientists it should do so only in the interests of t scientific man-power problem as a whole, and on t understanding that to do so would assure a great supply of scientists in the future.

So far as official bodies are concerned, the Advisor Council sees little possibility of any reduction in t recruitment of science graduates. It puts the numb of science graduates employed in government an allied research establishments (including the Atom Energy Authority, the research councils, the researc associations of the Department of Scientific an Industrial Research and the Service Department but excluding Service personnel) as less than 10,00 This is about half the number of graduate teache of science (including teachers at technical college and in Scottish schools, but excluding independe schools and the universities). The expansion government scientific staffs has for some time bee strictly limited, and established posts are mostly onl just sufficient to meet the responsibilities of th departments and research organizations concerne The Armed Forces may be an exception, and th Council recommends that their requirements first- and second-class honours graduates for certai posts in the Active Forces should be reviewe to see whether the qualifications demanded a justified.

That recommendation could well be more widel applied, and to a point at which it impinges eve more directly on educational policy. While in bot government departments and in industry publi policy would benefit by the wider use of men an women with scientific training and outlook i administrative positions, that should neither impl not exclude possession of a degree in science. Som economy in the use of science graduates might b secured by the use of graduates in arts, for exampl in posts where no special scientific knowledge required. This would be increasingly possible educational policy ensured that in this modern ag every university graduate acquired some unde standing of the method and achievements science.

The corollary of such recommendations, howeve is a fuller inquiry into the man-power situation. Th Advisory Council makes no reference to the impl cations, for that situation, of the development nuclear energy, of the Government's programmes f the development of rail and road transport, or of th deficiencies of some of the nationalized industries regard to research and the use of trained scientist and technologists. The figures quoted need to be s in the context of the present figures for industry including the nationalized industries as a whol having in mind the under-manning to which th Council refers, and in the light of the intake whic would be required to maintain the employment scientists and technologists even at its presen level.

The Advisory Council also considered a suggestio that the pool from which science teachers are draw might, as a short-term measure, be increased b reducing the number of science graduates who ar cepted for university postgraduate courses. Acadic leaders have in fact on other grounds questioned e desirability of accepting as postgraduate research udents those who do not show clear promise of ility as research workers, and of making postaduate research the exception rather than the rmal rule for an honours graduate. The Advisory ouncil estimates that out of 5,500 first-degree aduates in pure science (including some 500 overas students), about 1,500 men are deferred annually om military service for further university study, of hom some 250 are registered for teachers' training urses. More than half these appear to be working r a higher degree, and about one in three of first-gree science students stay on at the university for n additional two or three years. Of these, some )0 possess awards from a research council granted nder a very rigorous system of selection, and the inistry of Education works to similar standards in nsidering applications for the extension of State holarships. It is not certain, however, that the me standards are invariably applied to students ho are supported by other sources. The Advisory ouncil suggests that if the universities are not pplying over the whole field of graduate science aining the rigorous standards which now govern e postgraduate awards of the research councils and he Ministry of Education, they should be asked to onsider doing so. The Council has already asked the niversity Grants Committee to collect information s to the academic standards of those holding postraduate awards in science.

This is a sound suggestion. It will not, nor is it tended to, reduce the volume of worth-while postraduate research; though it may well eliminate ome of the more futile essays in that field. Nor will make available to the schools the best of the science raduates, or even increase the immediate supply of raduates, since those no longer deferred as research tudents would be liable for immediate National ervice. Their National Service over, however, they ould be seeking posts when the shortage of science eachers is expected to be even more acute, and some t least might become teachers.

This, like most other measures suggested by the dvisory Council, is a short-term measure. As long-erm measures the Council looks to an increase in those eading science at the universities sufficient to meet he needs of all fields of employment, though it uggests that reduction of early specialization in the chools and encouragement at the universities of the tudy of science as part of a general university ducation would greatly help. Inquiries are already n progress, it is stated, into ways of producing non-pecialist graduates with a broad training in science, ho would be suitable for various posts in industry nd the government service, and who would also be ompetent to teach science and mathematics in the chools.

There is another aspect of the man-power situation which is emphasized by the Advisory Council in this eport, and that is in relation to the inadequate olume of research on Colonial problems. Further iscussions with the Colonial Office have confirmed the Advisory Council in its view that the total volume of research in the Colonies is far too small. Only some 450 scientists are at present engaged in Colonial research—little more than one-tenth of the number of scientists employed in the United Kingdom by the Department of Scientific and Industrial Research and the research councils—and of these, less than a hundred are members of the Colonial Research Service. The Advisory Council recognizes that in present circumstances it is difficult to increase the number engaged in this work rapidly, but it expresses the firm opinion that everything possible should be done to increase the man-power available and ensure its better distribution. Pointedly, it expresses the hope that further developments will not be hindered by lack of adequate financial support.

That is a matter to which the Government should be giving attention, though it was not raised in the debate on the Colonial territories in the House of Lords on July 6, nor did Lord Lloyd refer to research in his reply for the Government. The Advisory Council emphasizes the urgent need for more research on long-term problems, such as population trends and food supplies, and reiterates the view as to the need for more plant geneticists and soil scientists in particular. Moreover, while the initiative for starting Colonial research projects generally rests with the Colonial territories themselves, scientific resources are likely to become even more stretched as social and political development quickens and local resources for long-term research may diminish. In this connexion, the Inter-University Council for Higher Education Overseas has pointed out that the development of the Colonial universities has transformed the position of science and scholarship within the Colonies and greatly encouraged research.

That there will thus be need for greater initiative to be taken in London in suggesting subjects for long-term research may be no bad thing, if the arrangements for concerting Colonial research policy are improved and the defects in organization which recent reports on Colonial research seem to suggest are overcome. It would fit in with the general observation which the Advisory Council makes in respect of the Seaweed Research Institute and, in view of the contribution which the Department of Scientific and Industrial Research is already making in certain fields of Colonial research, it may be hoped the committee now investigating the work of the Department will not overlook the possibilities in this respect. Sir Alexander Todd's membership of the committee, in view of his observations on this subject to the Parliamentary and Scientific Committee on July 12, certainly warrants this hope.

Meanwhile, it may be noted that the observations of the Inter-University Council fully endorse all the Advisory Council's remarks on the importance of looking on Colonial research as one special aspect of Britain's research effort and organization. The encouraging picture which the Inter-University Council depicts of expanding research stations and organizations in the Colonial territories, and of scientists in direct and continuous contact with local problems and opportunities who are accumulating a valuable body of local experience which they are linking with the world of organized learning, should not disguise the dependence of this man-power on institutions which are themselves largely fed from Great Britain—and often directly from British institutions. Apart from the fact that it will be a long time before most of the Colonial universities develop strong postgraduate schools from among their own students, the wise deployment of British scientific resources demands that Colonial research be considered as part of the wider problem. The suggestions made by the Inter-University Council for an increasing flow to the Colonial universities of research students and academic staff on sabbatical leave to use the facilities and opportunities now available, like the Advisory Council's proposal for the creation of pools of scientists in all the main fields of Colonial research, should be considered in this context. The latter proposal in particular, which might permit a British institution to send a senior man from its own staff for a few months to start a project, leaving it to the local staff to complete, seems well calculated to secure economy of man-power for many Colonial problems.

The Advisory Council's observations on this point, and particularly its plea for further assistance to the science departments in the new Colonial universities, and for the extension of home-based pools of scientists as indicated above, have a vital bearing on economy of man-power, and also on the efficient use and administration of Colonial Development and Welfare Funds and on educational policy—including the expansion of Colonial universities and university colleges and of higher technological institutes. The same consideration of economy in man-power has determined the Advisory Council's fresh reference to the proposals for a national reference library of science and invention and a national science lending library as part of the proposed 'science centre'. Both schemes are regarded by the Advisory Council as important if not essential for the efficient use of our existing scientific and technical man-power. Both are urgent, and the Advisory Council cannot see practical alternatives to either scheme. Disregard by the Government of the Advisory Council's renewed plea for firm decisions in favour of an early start for both these national library projects as part of a policy of equipping the nation with adequate scientific and technical library facilities can only mean a complete failure to appreciate the over-riding necessity for a concerted policy in education, research and development in order that the scientific and technical resources of Britain may be wisely and fully used.

That is the outstanding impression to be derived from the eighth annual report of the Advisory Council on Scientific Policy, and it was brought out even more emphatically by Sir Alexander Todd in the address to the Parliamentary and Scientific Committee already noted. In that address Sir Alexander estimated the total number of graduate scientists and engineers in the United Kingdom as 0·9 per cent of the working population, compared with 0·5 per
cent in 1939, but with United States figures
0·9 per cent in 1939 and 1·7 per cent in 1950; a
he gave the distribution of 78,000 graduates
mathematics and science in Great Britain as 12 p
cent in Civil Service and allied establishment
25 per cent as teachers in grant-aided schools a
technical colleges; 3 per cent in universities; a
60 per cent, including perhaps 2·5 per cent
independent schools, otherwise employed. He al
said that present shortages of scientists are mo
serious among physicists, chemists, metallurgists a
engineers, and that the demand for graduates
the engineering industry exceeds supply by abo
one-third. Sir Alexander added much more
indicate the lines on which educational policy shou
be shaped to deal with the situation as a whole; b
although his address was freely quoted in the House
Commons on July 21, and Mr. A. H. Albu in particul
quoted further estimates of the need, as distinct fro
the demand, for qualified engineers and scientist
apart from Mr. Albu's suggestion that a compr
hensive review of the situation and the actio
required to meet our rapidly changing needs shou
be the responsibility of one senior Minister, the
was no hint in the debate of the importance
urgent action at a high level. Indeed, the Minist
of Education, Sir David Eccles, agreed with mu
that Mr. Albu had said as to the shortage of scientis
and technicians, and made some wise comments
to the importance of general education and a sen
of values; he also promised a full statement befo
Christmas as to the Government's plans for shapin
the educational system of Britain so as to provide a
alternative and much more broader route than th
leading to a university degree for providing the ve
large number of technicians required to support th
technologists and scientists. Nevertheless, Sir Dav
appeared to be concerned at present chiefly to defe
the dubious decision to institute a new award
technology. Moreover, in declining to include in h
review of technological education the work of th
Royal Technical College, Glasgow, he demonstrat
again the departmental limitations and piecem
approach which have consistently marred th
handling of these and related problems by the prese
Government as well as by its predecessor. There a
indeed sound objections to a Ministry of Scienc
but such proposals will continue to be pressed un
clear evidence is forthcoming that the significance
science and technology in the affairs of State
fully appreciated by the Government, that d
weight is given to them in determining education
economic and defence policy, and that department
prejudices are not allowed to overrule the recon
mendations of the Government's scientific a
technical advisers.

The Advisory Council's report at least leaves
room for doubt as to the urgency or magnitude
the present problems, or that some very considerab
administrative changes are required if belated an
inadequate measures are no longer to waste o
limited existing resources and delay the develo
ment or creation of fresh supplies of man-power
energy.

## THAT INWARD EYE

e Mind and the Eye
Study of the Biologist's Standpoint. By Dr. Agnes
ber. Pp. xi+146. (Cambridge: At the University
ess, 1954.) 16s. net.

HIS review should begin with an apology to the
author of "The Mind and the Eye". Her book
s in the reviewer's hands some months ago; but
cumstances at the time made it impossible to give
the leisurely scrutiny it deserves. Perhaps this
lay has its advantages, for there is now an oppor-
nity to assess the value of the book a little at a
stance, in a better perspective than is generally
orded to a reviewer.

There is something very depressing about con-
nporary biological journals. Paper after paper
ords observations or experiments, analyses them
utiously, and in a timid and tentative way com-
res them with previous observations and experi-
nts on the same theme. That is about all: only
ely does the writer of a research paper disclose to
reader precisely what led him to do the work,
d only rarely does the writer disclose how (in his
w) his work is related to the broad panorama of
logy. There are doubtless sufficient reasons for
se omissions: many writers of papers undertake
research they describe for no other reason than
t their supervisors have 'put them on to it', and
ny editors of journals consider contemplation out
place in science and do not encourage authors to
lulge in it. The result is that apart from a few
orous growing points, the proliferation of bio-
ical research appears to an observer to be formless,
co-ordinated, and to some extent superfluous or at
y rate untimely.

In this perspective, Mrs. Arber's book stands out
a work of genuine scholarship and special time-
ess. It ought to be prescribed reading for every
sh graduate who proposes to begin research, and
ought to be read again by every young research
rker before he sends his first paper to the press.
s. Arber begins by a lucid description of the five
niliar stages of scientific investigation: the
mulation of a problem (a stage sometimes omitted),
collection of data, the interpretation of the data,
testing of the interpretation, and the com-
nication of the results to the scientific world. She
important things to say about all these stages,
l she embellishes her discussion by reference to
losophy and literature and art. How refreshing it
for example, to hear that the choice of a subject
research involves "the art of rejection", and to
told that this art can be compared with the art
the Chinese in designing the empty spaces in their
tures. It is refreshing, too, to be reminded (and
many research students it is to be told for the
t time) that the very observations one makes,
l *a fortiori* one's interpretation of them, are limited
the *Zeitgeist* and by unconscious philosophical
umptions derived from Spinoza.

If only biologists would study Mrs. Arber's chapter
writing up the results of research some of the
*laise* of our research journals might be cured.
nmunication is an essential part of research.
here is no escape," Mrs. Arber says, "from the
npulsive truths that the biologist must write, that
ting is an art, and, moreover, a highly symbolic
." It would be well if these words were frequently
oted in universities, for we are still in the state of mind that we willingly spend a year perfecting a technique, but we are unwilling to spend a week writing the paragraph describing the technique; and so the accuracy of experimentation may be blurred by clumsy communication. In this excellent chapter Mrs. Arber falters (in the reviewer's opinion) only twice: once when she implies that the quality of writing in research papers can be too good, because sensitive idiomatic English is harder to translate into foreign languages than poor writing is; and once when she confuses lucidity with over-simplification, and goes on to make the dubious assertion that the opaque passages in a piece of writing "keep the reader awake". These seem poor excuses for taking the edge off the precision of one's instrument. Cyclotrons and electron microscopes notwithstanding, language remains the chief instrument of the scientist.

Having dealt elegantly and convincingly with these five stages of scientific investigation, Mrs. Arber comes to the main theme of her book, namely, that there is a sixth stage: contemplation, meditation, reflexion on the methods and assumptions and implications of scientific research. With a wealth of reading and contemplation behind her, Mrs. Arber discusses the concept of truth in biology (the subtle difference between *Richtigkeit* and *Wahrheit*); she admits that a biologist cannot be an expert on his philosophical assumptions or on his microscope, but she asserts that he ought to have given thought to both these instruments; she doubts (and the reviewer would join issue with her here) whether Occam's razor is as efficacious in biology as in the physical sciences; and she has very sensible things to say about antitheses in biology: matter and form, form and function, mechanism and teleology. Her last antithesis is the mind and the eye. Is one to agree with Coleridge, who thought it necessary "to emancipate the mind from the despotism of the eye" as a condition of abstract thought? Or does the eye provide the yarn out of which the mind weaves abstract thought? Mrs. Arber subscribes to the view that mental activity and sense impressions are inseparable and that the eye is junior partner to the mind.

This book is an example of scientific criticism worthy to stand beside the best literary criticism of our time. Is it too much to hope that working biologists will take it seriously? If they do, we might expect a notable improvement in the quality of scientific writing.

ERIC ASHBY

## LINEARIZED AERODYNAMICS

Linearized Theory of Steady High-Speed Flow
By Prof. G. N. Ward. (Cambridge Monographs on Mechanics and Applied Mathematics.) Pp. xv+243. (Cambridge: At the University Press, 1955.) 30s. net.

FOR some years, research workers in theoretical aerodynamics have been greatly indebted to Prof. G. N. Ward for the fine series of papers in which he has made a number of fundamental and important contributions to the linearized theory of steady high-speed flow, and they will welcome the appearance of this volume in which the author's researches are expounded in magisterial fashion. The volume is, in fact, a revised and shortened version of an essay submitted in competition for the Adams Prize in the University of Cambridge. Its publication in a certain sense marks the end of an epoch, for the linearized theory has reached the stage of completion, in the sense that it is now possible to formulate and to solve almost all the problems which can be usefully tackled by means of this theory. Further advances inevitably and reluctantly will almost certainly be made by means of non-linear theories.

It is well known that the essence of the linearized theory consists in retaining only those terms which are of the first degree in the disturbance velocities, the pressure excess and the density variation which are produced by the passage of an aircraft or a missile through still air. The enormous advantage of the linearized theory is that it is possible to bring to bear all the methods of classical mathematical physics and, in particular, the powerful methods of potential theory and of wave theory. What makes the subject particularly exciting is that in the supersonic range all the concepts and methods of classical potential theory need considerable revision, and that progress is scarcely possible without employing some mathematical methods equivalent to Hadamard's theory of the finite part of divergent integrals. The use of Heaviside transforms and Fourier integrals can also be employed with great effect. The present volume gives a complete and self-contained account of all the mathematical techniques which are required in the solution of linearized equations and, in particular, of the important integral identities discovered by the author in collaboration with F. Ursell.

After an introductory chapter which carefully analyses all the assumptions involved in the linearization of the equations of motion, the author proceeds to discuss in the two following chapters the general solution of these equations for subsonic flow and for supersonic flow. He then gives a number of corollaries related to the boundary conditions, aerodynamic forces, uniqueness of solution and the interesting flow reversal theories.

The second part of this work is concerned with a number of special methods. First, the subsonic flow past thin bodies is discussed with special reference to the developments of the Prandtl–Glauert rule.

Then the author discusses supersonic flow past nearly plane wings. Here the pioneer work of Evvard is extended so that these problems are reduced to the solution of a number of integral equations of Abel's type. This is followed by a study of conical fields in supersonic flow which follows admirably the exposition given by the author and Prof. S. Goldstein. A whole chapter is then devoted to the application of operational methods, with special reference to the flow past quasi-cylindrical ducts and to axially symmetric free jets.

The final section of this work is concerned with the slender-body theory. First of all, the author summarizes the familiar results for the flow past bodies of revolution, and then discusses the generalization of these results to bodies with arbitrary cross-sections. Here the results are obtained by direct solution of the wave equation and not by the operational methods by which they were originally discovered. To many readers the direct solution of the wave equation will seem to be a distinct advance. These methods are then applied to winged bodies of revolution, giving the effects of wing-body interference.

There can be no doubt that the present volume is a most welcome addition to the series of Cambridge monographs and that it will long continue to have a permanent value as an authoritative account of t linearized theory of steady high-speed flow. ] mathematical difficulties are overlooked, and t physical significance of the mathematical equatio is always kept well in mind. Perhaps some read will put down this volume with a certain sadness— deals so completely with the linearized theory th nothing seems to be left to be attempted by resear workers but a few special problems and the gre challenge of second-order theories and the full no linear equations of compressible flow.

G. TEMPLE

# RESEARCH AT HARWELL

### Atomic Energy Research at Harwell

By K. E. B. Jay. Pp. xii+144+19 plates. (Londo Butterworths Scientific Publications, 1955.) 5s.

As stated in the introduction to the book, th report carries forward the story of the Atom Energy Research Establishment, Harwell, from th point at which it was left in a previous publicatio and also contains some material which, either f reasons of secrecy or lack of space, could not l included in the first account. It is divided into tw parts: the first, written primarily for the no technical reader, deals with the major programm of the Establishment, while the second, for th scientific reader, attempts to treat in more det certain selected aspects of research at Harwell.

If one compares the two parts of the volume, appears that Part 2 rather misses its target. T difficulty of giving in sufficient detail, in such a sho space, an account of the many interesting fund mental researches being carried out at Harwell well-nigh insurmountable, and it might have be better to give a more general description togeth with a list of topics and the appropriate references the published literature.

Part 1, on the other hand, contains a very inte esting and readable account of the major programm in applied research. Beginning with a brief explan tion of the relation between Harwell and the Indu trial Group[2], there follows an excellent account of th progress made in reactor design and of the problem remaining to be solved if electrical power is to produced economically from nuclear energy. Chapt 3 gives a clear picture of the increasing use of radi active isotopes in medicine, research and industr and of the large part played by Harwell in th process. There follow chapters devoted to oth aspects of work at Harwell, to the relations betwe the Establishment and British universities and oth research institutions, while last, and by no mea least, an outline is given of some of the human a administrative problems involved in the running an organization of this size. In addition to diagra where necessary, there is a number of excelle photographs.

The author has contrived to give, in a short spa a good account of what goes on at Harwell, and th publishers are to be congratulated on producing th volume at such a low price. To those who, like t reviewer, believe in getting value for their mone this volume may be safely recommended.

P. J. GRANT

# HIGH-ENERGY NUCLEAR PHYSICS

## PHYSICAL SOCIETY'S SUMMER MEETING

HERE are now three machines in Great Britain which can produce π-mesons in useful numbers. ese are the 1,000-MeV. proton synchrotron at mingham, the 400-MeV. synchro-cyclotron at erpool and the 300-MeV. electron synchrotron at ısgow. All three accelerators have been in suc- sful operation for some time, and the first experi- ntal results are beginning to appear. It was refore timely for the Physical Society to devote whole of its provincial summer meeting, held ring July 5–6, to high-energy nuclear physics. e choice of Liverpool as a meeting place was ticularly appropriate in view of the striking ccess recently achieved there in the extraction of beam from the synchro-cyclotron. Members of Society and visitors had an opportunity during meeting of visiting the Nuclear Research Labor- ry of the University, where, in addition to the -MeV. synchro-cyclotron, a 37-in. cyclotron and -MeV. high-tension accelerator are also in oper- on. The average attendance at the meetings was ut 150, and some seventy members joined in the ference dinner held in the University Staff House July 5.

he scientific programme was preceded by a short iness meeting, during which the president of the ysical Society (Prof. H. S. W. Massey) expressed pleasure at the opportunity offered to the Society visiting Liverpool. In reply to this, Prof. H. W. B. nner welcomed the Society, and in particular a nber of overseas visitors, to what was possibly first conference on work with high-energy chines outside the United States. The subsequent ers and discussions left little doubt that high- rgy physics is now a flourishing subject in Great tain. It was particularly interesting to note that high-energy accelerators are being used by ups of workers from many laboratories, and that laboration of this sort is likely to increase. In the sent report, only the names of those actually senting the papers are given, although those of ir co-workers were in general scrupulously ounced at the meeting.

he papers presented on the first day were all cerned with the interaction of high-energy trons and protons with matter. Several papers cribed work carried out at Harwell, where the -MeV. synchro-cyclotron, although not useful for eson production, was the first high-energy elerator to start working in Britain, and has been d for a large number of precise experiments in high-energy field. T. C. Randle (Atomic Energy earch Establishment, Harwell) described a new ermination of the angular distribution in $(n,p)$ ttering at 130 MeV., which clearly shows a marked mmetry between backward and forward scatter- . T. C. Griffith (University College, London) later cribed another determination of the differential s-section for $(n,p)$ scattering using the neutron m of the Harwell cyclotron with photographic- lsion recording of the recoil protons. His results er the angular range 57½–82½° in the laboratory tem and agree with those of other workers within limits of error. Some observations of the charged ticles emitted by carbon under neutron bombardment were obtained in the course of this work. P. Hillman (Harwell) reported on the observation of polarization in the scattering of 100-MeV. neutrons by free protons. This is an extremely difficult experiment, but good evidence for a real effect was presented, and the chairman (Prof. H. S. W. Massey) emphasized its importance for a proper analysis of nucleon-scattering work. Another interesting and informative experiment of a similar nature using the 100-MeV. neutrons from the Harwell machine was described by R. Wilson (Oxford). He and his colleagues have been able to observe the Coulomb scattering of neutrons, due to the motion of the neutron magnetic moment in the electric field of the nucleus. This scattering was predicted by Schwinger and is observable only at forward angles of less than 1°. In this region, interference between the Coulomb and nuclear scattering gives a polarization effect and enables the polarization of the initial neutron beam to be demonstrated. J. M. Dickson (Harwell) described polarization effects observed at angles between 3° and 20° in the scattering of polarized protons by carbon, aluminium, copper and silver. The effect of the interference between Coulomb and nuclear scattering in the asymmetry was very clearly shown. Both the $(p,p)$ and the $(n,p)$ experiments were remarkable for the angular precision achieved. Later in the meeting, A. Roberts (Rochester, U.S.A., and U.S. Office of Naval Research, London) reported on earlier $(n,p)$ polarization experiments at Rochester which are in agreement with the Harwell results, and cover a wider energy range. He also described $(p,p)$ polarization work and showed how the polarization produced in the scattering of protons by carbon is zero near the first diffraction minimum.

L. Riddiford (Birmingham) described the results of a study of the $(p,p)$ interaction at about 650 MeV. using protons accelerated in the Birmingham synchrotron. At this energy the differential cross-section for elastic scattering may be influenced by the possibility of meson production, and a forward peak might be expected, in contrast with the isotropic distribution obtained at lower energies. The results for 131 events, which were obtained with a diffusion cloud chamber filled with hydrogen to a pressure of 25 atmospheres and operating in a magnetic field of 13 k.gauss show this feature. Of the inelastic events in hydrogen, forty-five examples of $\pi^+$-meson production and nine examples of $\pi^0$-meson production were identified. Angular correlation measurements made for the cases of $\pi^+$-meson production were in agreement with the hypothesis of an excited state of the nucleon–meson system corresponding to the $T = 3/2$ resonance observed in meson–nucleon scattering. W. O. Lock (Birmingham) reported on a similar study using 950-MeV. protons from the Birmingham machine. Collisions with hydrogen were obtained and recorded in nuclear emulsions, and the events were studied independently at Birmingham, Belfast and Glasgow. In this work a marked deviation from isotropy was also seen at forward angles, including a dip near 0°, which may still be due to poor statistics. The experiment gives a cross-section for $(p,p)$ elastic scattering at 950 MeV. of 15·5 ± 3 mb.; no evidence for appreciable polarization of the beam scattered out of the synchrotron at 4° was found. In the same exposures 'quasi-elastic' collisions of the incident proton with bound protons in the heavier nuclei of the emulsion are recorded, and identification and analysis of these events was described by W. M. Gibson (Belfast).

Some discussion took place on the effort spent in analysing experiments made with photographic plates and diffusion cloud chambers. The great experimental advantages conferred by the availability of a continuous, intense and homogeneous external beam were clearly brought out in a paper by J. R. Holt (Liverpool) on the elastic scattering of protons by hydrogen at 380 MeV. The differential cross-section at 90° was found by coincidence counting using the carbon–polythene difference method; and a result of 3·63 millibarns, with an accuracy of about 1 per cent, was obtained. The excellent conditions available at Liverpool for precision high-energy experiments in the 400 MeV. region were well shown in this work. Another example of the type of work now possible at Liverpool was given by A. Ashmore, who presented the results of measurements of neutron total cross-sections for a number of elements using the transmission method with a scintillation telescope.

Towards the end of the first day, Prof. Massey reviewed progress in high-energy scattering and polarization phenomena, referring in particular to the very precise work which has now been reported from the 660-MeV. Moscow synchro-cyclotron. He stressed the fact that advances in experimental technique have been extremely rapid, and that it is now possible to envisage triple- and quadruple-scattering experiments which could determine uniquely the unknown parameters in the general nucleon–nucleon scattering matrix.

The second day of the meeting was devoted to miscellaneous topics. The Glasgow electron synchrotron was described by W. Macfarlane; it now produces 4 × $10^{10}$ equivalent quanta per min. for a pulse-rate of 5 per sec. and an energy of 340 MeV., which appears to be better than the performance of comparable American machines. The beam has been collimated to ¼ in. diameter at 125 cm. from the synchrotron. Arrangements for monitoring the beam with a pair spectrometer were described and some excellent expansion-chamber pictures of photon-induced stars in air were shown. The Glasgow synchrotron will be used in part for a study of the photoproduction of π-mesons, and E. H. Bellamy reported preliminary observations on the ratio of $\pi^+$- to $\pi^-$-mesons produced in calcium; nuclear emulsion detectors were used, and the ratio was found for three energy ranges. R. G. Moorhouse (Glasgow) reported on new calculations on the photoproduction of mesons, referring in particular to the effect of *E2* transitions on the angular distribution of mesons.

Several papers were devoted to the properties of π-mesons. S. W. Barnes (Rochester, U.S.A.) described measurements of the absolute differential cross-section for the elastic scattering of $\pi^+$-mesons by protons at centre-of-mass angles of 43° and 90°. The meson energy was 43 MeV. and a liquid hydrogen target was used, with ring-shaped crystals to define and detect the scattered mesons. By combining the two measurements with an earlier and less accurate determination at 180°, the following values for the *s*- and *p*-wave phase-shifts in the isotopic spin state $T = 3/2$ for a meson energy of 43 MeV. were obtained: $\alpha_3 = -4\cdot3°$; $\alpha_{33} = +4\cdot4°$; $\alpha_{31} = -1\cdot35°$. Roberts (Rochester, U.S.A.) in a later paper poin out that in a scattering experiment the effects π-mesons in more than one state of orbital mot with respect to the scattering centre are usua superimposed. In a $\pi^-$-mesonic atom, however, which a $\pi^-$-meson exists for a finite time in a B orbit about the central nucleus, pure states of orbi motion exist. The electromagnetic transitions in su an atom thus directly relate the energies of sta such as 1*s*, 2*p*, 2*s*, 3*p*. The Coulomb energies of th states can be calculated very accurately, and nuclear shift of the energy-levels can then be dedu from experimental observation of the mesonic X-ra Dr. Roberts described an accurate determination the 2*p* – 1*s* transition energy ($K_\alpha$ and $K_\beta$) in mesonic *K*-series of oxygen; 40-MeV. $\pi^-$-mes were brought to rest in oxygen, and the X-rays, energy 164 ± 4 keV., were detected in a sodi iodide crystal. An upward nuclear shift of the level was established, showing that there is repuls in the *s*-state of motion between a meson and nucleus. The nuclear shift has also been determi for other atoms by workers at the Carnegie Institu Pittsburgh; unfortunately, it has not yet b possible to measure it for hydrogen. Some sim observations of the 2*p* – 1*s* transition energy μ-mesonic atoms were reported by F. D. S. Butem (Harwell), whose work was carried out using μ-mes produced by the decay of π-mesons from the Liv pool cyclotron. For copper a value of 1·55 MeV. v obtained for the unresolved doublet and for l 5·84 MeV. These values agree with the earlier w of Fitch and Rainwater and lead to the expressi $R = 1\cdot19 \times 10^{-13} A^{1/3}$ for the electromagnetic rad of a nucleus of mass number *A*.

J. M. Cassels (Liverpool) spoke on total cro section measurements with positive and negat π-mesons from the Liverpool cyclotron. It is ho soon to exploit the intense external beam of machine as a source of high-energy $\pi^+$-mesons, wh are usually difficult to extract from orbital accel ators; but in this work an internal target and same channel (with reversed cyclotron fields) w used for both $\pi^+$- and $\pi^-$-mesons. The meson ene was 85 MeV., and total cross-sections were found the transmission method using a scintillation coun telescope. Observations of the loss cross-section w made with different angles of acceptance for the fi crystal, so that the loss due to Coulomb and diffract scattering (counted as elastic processes) could distinguished from that due to nuclear absorpt (counted as inelastic processes). The results presen were:

| Nucleus | Absorption cross-section (millibarns) $\pi^-$ | $\pi^+$ | Error (per cen |
|---|---|---|---|
| Carbon | 367 | 283 | 8 |
| Aluminium | 684 | 563 | |
| Copper | 1,420 | 960 | |
| Cadmium | 2,190 | 1,440 | |
| Lead | 3,400 | 2,280 | 5 |

The difference between the $\pi^+$- and $\pi^-$-absorp cross-sections for the heavier nuclei may be explai by a simple Coulomb effect, but this is not adequ to interpret the results for carbon. The nuc radius for lead deduced from the observed cr sections is 95 × $10^{-13}$ cm., compared with a valu 7·2 × $10^{-13}$ cm. estimated otherwise, so that the l

cleus appears completely black to both types of
arged π-meson at an energy of 85 MeV.

Some details of the interaction of high-energy
otons with complex nuclei were presented by
rkers from Birmingham. W. E. Burcham and J. L.
monds described a measurement of the absolute
ss-section for the $^{12}C(p,pn)^{11}C$ reaction with proton
ergies between 250 and 950 MeV. The cross-section
carbon-11 production falls off slowly over this
ergy-range to a value of 20·5 ± 1·1 millibarns
950 MeV. The ratio of sodium-24 and fluorine-18
ivities from aluminium bombarded by high-energy
otons to carbon-11 activity from polythene bom-
rded by the same protons was also found for the
ne range of energies using the internal beam of the
rmingham synchrotron. D. L. Anderson described
pecial type of photographic emulsion camera which
s been installed in the vacuum system of the
rmingham machine. The magnetic field of the
chine was used for resolution, and the energy
tribution of protons scattered inelastically from
bon was obtained. For low proton energies the
ults are consistent with a Gaussian distribution of
ernal momentum in the carbon nucleus.

The day's proceedings included two technical
pers of particular interest. K. J. Le Couteur
verpool) described the calculations which he had
de on the Tuck–Teng system of beam extraction.
ese calculations were the basis of the design of the
ler and regenerator fields installed in the Liverpool
lotron. When tried, it was found that the system
aved as anticipated, and that it was possible to
ft the circulating beam laterally a large distance
one turn. About one-fifth of the circulating beam
s made to enter a magnetic channel and 3 per
t of the internal beam, with an energy of 380 ±
MeV., was obtained at the end of the channel.
ter concentration with a focusing magnet, 2 per
t of the internal beam was measured on a target
about 1 in. diameter at a distance of 40 ft. from
cyclotron. The resulting flux of 4 × $10^{10}$ protons
cm.$^2$ per sec. is about a thousand times better
n has been obtained on other machines, and has
n a major contribution to the efficient utilization
existing high-energy accelerators. The accelerators
the future must, however, reach much higher
rgies than any at present attained, and the
velopment of new ideas in this subject was reviewed
W. Walkinshaw (Harwell). The application of
principle of alternating-gradient focusing to
chrotron-type accelerators has been thoroughly
estigated and underlies the design of the 25-GeV.
chines now under construction at Geneva and at
okhaven. The great expense of these machines
, however, stimulated several groups to consider
rnative designs, and those proposed by the Mid-
stern Universities Research Association of the
ited States (*M.U.R.A.* group) were discussed in
ne detail. These envisage a magnet which is
ited by direct current and are described as *FFAG*
ed-field alternating-gradient) machines. Essen-
lly, fields of special shape are used to confine a
ge range of momentum within a small range of
ius. Typical design figures were presented. There
also the possibility of a fixed-field alternating-
dient constant-frequency cyclotron for an energy
perhaps 2 GeV. with a current of perhaps 100 micro-
peres. The remarkable possibilities for experiment
ned up by such designs make it essential to
nplete detailed studies of their practicability and
t as early as possible.

W. E. BURCHAM

# FOOD MICROBIOLOGY AND PUBLIC HEALTH

A ONE-AND-A-HALF day symposium on "Food Microbiology and Public Health" formed part of the summer conference organized by the Society for Applied Bacteriology, held in Cambridge during July 3–6. Sixteen papers were contributed by authorities in various aspects of the subject from different parts of the world, and the chairmen at the three sessions were the president of the Society, Mr. S. B. Thomas (Aberystwyth), Colonel H. J. Bensted (Colindale) and Dr. G. S. Wilson (London). Several of the contributors described individual outbreaks of bacterial food poisoning and traced so far as possible the likely sources of the trouble. The whole tone of the meeting was directed not to the dangers of food poisoning in itself, but to the dangers arising from ineffective processing, careless handling or unsatisfactory storage conditions.

The first section of the symposium dealt with milk and synthetic cream products, and K. W. Newell (Colindale) described an outbreak of infection in several families arising from eating chocolate éclairs. Fæcal coli and a few *Salmonella paratyphi* were found in the cake mixture and also in the mixing machine; but the principal contamination was *Salm. thompson*, traced to a single delivery of an unusual pack of Chinese frozen eggs, from which two other strains were also isolated, *pullorum* and *aberdeen*. Describing the method of sampling and of isolating the contaminants, Betty Hobbs and Muriel Smith (Colindale) considered that incubation in selenite medium followed by plating on Leifson medium containing 1 per cent of sucrose is the most satisfactory method. In reply to questions, Dr. Hobbs said that these organisms can survive for more than a year in the frozen state, and that *Salm. pullorum* cannot be used as an indicator organism, partly because no really satisfactory isolation media have yet been devised.

Custard was the next topic discussed, and R. M. Fry and Joan Boissard (Cambridge) described a sudden outbreak of sore throat, pyrexia and collapse in one section of an army camp following an evening meal which included this comestible. Most of the cases were reported within 48 hr. of taking the meal, and nearly all of the throat swabs yielded cultures of *Streptococcus pyogenes*, Type 9. The incidence of infection pointed to one cauldron of custard handled by one particular cook as the source of the trouble. Doubts were expressed at first concerning this finding, because the material had been handled hot; but it was shown in the laboratory that, although the bulk of material might be at a high temperature, the skin of the custard was relatively cool and so would allow survival of infected droplets falling on the surface.

Emphasis was placed on the importance of the correct handling of dried milk by H. B. Hawley and Margaret Benjamin (Yeovil), because growth of bacteria, and especially of staphylococci, can take place readily at certain stages of processing. They described the design of a suitable drying plant, and said that growth takes place particularly at the 'evaporated milk' stage. For this reason, regular daily cleaning of the plant is essential. The staphylococcal species in the dried milk are different from those in the original milk, pointing to human or air-borne contamination gaining access during processing. Coliforms die out quickly in the dried powder, but micrococci are relatively resistant. Betty Hobbs (Colindale) quoted eight outbreaks of staphylococcal food poisoning occurring during the summer of 1953, all of which were traced to 'cream' made with dried milk. Growth of staphylococci in the cream was relatively slow, hence the poisoning must have been due to the heat-resistant toxins remaining in the dried milk. Seven of the outbreaks were from milks processed by one manufacturer, and the infection was always found in batches made towards the end of each day, a point which underlines the importance of regular daily cleaning of plant.

In a paper on faecal bacteria occurring in citrus juices, Prof. M. D. Appleman (University of California) said that interest was aroused because of the increasing consumption of unpasteurized juices. Although the juices are at pH 4 (approximately), a number of types of micro-organism can survive, and even grow, to cause spoilage. High counts invariably mean that unsound fruits have been used or that they have been handled carelessly. Although coliforms occur with some frequency, faecal streptococci appear to be the best organisms for indicating general contamination. A recorded contribution from M. W. Wilson and E. F. Mackenzie (Melbourne) described first the methods used in the State of Victoria for identifying carriers and isolating cases, and then went on to discuss in detail several outbreaks, generally occurring in young persons, of *Salmonella* infections of the *senftenberg* type. All were traced to confections containing desiccated coconut supplied from Papua and distributed by two wholesalers in Victoria. Several *Salmonella* species were isolated, including *Salm. oranienburg*, *potsdam* and *senftenberg*, originating obviously from the ecological conditions obtaining in one factory in particular. In the subsequent discussion it was stated that the heat resistances of the different *Salmonella* types vary considerably. The query was also raised that, although a certain heat treatment may have been applied, what was the actual temperature attained by the particles, and what was the moisture content ?; these factors would affect the lethal efficiency of the heating.

In the section devoted to meats and fish, J. M. Shewan and J. Liston (Aberdeen) discussed food poisonings caused by fish. The normal bacterial flora are non-pathogenic, and generally fish is stored sufficiently cool to prevent undue bacterial growth; but occasional pathogens are found in fish living in polluted waters. Type *E* botulism occurs in fish taken near Continental ports, but it has not been found in British waters. Particularly susceptible is the mackerel–tunny group, and poisoning seems to be due to histidine being converted to histamine during ripening. Tropical fish are much more poisonous than temperate ones, the poisons usually being of the neurotoxin or histamine type. Turning to fresh meats, the conference heard a paper by H. Lundback (Stockholm) on two extensive *Salmonella* outbreaks occurring in 1953, one being due to *Salm. typhimurium*. This had its source in one slaughterhouse in southern Sweden from which pork meat was found to be more heavily infected than veal. It was not possible to determine on the evidence available whether the infection was of animal or human origin. Fifteen per cent of the staff were found to be carriers at one stage.

M. Ingram and Ella Barnes (Cambridge) reported that feeding antibiotics to animals may alter significantly the microbial flora found in the g
eliminating, for example, the streptococci and c
tridia, and this may improve the quality of cert
meats and reduce spoilage. This has been shown
be the case after feeding with aureomycin and t
less extent with neomycin. Only the yeasts
resistant, but this can be overcome. Dipping free
killed meat in an antibiotic solution improves
keeping quality. Although this method is of
doubted advantage, there remain the toxicity
the medico–legal aspects to be considered.

As might be expected, cooked meats are equa
if not more, susceptible to bacterial infection,
A. A. Miller and F. Ramsden (Preston) descri
two fairly large outbreaks of *Salmonella* infecti
occurring some two years ago from consuming m
pies. In both outbreaks, *Salm. morbificans* was
cause, the infections being of animal origin. S
sequent investigations showed that inadequate bak
was the reason for the spread of the infection ; it
also made clear that adequate precautions must
taken after baking to prevent the access of infecti
for example, when adding the gelatin filler.
Buttiaux and H. Beerens (Lille) discussed
incidence of gas-forming *Clostridia* in canned me
and found ninety such infections from 109 c
examined. *Cl. welchii* occurred most frequen
followed by *Cl. bifermentans*, and all originated fr
semi-preserved meats or processed meats inadequat
heated. Using a 'micro-ham' medium, recommen
for isolating the cultures, pH was found not to
significant in preventing growth ; 4 per cent of
was ineffective, but higher concentrations were ;
nitrite and nitrate were ineffective at 0·02 per c
and 0·1 per cent, respectively.

In the last section of the symposium, concern
with bacteria causing food poisoning, Prof. S. Ha
(Oslo) discussed the role of aerobic spore-form
Four outbreaks in Oslo were traced to *Bacillus cer*
occurring in dessert sauces. Although, in every ca
the infection was very high, it was not detec
organoleptically. The poisoning is not an infect
but an intoxication, and the symptoms are similar
*Cl. welchii* poisoning. According to Joan Tay
(Colindale), it is possible that some outbreaks may
due to mixed infections such as that of *Proteus*
*Bact. coli*. Coliforms themselves are not genera
pathogenic, but in this connexion the host may
important. In Britain they form 8 per cent of
cases of 'known cause'. Considering the colifo
group generally, special serological types of *Bact.*
have been identified with certain infections, and
the remaining organisms, *Ps. pyocyanea*, *Proteus*
the paracolons, the evidence against them is mai
circumstantial. B. Moore (Exeter) said that va
cases have been proved of food poisoning due
*Streptococcus faecalis*, of which there appear to be t
types, one with a short incubation period and o
with a longer one. In all cases a very heavy infect
is necessary to produce the symptoms, and fr
laboratory tests with experimental animals
medium and the age of the culture are important
determining toxicity. Type *E* botulism, first detec
in 1936, has been the cause of several outbreaks
the Continent ; it has never been detected in Brita
H. O. Pedersen (Frederiksberg) said that infection
associated exclusively with fish, the toxin be
produced only if the organism is incubated bel
37° C. The organism has been found in various s
and sea muds, particularly those in harbours, hen
the significance of fish in conveying infection. It l

rtain cultural peculiarities and the spores are readily led by mild heat.

The full papers of the symposium will appear in forthcoming issue of the *Journal of Applied cteriology*.

# ROTECTION AGAINST IONIZING RADIATIONS

[T]HE rapidly widening range of applications of atomic energy and artificial radioactivity and the creasing concern and speculation on the part of e general public concerning the biological effects of nizing radiations make the publication of the latest commendations of the International Commission on adiological Protection* an event of major importce. The Commission functions under the auspices the International Congress of Radiology, which ld its seventh meeting in Copenhagen in 1953.

The history of radiation protection extends back far as 1921, to the inauguration in the United ngdom of the British X-ray and Radium Protection mmittee working under the auspices of the British stitute of Radiology, and in the United States the Röntgen Ray Protection Committee. The rmation of these and other national committees led the first International Commission on Radiological otection in 1928. Since that time the Commission s met at regular intervals, and its expanding sphere interest may be judged by comparing the present -page report with the last recommendations issued, 1950, comprising some eight pages in print. The itish X-ray and Radium Protection Committee has cently handed over its responsibility to other mmittees meeting under the auspices of the inistry of Health and the Medical Research Council, d these bodies have set up a joint Radiological otection Service to advise users in the United ingdom on all matters relating to protection.

The present Commission includes members from n nations and has five sub-committees dealing spectively with the permissible dose for external diation, the permissible dose for internal radiation, otection against X-rays up to three million volts, otection against X-rays above three million volts d against heavy particles, and the disposal of dioactive wastes and handling of radioactive isopes. The report gives the recommendations of the st four of these; the report of the sub-committee the handling and disposal of radioactive materials ill be published later as an addendum.

In formulating its recommendations, the Commison recognizes that any significant departure from e environmental conditions in which man has olved may strictly entail some hazard. Since no diation-level above the natural background due to rrestrial radioactivity and cosmic rays is absolutely fe, the problem is to choose a practical level that volves a negligible risk. The concept invoked re is that of a "maximum permissible weekly dose" radiation or a "maximum permissible body burden" a radioisotope such that if exposure at this level ere continued indefinitely, no appreciable bodily jury would be expected to result during the lifetime the exposed individual. The recommendations are primarily intended to apply to the occupational exposure of personnel forming only a small fraction of the community, and in such circumstances genetic changes affecting the race as a whole are not considered the limiting factor. The report suggests a reduction of all permissible levels by a factor of 10 to take account of possible genetic effects where exposure of a large population is involved.

Past recommendations of the Commission have been chiefly concerned with the establishment of a maximum permissible weekly dose in rontgen units for whole-body exposure to X- or γ-radiation, and in 1950 this was fixed at 0·3 r./week. The sub-committee on the permissible dose for external radiation does not now recommend any change in this basic value for X- and γ-rays up to 3 MeV., which remains at 0·3 r./week, corresponding approximately to an absorbed dose in soft tissue of 0·3 rad/week. Maximum permissible levels for other types of ionizing radiation are also considered.

Some confusion may result from the multiplicity of units used in the report for the expression of radiation dose or radiation absorption in tissue. This arises in part from the fact that shortly before its publication the International Commission on Radiological Units recommended that the rad should be used wherever possible as the unit of absorbed radiation dose. This unit is equal to an energy absorption of 100 ergs/gram. Because of the varying biological effectiveness of different types of radiation, it is found necessary to introduce a further unit—the rem—which is defined on p. 19 as "the absorbed dose of any ionizing radiation which has the same biological effectiveness as 1 rad of X-radiation . . ." This appears to be at variance with previous definitions of the rem as that dose which has the same biological effectiveness as 1 rontgen of X-rays. The use of the rem might have been avoided had the Commission chosen to recommend that the maximum permissible dose for heavy ionizing particles should be that for X- or γ-rays divided by the relative biological effectiveness of the radiation in question. It must be pointed out that the relative biological effectiveness for any given radiation may depend on the type of biological effect studied.

On p. 17 it is assumed that the tissue dose in rads is approximately numerically equal to the dose in rontgens in the tissue concerned. It should perhaps be emphasized that this assumption is only valid in soft tissue where the mean atomic number is nearly equal to that of air. Some clarification of these issues would be welcome in future recommendations of the Commission.

Radiobiological studies have demonstrated that certain organs of the body—notably the skin, blood-forming organs, gonads and eyes—are particularly vulnerable to radiation damage. Special consideration is therefore necessary with highly non-uniform distributions of radiation dose such as may be encountered in exposure to particulate radiation. For this purpose, the concept of the 'critical organ' is introduced; by this is implied the organ of the body which under the conditions of the exposure receives the dose that results in the greatest bodily damage. The criterion used in establishing maximum permissible levels is that the dose absorbed by the critical organ shall not exceed 0·3 rad/week of X- or γ-rays or an equivalent amount of other radiation.

The idea of the 'critical organ' is fundamental to the report of the sub-committee on the permissible dose for internal radiation, which considers the hazards due to ingestion or inhalation of radioactive materials. Taking account of the non-uniform distribution of radioactive material in the body, maximum permissible levels of concentration in air and drinking water are quoted for ninety-one isotopes or mixtures of isotopes. For most of these, the criterion used is that of the absorbed dose in the critical organ, the calculations being based on a "standard man" in whom all characteristics are chosen to be those representative of the average man. In the case of α-emitting radioisotopes that become localized in bone, however, the levels are based on a direct comparison with radium. A large accumulation of human experience is available regarding the effects of ingested radium in man, and the maximum permissible body burden of this element has long been fixed at 0·1 μc.

---

* Recommendations of the International Commission on Radioical Protection (Revised December 1, 1954). British Journal of diology Supplement No. 6. Pp. x+92 (London: British Institute Radiology, 1955.) 10s. 6d. with paper cover, 12s. 6d. with cloth cover.

With many other isotopes, human data are usually completely lacking, and distribution and turnover must be estimated in other ways, for example, from the results of animal experiments. The sub-committee acknowledges that these calculations are often only approximate. Moreover, the figure of 0·3 rad/week applies properly to whole-body radiation, and its extension to partial-body irradiation of a critical organ may entail a considerable safety factor—a factor which may, however, be offset by irregularities in the distribution of radioactivity in the tissues of the critical organ itself, especially at the histological level. It is probable that many of the values quoted in this section may have to be revised as more detailed data become available regarding the effects of partial body irradiation and the non-uniform distribution of radioisotopes in tissue. Meanwhile, they form a valuable working guide for persons working with radioactive materials, though some may regret that the data were not presented in a more abbreviated and simplified form.

In the report of the sub-committee on protection against X-rays up to 3 MeV., detailed recommendations are given for the planning, surveying and monitoring of new X-ray installations. Principles to be followed in establishing general working conditions in such installations are outlined and the special requirements of medical diagnostic, medical therapeutic, and non-medical units are discussed separately. The hazards arising from non-useful sources of X-rays (cathode ray oscillographs, television tubes, transmitting valves, etc.) are also discussed. A valuable appendix provides data on the absorption of X-radiation in various shielding materials, and the protective-barrier requirements of different types of installation.

Finally, the sub-committee on protection against X-rays above 3 MeV. and against heavy particles recommends a maximum permissible weekly dose of 0·3 rad/week for X-rays above 3 MeV., and 0·03 rad/week for neutrons in the energy range 0·025 eV.–10 MeV., assuming a relative biological effectiveness of 10 for neutrons in the critical organ—in this case the eyes. Values of neutron flux corresponding to the maximum permissible dosage rate at different energy levels, and relative biological effectiveness figures for different types of particulate radiation are specified.

The report is an impressive example of international co-operation and should receive the serious attention of all who are concerned in the production, handling, and use of radioactive materials and machines producing ionizing radiations. E. H. BELCHER

# OBITUARIES

## Prof. G. F. Shirras

PROF. GEORGE FINDLAY SHIRRAS, who died o June 23, came of an Aberdeen business family, an was educated at Robert Gordon's College in Aberdeen and at the University of Aberdeen, where h distinguished himself outstandingly in economic Choosing an Indian career, he joined the India Educational Service, and at the early age of twenty-four he became professor of economics in Dacc College and was elected a Fellow of the University o Calcutta. For thirty years thereafter he held a succession of posts, doubling some of them. Durin 1910–13 he served in the Finance Department of th Government of India, and during 1914–21 he wa director of statistics, as well as reader in economic in the University of Calcutta. He next spent fiv years as director of the Labour Office of the Bomba Government, and thereafter he was principal an professor of economics in Gujarat College, Universit of Bombay, until he retired in 1939. He then undertook the headship of the Economics Department i University College, Exeter, for the period of the Wa He worked for a time in the Control Commissio for Germany as controller-general of the Financ Division.

Work more to his taste awaited him elsewhere. H held the professorship of economics for a year i Trinity College, Dublin, and in the following yea he worked as visiting professor and lecturer i several American universities, notably at Illinoi Florida and Cornell Universities.

Shirras wrote and published on a large scale an with authoritative effect in the field of statistic Two weighty books sprang from his Indian experienc —"Indian Finance and Banking" and "The Scienc of Public Finance", and also "Some Aspects o Indian Commerce and Industry". Others of h publications were "Federal Finance in Peace an War" and "Planning towards Recovery". He unde took research and wrote on Sir Isaac Newton, bein attracted by Newton's work at the Mint, and h contributed to the "Encyclopædia Britannica". book entitled "The Burden of British Taxation" cam out in 1943.

His enthusiastic spirit conceded nothing t advancing age or to his status of retirement. H may truly be said to have been the victim of h arduous concentration on work and his inten interest in problems and people. He was alert an responsive, whatever the occasion or the company lucid and engaging in speech and gifted in writin He wrote, moreover, a scrupulously clear and gracef hand. Large-headed, of striking features, an virtually bald, he had a rare distinction of appea ance. Outside economics, his chief study was th Bible, especially the Psalms, and the Saints. Born Presbyterian, he became an Anglican, and officiat frequently and acceptably as a lay preacher.

He died prematurely, it may justly be said, a litt before his seventieth birthday. He died, as he wou have wished, in harness, on his way to take pa in the conference of the International Statistic Institute at Rio de Janeiro.

Shirras married Amy Zara, the only daughter the late George McWatters, who survives him. O his two sons, Major Richard Shirras and Maj Douglas Shirras, the latter was killed while servi in France with the Seaforth Highlanders.

## Dr. Stanley Smith

DR. STANLEY SMITH was born at Middlesbrough n March 7, 1883, and educated at Darlington rammar School. On leaving school he worked in e chemical laboratory of the Darlington Forge Co., ut in 1904 he entered Armstrong (now King's) ollege, Newcastle on Tyne, where he graduated in 907, and took his M.Sc. and D.Sc. degrees in 1909 nd 1915, respectively.

Inspired by Prof. G. A. Lebour, Stanley Smith arried out investigations on the coalfields of North- mberland and the Carboniferous Limestone of the lls, his resulting paper (1911) on "The Faunal uccession of the Upper Bernician" being still a andard work. But, of greater importance, this esearch led him to take up the study of the Palæozoic orals, in which he thereafter specialized. Election a fellowship at Armstrong College in 1910 took im to Clare College, Cambridge, where he graduated 1912. His first paper on corals (1913), on onto- enesis and local variations in *Aulophyllum*, set the attern for all his future work, for he insisted, as lways, on the need for basing the revision of genera nd species on the re-examination of the type speci- ens or, if they were unavailable, of topotypes. In is masterly paper on *Lonsdaleia* (1916), Stanley mith wrote, "Inconstancy of detail, but conservation the general plan, is the most characteristic feature the skeletal morphology of Rugose genera", a atement repeatedly validated by later work. A ream of papers followed, either by him alone or in llaboration; these quickly established his world- ide reputation as the leading authority on Palæozoic orals. Of peculiar interest was his description (1930) Valentian corals from Shropshire and Montgomery- ire, for, apart from H. A. Nicholson and R. Ether- lge's classic monograph of the Silurian fossils of the iryan area, no extensive coral fauna of similar age ad been previously described. All his papers were arked by careful observation, honest interpretation, nd polished presentation. They have acted as odels for almost all Palæozoic coral research since, nd, to quote a correspondent, "have really placed alæozoic coral work on its feet".

From 1913 Stanley Smith spent much time during acations at the British Museum (Natural History), om which sprang his long association with Dr. W. D. ang. Their collaboration resulted not only in veral important works revising an extensive range coral genera, but also in their enunciation (1930) of e concept of genomorphs, which has since been plied to other groups of fossils. The Museum blished in 1940 the "Index of Palæozoic Coral enera", of which Stanley Smith was a part-author.

His investigations into the geology of the Bristol ea led to two major stratigraphical contributions, amely, his recognition of Tremadocian Shales in the ortworth inlier of Gloucestershire (1933), and his rrelation of the high Viséan fauna of the Tanhouse eds of Yate with the upper part of the $P_2$ zone 941). With G. A. Kellaway he also described the ly British Jurassic stromatoporoids known (1938), hile earlier (1923) the Geological Survey had pub- hed his important report on the lead and zinc ores Northumberland and Alston Moor. The award him by the Geological Society of London of the yell Medal in 1947 for his palæontological and ratigraphical researches was richly deserved.

Stanley Smith was also knowledgeable in Greek d Roman antiquities. For some years he had been engaged with Mr. D. E. Eichholz, of the University of Bristol, on a new translation of Theophrastus's well-known treatise. His part was to interpret afresh Theophrastus's geological references and records, and to this he brought the same care and enthusiasm that characterized everything he undertook.

Stanley Smith spent his life in the university world. After appointments at Aberystwyth (1913–20), Bedford College for Women (1920–21), and Toronto (1921–22), he became assistant lecturer in geology in the University of Bristol (1922) and retired as reader in palæontology in 1948. He played a full part in local scientific societies, and had been president of the South-Western Naturalists' Union, of which he was honorary secretary for many years.

To work closely with Stanley Smith was to discover a gentle, generous nature, and a lively sense of humour which was always kindly. He was an indefatigable worker, to whom the problem of the moment was all-absorbing. He freely gave of his knowledge, though always in the humble spirit which was one of his great traits. He never lost his innate modesty nor his charming, old-world courtesy, and he would exercise the greatest patience in trying to understand another's point of view. Above all, he was a very loyal colleague and friend.

During the last few years of his life, Stanley Smith suffered from a painful affliction of his back; but despite this he kept at his research work to the end. He died peacefully on July 1, 1955, after a heart attack. His wife, whom he married in 1924, survives him.

H. DIGHTON THOMAS

---

## Dr. J. B. Christopherson, C.B.E.

JOHN BRIAN CHRISTOPHERSON, familiarly known as 'Christo' to his friends, who died on July 21 at the age of eighty-seven, will be remembered for the varied and exciting career which he led as well as for the scientific work that he achieved. He will go down in medical history as the man who introduced the cure of bilharziasis (schistosomiasis) by intravenous injections of tartar emetic.

He had a good family and scientific background, being educated at Clifton College, Caius College, Cambridge, and St. Bartholomew's Hospital, London. He qualified in 1893 and soon afterwards was elected assistant surgeon to the Albert Dock Hospital under Mr. (afterwards Sir) James Cantlie, and he remained in London until 1901. Christopherson was therefore associated with the beginnings of the London School of Tropical Medicine and came under the influence of Sir Patrick Manson. In 1897 he took his final F.R.C.S. and eventually was elected F.R.C.P. in 1913. He was therefore doubly highly qualified. In 1901 he was swept into uniform and went to the South African War, becoming surgeon to the Imperial Yeomanry base hospital. After this experience, he joined in June 1902 the newly created Sudan Medical Service, first as the private doctor to the Sirdar, afterwards becoming director of medical services of the Sudan Government. Five years later he resigned this appointment and became director of the civil hospitals in Khartoum and Omdurman. He had now direct charge of clinical cases and made the most of the rich material under his care.

His career was once more broken by war, when he accompanied Sir James and Lady Berry's Red Cross Unit to Serbia as a surgeon. There he witnessed the break-up of Serbia and was taken prisoner by the

Austro-Hungarian armies. He was, however, soon rescued, and chivalrously released by Slatin Pasha, the Inspector General of the Sudan, who as an Austrian subject had stayed behind in his native country at the outbreak of war.

Early in 1916 Christopherson was in France as the secretary to the War Office Commission on Medical Establishments. Later in that year he was back in Khartoum, where he found several cases of kala-azar who were also infected with bilharziasis—*Schistosoma haematobium*. Having learned of Sir Leonard Rogers's discovery of the specificity of antimony (tartar emetic) in the treatment of kala-azar in Calcutta in 1914, he followed suit, but was surprised to see the schistosome eggs disappear also from the urine, until the cases were cured of both diseases. He also made the pregnant observation, which has since been many times confirmed, that the appearance of the eggs is changed by antimony and that they no longer hatch in water. To Christopherson must therefore go the credit for this notable discovery.

On his return to England after the War, Christopherson was in charge of the bilharzia clinic of the Ministry of Pensions and cured many ex-Service men He then became a specialist in pulmonary disease and physician to the London Chest Hospital, wa also physician for tropical diseases to the Roya Masonic Hospital and took an interest in the tropica diseases section of the Royal Society of Medicine More than twenty years ago he retired to his country home, where he devoted himself to horticulture Christopherson was a sympathetic and friendly person whose great joy was to help others. He had severa endearing and attractive mannerisms; but when occasion warranted he could be tough and firm.

P. Manson-Bahr

---

# NEWS and VIEWS

## Presentation to Prof. F. J. M. Stratton, F.R.S.

On August 23, in the rooms of the Royal Astronomical Society, the president, Sir Harold Jeffreys, presented to Prof. F. J. M. Stratton a copy of "Vistas in Astronomy" at a special conversazione. Those present included foreign astronomers visiting the United Kingdom prior to the ninth General Assembly of the International Astronomical Union. On the same occasion, Prof. H. C. van de Hulst, of Leyden, received the Eddington Medal for 1955. It was originally the occasion of Prof. Stratton's seventieth birthday, after his retirement from the chair of astrophysics at Cambridge, that gave the inspiration for "Vistas in Astronomy", intended as a tribute from his former colleagues, students, friends and admirers everywhere. As publication plans progressed, and when the efforts of the editor, Dr. Arthur Beer, to obtain contributions from leading representatives of all nations met with such encouragement and an increasing number of acceptances, it became clear that this was to be something much more than a *Festschrift*. The final outcome is the present work: a generous and thorough cross-section through the whole of contemporary astronomy and its allied sciences, always emphasizing the lines along which research is particularly active at the moment, its new techniques and methods and their interaction with theoretical developments. These two volumes could be compared to the "Handbuch der Astrophysik", published in Germany before the War, although the present work is much wider in scope. It can rarely, if ever, have happened before that so many leading scholars in a single discipline have co-operated in one book on such a wide international scale; indeed, 215 authors from twenty-six nations have joined to produce 192 contributions. That this was possible is a fitting tribute to the international spirit which has permeated Prof. Stratton's life-work in and for astronomy. Practically every country in the world with an active astronomical life has contributed.

## Physical Chemistry at Sheffield: Prof. George Porter

Dr. George Porter, who has been appointed to the newly established chair of physical chemistry in the University of Sheffield, is distinguished for his pioneering contributions in the field of flash photolysis and kinetic spectroscopy. He was Ackroyd Scholar of the University of Leeds, and after graduating in 1941 entered the Royal Navy, with which h served throughout the War as a specialist in the field of radar; he was demobilized in 1945 with the rank of lieutenant. He resumed his studies in the Laboratory of Physical Chemistry at Cambridge, where in due course he was awarded the degree of Ph.D. fo his work on the development of the method and technique of flash photolysis. The application of this powerful method to the study of primary photochemical reactions, to the measurement of very rapid reactions between atoms and free radicals, and th reactions of explosion and combustion, has resulted in a large amount of new and important work published during the past seven years. Dr. Porter was appointed demonstrator in physical chemistry a Cambridge in 1949 and assistant director of research in 1953. He was elected to a fellowship at Emmanue College in 1952. In 1954 he joined the British Rayo Research Association as assistant director, where he was associated with the launching of the new laboratories recently opened by H.R.H. the Duke o Edinburgh. His many friends in Cambridge and th academic world at large will welcome his return t university life, and wish him every success in th building of his new research department.

## United Kingdom Agricultural and Food Representatives in Canada: Mr. Gilbert S. Lawri

Mr. Gilbert S. Lawrie, senior inspector in the Department of Agriculture for Scotland, has bee appointed agricultural and food adviser to the Hig Commissioner for the United Kingdom in Ottawa, in succession to Mr. W. F. Darke, who has complete his tour of duty in Canada. Mr. Lawrie, who thirty-nine years old, was educated at Georg Watson's Boys College, the University of Edinburg and the East of Scotland College of Agriculture. H academic awards include the Stevens Scholarship in agriculture and the Wardlaw–Ramsay Memori Prize and Medal for the most distinguished studen He was president of the Edinburgh University Agricultural Society and leader of the College of Agriculture livestock judging team. His practical experience includes two years work on arable, stock an dairy farms, eleven years on work closely connected with practical farming, and a short period on th taff of Boghall Experimental Farm. For two years e obtained commercial experience with a well-known rm of Scottish seedsmen. During the War he served the Middle East and Mediterranean countries, and as appointed deputy assistant director of supplies ith executive and advisory responsibilities con- ected with the production, purchase, storage and istribution of agricultural commodities and the dministration of extensive War Department farms Palestine and Syria. In 1946 Mr. Lawrie returned Britain and joined the Department of Agriculture r Scotland, where he has served for the past nine ears.

## se of Radioactive Cæsium for Cancer Treatment

THE United Kingdom Atomic Energy Authority nnounces that a new kind of teletherapy source for reatment of deep-seated cancer is being made avail- ble for use at the Royal Marsden Hospital, London. he principles of such treatment are not new, but his is the first time that radioactive cæsium recovered om 'waste' fission products has been used for this urpose. The source itself is a cæsium salt enclosed a metal cylinder about one inch in diameter and ree inches long. It has an activity of 1,000 curies quivalent to that produced by a thousand grams f radium). The extraction, refinement and pre- aration of the source in its capsule was undertaken r the Industrial Group by the Research and evelopment Branch at the Atomic Energy Factory t Windscale, since the raw materials are stored ere. The process is remotely operated within cells aving concrete walls several feet thick, and the salt finally melted at a red heat into the metal capsule. he initial rate of production of these sources will be e to two a month. With the exception of a single perimental source made in the United States, no her country is making cæsium on this scale. The ggestion for utilizing radioactive cæsium, which s a useful life of some scores of years, from atomic le 'waste' arose about 1952 at Harwell, and the otope Division there suggested that it might be itable for cancer therapy. The general proposal to ake these sources was announced at a Hospital hysicists' Association meeting in London in Novem- r 1954, and the first hospitals to use the sources ill be the Royal Marsden and Royal South Hants. ese hospitals have each designed their own special erapy head to contain the sources; other hospitals ay use a head designed by the Isotope Division at arwell to suit the cæsium sources. Two of these ads were exhibited at the International Conference the Peaceful Uses of Atomic Energy at Geneva.

## ience Museum Collection: Supervoltage Machines for X-Ray Therapy

THE Science Museum, London, has recently thered together in its Atomic Physics Collection a all group of exhibits relating to linear electron- celerators. Although for purely-research purposes e cyclic accelerators such as the betatron and nchrotron are the most widely used for the pro- ction of penetrating X-rays for hospital radio- erapy, the travelling-wave linear electron-acceler- r has great advantages and is being installed in increasing number of hospitals in Great Britain. e Science Museum exhibits comprise sectioned rts of an actual accelerator, presented by Mullard, d.; a most ingenious mechanical model illus- ting the principle of the travelling-wave acceler- r, lent by the Metropolitan-Vickers Electrical Co., Ltd.; several diagrams showing the construction and operation of these accelerators; and a group of photographs showing them in use in the Hammersmith Hospital, London, and in the Megavolt Treatment Unit at Newcastle upon Tyne. Other exhibits in this field recently placed on view in the Museum are a betatron presented by the Clarendon Laboratory, Oxford, a model of the Philips cascade generator at the Cavendish Laboratory, Cambridge, and a mechanical model illustrating its principle lent by the Westinghouse Brake and Signal Co.

## Rockefeller Grant for Genetics Research at University College, London

THE Rockefeller Foundation has made a grant of 30,000 dollars to the Galton Laboratory of University College, London, for furthering research in genetics, this grant being an extension of a similar one which has been given to the Laboratory since 1946. The work at the Galton Laboratory is exclusively concerned with human genetics, particular attention being paid to certain specific aspects. In the identification of the effects of genes in homozygous and heterozygous form by biochemical methods, precise techniques are being developed which enable the presence or absence of a gene to be established with minimal chance of error; these principles are being successfully applied to the urinary excretion of cystine and of β-amino-*iso*-butyric acid. Work on the gradual extension of knowledge concerning the human chromosome map is concerned with pairs of conditions located on the same chromosome, which have recently been discovered by members of the staff; examples are, first, the linkage between elliptocytosis and the *Rh* locus and, secondly, that between the 'nail-patella' syndrome and the *ABO* locus. For the ascertainment of the part played by genes in morphological and metrical traits, both normal and abnormal, noticeable at birth, special attention is being paid to fœtal malformations of specific types, including mongolism; the genetical contribution of the mother to weight of the child at birth is being confirmed. Finally, existing methods, and new ones, are being applied to the statistical and mathematical analysis of human genetical data, special attention being paid to the precise ascertainment of gene frequencies and the exact measurement of linkages.

## Photobiology Group

A PHOTOBIOLOGY Group has been recently established in Great Britain "for the purpose of bringing together biologists, chemists and physicists with an interest in this field, to further scientific discussion in this country and to explore the possibilities of international co-operation". The members of the organizing committee are: *Chairman*, Dr. M. H. Pirenne; *Vice-Chairman*, Prof. J. A. V. Butler; *Secretary*, Dr. Edna M. F. Roe; with Dr. Ph. Bauwens, Dr. E. J. Bowen, Dr. R. Hill, Dr. A. D. Lees and Dr. N. Uri. The first meeting of the Group will be held on October 3, 10 a.m.–6 p.m., at Bedford College, Regents Park, London, N.W.1, when four papers will be read: light absorption and energy transfer (Dr. E. J. Bowen); the present state of photosynthesis research (Dr. R. Hill); photosensitive pigment in the retina (Dr. W. A. H. Rushton); and basic principles in the measurement of light energy (J. S. Preston). Those wishing to attend the meeting should write before September 19 to Dr. Edna M. F. Roe, Chester Beatty Research Institute, Royal Cancer Hospital, Fulham Road, London, S.W.3, from whom further particulars of the Group and its membership can be obtained.

### *The Anthropologist*: New Indian Journal

In the India of to-day many diverse populations are being brought into contact with each other. The network of communications extends to the remotest areas, and tribal cultures at all levels are meeting Western civilization at an increasing rate. This has led to an equally increasing activity in the field of anthropology both by non-Indians and Indians. A welcome is to be extended, therefore, to *The Anthropologist*, a biannual journal edited by the Department of Anthropology of the University of Delhi (Rs. 6 a year or Rs. 3.8 a copy). Although the managing director is Dr. P. C. Biswas of Delhi, the editorial board is not restricted to his Department. Among others, it includes B. S. Guha, director of the Department of Anthropology of the Indian Museum in Calcutta, and the first article in the first number is by Ernst C. Büchi of that Department. Incidentally, this is a most valuable contribution to our knowledge of the blood-group secretor factors in India, a demonstration that the secretor status will become important in recognizing the varied composition of mixed Indian communities. The same number of the journal contains a study of juvenile delinquents by P. C. Biswas, anthropometric studies of the Bhotias by S. C. Tiwari, a cultural essay on the Naiks by J. D. Mehra and papers on fingerprint patterns and blood groups. The second number has now appeared and continues along these varied lines, with contributions by Büchi, notably one on the question of sickling in Indian aboriginals, by G. R. Gayre from Saugar, S. C. Dube from Hyderabad and by the Delhi group. We can look forward to a stimulating contribution from India in this field.

### Risks to Wild Life of Agricultural Chemicals

There has naturally been some concern in Great Britain lest the widespread use of chemicals to destroy pests and weeds should be a source of undesirable or even dangerous secondary effects. The risks run by operatives handling such substances and the possibility of harm from eating food exposed to them have already been discussed in two earlier reports ("Toxic Chemicals in Agriculture", 1951; and "Toxic Chemicals in Agriculture: Residues in Food", 1953). A third report, "Toxic Chemicals in Agriculture: Risks to Wild Life", has now been published (pp. 31. London: H.M.S.O.; 1*s*. 6*d*. net). According to evidence collected from a large number of organizations and individuals and some field-experiments carried out to gain information of a more precise nature, it seems that casualties to mammals and birds (including game) due to sprays are probably small. The substances most likely to be harmful are organophosphorus insecticides applied to brassicas in late summer, arsenical compounds used for potato haulm destruction, dinitro weed-killers applied in spring, and DDT insecticides applied to orchards, carrots and peas. Details of some actual fatalities that have occurred are given, and precautionary methods suggested. Danger to insects is probably much greater but more difficult to evaluate. Effects of sprays on honey bees have received special attention in view of the increasing losses reported, and closer co-operation is urged between beekeepers, farmers and spraying contractors. The inquiry has brought to light the need for research and investigation, and among lines of work suggested are the effect on bird of killing large numbers of insects and the extent t which seed production of sprayed crops is reduced b the death of pollinating insects.

### Rubber Research Institute of Malaya

In the current annual report of the Rubbe Research Institute of Malaya for 1952 (Kuala Lumpur 1954), an account is given of the fourth year o operation of the five-year programme of expansio of the organization and work of the Institute. Th present report contains an introduction by th Director and accounts of the work of the severa Divisions—Soils, Botany, Pathology and Chemistry—each subdivided into research and advisory sections An account is also given of the Smallholders Advisory Service. Work on the rubber tree include breeding and selection, a study of tapping systems various soil investigations, cultivation and manuring and the control of diseases and pests. Work on th product begins from the moment of tapping an continues through all the subsequent processes, tha is, it includes the collection and treatment of late and its processing through to the final product fo export. These studies are in the hands of the Chemica Division. Fuller accounts of the experimental wor of the Institute are to be found in its *Journal*, th annual reports being intended to fulfil a mor general purpose.

### Observatory Department, Mauritius: Report fo 1953

The report of the Observatory Department of th Colony of Mauritius for the year 1953 (pp. 16. Por Louis: Government Printer, 1954) describes th general functions of the Department under variou headings, including provisions of meteorologica services for the government departments, loca authorities, the press and general public, agricultura and commercial interests, the Armed Services, th merchant navy and civil aviation; warnings o tropical cyclones; research; and other activitie Besides the Royal Alfred Observatory, the Department also maintains a number of stations a Pamplemousses, Vacoas, Plaisance Airfield, Agalega St. Brandon and other places. In addition to th director, E. G. Davy, there are an assistant directo and thirty-four others on the staff. Descriptions ar given of the inspections and visits, buildings, meteorological instruments, magnetic instruments and othe equipment, etc. It is interesting to notice tha towards the end of 1953 research work was in progress on the influence of rainfall on the rates o growth and maturity of the sugar cane. As th Colony's income depends almost entirely on agricultural products, the Department devotes mos attention to agricultural meteorology. During 195 progress in reorganizing and extending the Department was more substantial than had been possible t report in previous post-war years. This is chiefl attributed to the provision of adequate accommodation at the Vacoas headquarters, the filling o one of the posts of assistant meteorologist, and th increasing experience of observers appointed in 194 and 1950. Further funds for building having becom available and hopes of filling all staff vacancies i 1954 being entertained, the report ends on th optimistic note that "the prospects at the end o 1953 were brighter than they have been for a numbe of years".

## Abstracts of Papers on Radio Engineering

The amount of literature published in the field of radio and electronics is nowadays so vast that any aid to abstracts and references in the subject is very welcome. As a contribution to this end, the British Institution of Radio Engineers has recently published a booklet entitled "Abstracts of Papers which have appeared in the *Journal of the British Institution of Radio Engineers* over the Past 15 Years" (pp. 48; 1955; from the Institution, 9 Bedford Square, London, W.C.1; 2*s.* post paid). Fourteen volumes of this *Journal* have been published during this period, and the papers abstracted include those presented at the latest convention of the Institution held in 1954. The abstracts, which number nearly four hundred, are arranged according to the Universal Decimal Classification system, and the use of the booklet is facilitated by the table of contents and index to authors.

## The Night Sky in September

Full moon occurs on Sept. 2d. 07h. 59m., U.T., and new moon on Sept. 16d. 06h. 19m. The following conjunctions with the moon take place: Sept. 14d. 0h., Jupiter 5° N.; Sept. 18d. 12h., Mercury 2° N.; Sept. 20d. 16h., Saturn 5° N. In addition to these conjunctions with the moon, Mercury is in conjunction with Spica on Sept. 21d. 02h., Mercury 1° S. Mercury is too close to the sun for observation during September, and the same applies to Venus, which is in superior conjunction on September 1. Mars rises about 4h. 40m. throughout September, and during the early part of the month it is close to ρ Leonis, from which its eastward movement takes it south of σ Leonis about September 24. At the end of the month it is west of β Virginis and soon afterwards moves into the constellation Virgo. Jupiter rises at 3h. 15m., 2h. 35m. and 1h. 55m. on September 1, 15 and 30, respectively, and is conspicuous in the constellation Cancer, in which it moves eastward into Leo. Saturn has an eastward movement in Libra and sets at 21h., 20h. 10m. and 19h. 10m. on September 1, 15 and 30, respectively; its change of position is easily noticed as it moves from east of α Libræ to midway between α and γ Libræ towards the end of the month. There is no occultation of stars as bright as magnitude 6 during the month. Autumnal equinox occurs on Sept. 23d. 20h.

## Announcements

H.M. The Queen will open the new buildings of the School of Veterinary Medicine, University of Cambridge, on October 20.

It is announced that Imperial Chemical Industries fellowships for research in the University of Cambridge have been awarded to Drs. B. H. Briggs and R. I. T. Cromartie (Clare College); P. W. E. Grensted (Christ's College); and O. M. Phillips (Trinity College).

The Research Fund of the Chemical Society provides grants for the assistance of research in all branches of chemistry. About £700 a year is available for this purpose, the income being derived from a donation of the Worshipful Company of Goldsmiths, from the Perkin Memorial Fund, and from other sources. Applications for grants should be submitted by November 15 on the appropriate form, obtainable from the General Secretary of the Society at Burlington House, Piccadilly, London, W.1.

The Massachusetts Institute of Technology is offering a small number of scholarships to British graduates in science and technology (not architecture or town planning) to enable them to attend the summer session of the Institute during June 4–September 25, 1956. Candidates must be less than twenty-eight years of age and have done at least two years work in either industrial or academic research since graduating. Application forms, to be returned by October 14, can be obtained from the Cultural Affairs Officer, American Embassy, Room 302, 41 Grosvenor Square, London, W.1.

The Institute of Metal Finishing has decided to revive in a modified form the William James Memorial Prize, founded in memory of its first honorary treasurer. The competition will be in the form of an essay on any aspect of metal finishing or related subject, and will comprise two sections: essays of a theoretical or technical point of view, for which competitors must not be more than twenty-five years old; and essays based on practical knowledge or experience (no age limit). Two prizes of 10 and 5 guineas, respectively, will be awarded in each section. Essays should be 1,000–5,000 words in length and may be illustrated. They should be sent not later than October 31 to the Honorary Secretary, Institute of Metal Finishing, 32 Great Ormond Street, London, W.C.1.

The Photoelectric Spectrometry Group is carrying out a survey of the demand (in Great Britain) for solvents for spectroscopic purposes, with particular reference to the purity required at specified minimum wave-lengths and the quantities used. A questionnaire has been prepared and is ready for distribution to as wide a field of solvent users as possible. Copies of the questionnaire can be obtained from the assistant honorary secretary of the Group, K. A. Macdonald, 56 Arbury Road, Cambridge.

The Metal Physics Committee of the Institute of Metals is organizing a one-day symposium on "The Mechanism of Phase Transformations in Metals", to be held in the Royal Institution, Albemarle Street, London, W.1, on November 9. The morning session will be devoted to transformations of the nucleation and growth type, and the afternoon session to martensitic transformations. Eighteen papers will be read. Non-members of the Institute may attend the meeting, registration forms being obtainable from the secretary of the Institute, Lieut.-Colonel S. C. Guillan, 4 Grosvenor Gardens, London, S.W.1.

A symposium on "Cavitation in Hydrodynamics" will be held at the National Physical Laboratory during September 14–17. There will be sessions on factors governing the inception of cavitation, experimental techniques, scale-effect factors, effects on hydrodynamic performance and cavitation damage. The opening paper will be a survey by Mr. P. Eisenberg, of the U.S. Office of Naval Research. Further particulars can be obtained from the Director, National Physical Laboratory, Teddington, Middlesex.

Erratum. In "Definition of the Second of Time" on p. 282 of *Nature* of August 13, it is stated, "If the position of the Moon at any time can be determined to 0·05 sec., a period of four years would be necessary to obtain an accuracy of 1 in $10^9$ in time and frequency derived from astronomical observation". 0·05 sec. should read 0·05″.

# CHEMICAL RESEARCH LABORATORY, TEDDINGTON

## REPORT FOR 1954

UNDER the title "Chemistry Research 1954"* are comprised the report of the Chemistry Research Board, signed by the chairman, Prof. E. L. Hirst, and the report of the director of the Chemical Research Laboratory, Teddington, Dr. D. D. Pratt. To these are appended lists of committees of the Board, publications and patents in 1954, staff of the Laboratory on December 31, 1954, metals held by the Pure Metals Committee, standard substances available, and organisms deposited in the National Collection of Industrial Bacteria since publication of the catalogue. Considerable expansion in work on the purification of metals and elements required as semiconductors has been approved by the Board, and, in emphasizing the value of such special services as the provision of standard organic compounds, pure metals and cultures of industrial bacteria, the Board comments on the necessity of providing sufficient staff to prevent reduction of the general research programme. The Board has also recommended commencement of research on the purification of the five elements in addition to gallium and germanium, of interest as semiconductors—antimony, indium, selenium, tellurium and silicon. As part of an investigation on the preparation of the pure rare-earth metals, the separation of the rare earths is being studied using ion-exchange methods. On the recommendation of the Pure Metals Committee, investigations were also in progress on the preparation of pure boron at the Imperial College of Science and Technology, London, and of pure chromium at the National Physical Laboratory, Teddington. The Board's report also notes the provision by the Laboratory of highly purified benzene to a university team acquiring data on compressibility, and pure *p*-xylene to another group working on the thermodynamics of solutions, while joint work with the National Physical Laboratory, now concluded, has made benzoic acid of certified calorific value commercially available.

Other work noted in the Board's report includes the promise of zone melting as a technique for purifying organic compounds, and the pharmacological properties of 4-hydroxy*iso*phthalic acid, available as a by-product in the reaction of carbon dioxide with sodium phenoxide; the value of the chromatographic procedures worked out for the detection and determination of copper, cobalt, niobium and tantalum in geochemical prospecting; the quantitative separation of such metals as copper, cobalt, nickel and iron by elution from a cation-exchange resin by means of an organic solvent mixture; and the use of ion-exchange membranes in an electrolytic cell for separation of ions. Studies on the applications and fundamental characteristics of membranes exhibiting molecular selectivity have been extended to include an examination of the preparation and properties of ion-selective membranes, and encouraging progress has been made towards an understanding of the processes underlying the preparation of polyvinyl alcohol membrane of graded molecular selectivity. A new series o membranes prepared from methoxymethyl nylo promises to find application in industrial dialysis. I is possible that the technique used in the continuou culture apparatus, transferred from Porton to th Laboratory, may be used for increasing the efficienc of some industrial fermentation processes. A laboratory method has been developed for the productio of hydrogen sulphide from sulphated raw sewag sludge; this method could be economically attractiv at a time of sulphur shortage. The use of wast chromate to stop the evolution of hydrogen sulphid from a wet clay pit polluted with refuse at Ne Malden, Surrey, may be of wider application in refus disposal and in the recovery of derelict areas.

The staff of the Chemical Research Laborator numbered 183 at the end of the year, and there wer some twelve guest workers, many of whom came t study special techniques used by the Laboratory The stock of pure metals held by the Laboratory wa increased to twenty-nine by the addition of cerium molybdenum and tungsten, and the addition o naphthalene, 2-methylnaphthalene and *iso*propylbenzene brought the number of reference specimen of organic compounds to forty-four, from which 59 samples were supplied during the year. Depositio of eighty new strains brought the total in the Nationa Collection of Industrial Bacteria to 750, and durin the year 895 cultures were supplied, 522 to researc and educational and 373 to industrial establishment

The director's report again stresses the extent of th advisory work on corrosion problems, on which som 240 requests for advice were received during th year. Many of these were concerned with corrosio by fresh water as in heating systems, in hydrauli systems, and of copper pipes carrying supply waters but the largest number of inquiries was concerne with methods of combating corrosion by sea-wate Problems of corrosion in other environments include that in oil-fired cracking units handling acetic acid an acetone, and in stainless-steel equipment in contac with the oxidation products of acetic and formi acids at high temperatures. Advice was also give on methods of film stripping and the preparation o samples for electron diffraction examination, and th use of capacitance methods for the examination o protective coatings and of radioactive tracers i studying inhibitor mechanism.

Advice was given to a rural district council confronted with a serious financial problem in th cathodic protection of more than a hundred miles o cast-iron water mains, and as a result of a survey i was possible to indicate those sections which require protection, thus saving a considerable part of th cost. Another inquiry was concerned with th external protection of small-diameter mains used fo carrying the various spray fluids for pest control o fruit farms; encouraging results were obtained wit cathodic protection. Many inquiries were concerne with the protection of materials and articles agains corrosion in storage and transit. Advice was give on overcoming corrosion troubles in complete watches intended for export; on the possible effect of vapour-phase inhibitors in stress corrosion and in steam lines in tobacco-manufacturing plant; on the pitting of stainless steel orifice plates stored between gaskets of impregnated-asbestos; the use of *cyclo*hexylamine carbonate as an inhibitor in the upper part of oil storage tanks at Aden and for the protection of boilers, the effect of different finishes on aluminium, on the adhesion of mastics to greenhouse frames, and the accelerated production of a green patina on the Australian War Memorial at Canberra.

---

* Department of Scientific and Industrial Research. Report of the Chemistry Research Board with the Report of the Director of the Chemical Research Laboratory, for the Year 1954. Pp. iv+71. (London: H.M.S.O., 1955.) 3s. net.

Samples of preparations containing 'Gammexane', divinyl ether, casein, γ-picoline, mesitylene pseudocumene, chlorocresols, substituted anisoles and other substances were examined with the infra-red spectrometer for various firms; many requests continued to be received for information and advice on distillation techniques, determination of freezing-point, methods of analysis and physico-chemical constants, and the Laboratory's high-pressure equipment was frequently used in preparative work by industrial firms and academic workers. Much advice was given on the construction and use of the osmometers and thermostat baths developed in the Laboratory for the determination of the molecular weights of polymers and on the application of ion-exchange processes to industrial problems, while many requests for assistance are now being received by the Radiochemical Group.

During the year the Corrosion of Metals Group suspended work on the use of radioactive tracers in the study of the mechanism of corrosion inhibitors and on the electrical study of boiler corrosion, and the study of boiler corrosion was intensified. The corrosion of mild steel in boiling sodium chloride was being examined, and an investigation into the corrosion of mild-steel tubes in Scotch marine boilers was continued. A systematic attempt was being made to correlate the influence of the rate of movement on the corrosion of metals immersed in neutral solutions and natural waters with other factors, especially the temperature and composition of the solution, while a survey was being made of the corrosion-inhibitive properties, with reference to abraded mild steel, of sodium salts of organic acids related to benzoic acid. An electrochemical method has been used to determine the degree of continuity of the protective coating on the inside of water mains. Work on underground and microbiological corrosion was concentrated on examinations of corroded pipes, electrical power cables and soil samples, but further work is required before a practical method of applying tannins to prevent bacterial corrosion of steel can be developed. Other work has been concerned with the effect of silicon on surface films on stainless steels, and new work has been started on wrapping materials for preventing the tarnishing of silver and copper, for which purpose incorporation of chromates of copper, lead, zinc, *cyclo*hexylamine and other amines, copper and lead phosphates, lead nitrite, chromic sulphate and chlorophyll in the paper wrapping has proved particularly effective.

Research in the Inorganic Group has again been mainly concentrated on the examination of flash coaster wastes for selenium and its recovery and on the preparation of elements and derivatives to a high degree of purity. Recovery of selenium by sublimation under oxidizing conditions, with the formation of the dioxide which condenses to a crystalline solid, has the advantage of separation and purification in one step. Extraction of selenium with sodium cyanide has the advantage that it can be applied direct to washed sludges, and the resulting solution when acidified deposits red, amorphous selenium. Many procedures have been examined in the search for satisfactory methods for the microdetermination of carbon, hydrogen and fluorine.

The Radiochemical Group has given special attention to the use of ion-exchange resins for the recovery of metals from solution, particularly the recovery of gold and associated metals from cyanide solution with 'Amberlite *IRA*-400'. Considerable improvements have been made in the chromatographic technique for the separation of niobium and tantalum, and details have been worked out for the determination of rhodium, platinum and palladium, using a paper-strip technique with a solvent mixture of methyl *iso*butyl ketone and hydrochloric acid. A study of the elution of nickel and copper with organic solvents from the cation-exchanger 'Zeocarb 225' showed that an analytical separation could be obtained using acetone containing a controlled amount of water and hydrochloric acid for the elution of copper.

In the Organic Group, purification work on large batches of hydrocarbons, cresols, xylenols and butidenes has been pressed further. In preliminary experiments on the zone-melting of naphthalene containing 0·2 per cent anthracene, the passage of eight zones reduced the anthracene content in half the charge to less than 1/10,000th of its original value. The critical temperature of acetylene has been determined as 35·18° C. by observations of the disappearance of the menisci in sealed tubes immersed in a water-bath. Some nine hundred infra-red spectra were measured during the year, as well as some thermodynamic properties of very dilute aqueous solutions of methylpyridines, ethylpyridines and pyridine at 25° and 40° by a transpiration technique in an attempt to establish why certain of these bases exhibit closed-loop solubility curves. Preliminary results indicate that 4-hydroxy*iso*phthalic acid is less toxic and more effective than aspirin, and at least as effective as aspirin, in counteracting fevers in rabbits caused by a preparation of pyrogen from *Proteus vulgaris*. A study of the reaction of phosgene with ethylene oxide has been extended to epichlorohydrin, propylene oxide, 2 : 3-epoxybutane (*trans*), styrene oxide, *cyclo*hexane oxide and di*iso*butylene oxide. Further derivatives of resorcinol have been investigated in relation to condensation polymerization with formaldehyde, and attempts made to introduce the arsenic acid group into a chloromethylated polystyrene, while the reaction of carbon monoxide with lithium aluminium hydride solutions has been re-investigated using carbon-14 monoxide.

The High Polymers Group concentrated its attention on the same main themes as in 1953, and has made further progress in the investigation of the complexing behaviour of amphoteric resins based on cross-linked polystyrene. A bibliography has been prepared containing approximately four thousand references to the preparation, properties and applications of ion-exchange resins. Factors controlling the semi-permeability of polyvinyl alcohol membranes continued to be studied.

The Microbiological Group continued its fundamental studies on sulphate-reducing bacteria in four main directions: the intermediates formed during the oxidation of simple carbon compounds such as malate; a preliminary study of a polysaccharide formed by these bacteria; the function of their cytochrome in the cell metabolism; and the concentration, purification and identification of various cell pigments. The bacterial cytochrome extracted from large quantities of acetone-dried cells appears to be quite distinct in properties from any cytochrome hitherto described. Studies on the breakdown of phthalic acid by a Gram-negative aerobic rod (NCIB 8334) isolated from an industrial percolating filter indicate that attack does not follow the degradative pathway via *cis-cis*-muconic acid described for several other aromatic compounds. Mutation studies have been started with this organism to obtain strains with a block in the metabolic pathway of phthalate oxidation.

## BIOLOGICAL AND MICROBIOLOGICAL METHODS OF ESTIMATING VITAMIN $B_{12}$

A CONFERENCE on "Biological and Microbiological Methods of Estimating Vitamin $B_{12}$", organized by the Biological Methods Group of the Society for Analytical Chemistry, was held on May 13 in the lecture hall of the Royal Society for Tropical Medicine and Hygiene at Manson House, Portland Place, London. In his opening remarks, the chairman, Dr. L. J. Harris (Dunn Nutritional Laboratory, Cambridge), reviewed briefly the development of the present knowledge of vitamin $B_{12}$, from the discovery by Minot and Murphy in 1926 that pernicious anæmia could be controlled by the use of a liver preparation, to the isolation from liver of the curative principle—vitamin $B_{12}$—by two separate groups of workers, one in Britain and the other in the United States. In the United States the isolation was greatly speeded up by the application of a microbiological control technique, based on the finding that the clinical activity of liver preparations was closely paralleled by their activity for a strain of *Lactobacillus lactis*, which had been shown by Shorb to require an unidentified growth-factor present in liver. Both the *Lb. lactis* factor and the anti-pernicious anæmia principle were later identified with vitamin $B_{12}$.

During recent years, the *Lb. lactis* assay has been largely superseded by improved microbiological techniques, employing a variety of test micro-organisms. In addition, the biological techniques with chicks and rats have been developed and improved. All these different techniques are attended by the inevitable problems of specificity of test, and in some cases of completeness of extraction. Dr. Harris then posed the question: How far do the different methods of assay measure the same thing?

In the unavoidable absence of Mr. F. A. Robinson, his introductory paper was read by Mr. M. E. H. Fitzgerald (Allen and Hanbury, Ltd.). Mr. Fitzgerald pointed out the fundamental difficulties which can complicate the microbiological assay methods. The presence in natural materials of compounds closely related to vitamin $B_{12}$, inactive for higher animals and differently active for different test micro-organisms, can give misleading results. In some of the assays non-specific responses are caused by reducing substances, deoxyribosides or methionine. Then again, in some materials—milk and blood serum, for example—the vitamin is present in a bound form, unavailable to the test micro-organisms. Generally the vitamin can be liberated by heating or enzyme proteolysis in the presence of cyanide. Bu heating with cyanide does not in all instances releas free cyanocobalamin. Mr. Fitzgerald pointed ou that liver contains alkali-stable compounds that ar active for the test micro-organisms, and among thes may be an alkali-stable form of vitamin $B_{12}$.

A survey of published and unpublished value obtained for liver and liver extracts suggests th presence in them of a form of vitamin $B_{12}$ active fo *Lb. leichmannii* but not for *Escherichia coli*. Furthermore, it appears that neither organism responds t some clinically effective forms of vitamin $B_{12}$.

Dr. R. H. Girdwood (Department of Medicine University of Edinburgh) considered the measurement of vitamin $B_{12}$ in the blood serum, and describe in some detail his technique of assay with *Lb. leichmannii*. By this method, normal values rang between 130 and 750 μμgm. vitamin $B_{12}$/ml. Althoug to the clinician vitamin $B_{12}$ deficiency is usually synonymous with megaloblastic anæmia, a low serum vitamin $B_{12}$-level may precede the development o anæmia. Dr. Girdwood suggested that probably the best way to measure serum vitamin $B_{12}$-levels is to use both the *Lb. leichmannii* and *Euglena gracilis* assays.

The next speaker, Dr. D. H. Shrimpton (Rowett Research Institute, Aberdeenshire), discussed the problems of measuring vitamin $B_{12}$ in animal feeding-stuffs, using *Lb. leichmannii* and *Ochromonas malhamensis* as test micro-organisms. In general, enzymic extraction procedures are unnecessary, and may in fact introduce non-specific growth stimulants. Autoclaving the test material with water at pH 4·8 in the presence of a trace of cyanide is usually sufficient to liberate the vitamin quantitatively.

The *Lb. leichmannii* assay is subject to interference by deoxyribosides and by a variety of vitamin $B_{12}$-like compounds. In practice, in the tube assays, interference by deoxyribosides is only rarely encountered, except with materials very low in vitamin $B_{12}$ and rich in nuclear material. Similarly the vitamin $B_{12}$-like compounds are of limited occurrence, being largely confined to natural materials that have been subjected to microbial fermentation.

*Ochromonas malhamensis* closely resembles the higher animals in the specificity of its requirement for vitamin $B_{12}$. But in practice the activity measured by micro-organisms is not necessarily a reliable prediction of the gross vitamin $B_{12}$-activity of feeding-stuffs for higher animals. In fact, the results of a comparison of chick and microbiological assays of a variety of feeding-stuffs indicate that, in general, the less specific micro-organism, *Lb. leichmannii*, approximates more closely to the findings by chick assay. This agreement is possibly fortuitous, but is nevertheless useful at the present stage of development of methods for assessing vitamin $B_{12}$ activity.

Dr. Margaret E. Gregory (National Institute for Research in Dairying, University of Reading) described the measurement of vitamin $B_{12}$ in milk. Three test micro-organisms—*Ochromonas malhamensis*, *Lb. leichmannii* and *Esch. coli*—give closely similar results when used for assaying the vitamin in the milk of several animal species. For routine use, *Lb. leichmannii* is preferred as test organism, largely because no shaking machine is needed with it. A further advantage is that with turbid extracts the growth responses can be measured titrimetrically.

Vitamin $B_{12}$ occurs in milk, mainly as cobalamin, in protein-bound form. In cow's milk the vitamin can be liberated simply by diluting the milk with water and heating at $p$H 4·8 in the presence of a trace of cyanide. In human and pig milk this simple procedure is inadequate, and it is necessary to liberate the vitamin by treatment with cyanide-activated papain.

In the next paper, Dr. Marie E. Coates (National Institute for Research in Dairying, University of Reading) discussed the biological techniques for the assay of vitamin $B_{12}$. It is generally necessary to deplete the reserves of the test animals, either by restricting the vitamin $B_{12}$ intake of the dams or by the inclusion of stress factors in the diet. The chick is probably a more suitable test animal than the rat; but both are likely to over-estimate the potency of crude materials containing unidentified growth factors unrelated to vitamin $B_{12}$. The presence of vitamin $B_{12}$-like compounds does not greatly complicate the biological assays. Only the recently discovered vitamin $B_{12}$III is active, and that only to the extent of one-twentieth of the activity of vitamin $B_{12}$. Although biological assays give a measure of the physiological availability for the test species, there is evidence that some of the naturally occurring bound forms of the vitamin present in one species may be poorly utilized by animals of other species.

The final paper of the conference was read by Dr. W. R. Pitney (Postgraduate Medical School, London), who considered the assay of vitamin $B_{12}$ in blood serum, using *Euglena gracilis* as test organism. The assay is very highly sensitive, and only small volumes of serum are required. It is probable that, with serum, *Euglena* is specific for vitamin $B_{12}$. Earlier reports of non-specific stimulants in occasional samples of serum may well have been due to contamination of glassware with vitamin $B_{12}$. Assays on 560 samples of serum have shown a coefficient of variation of 20 per cent, a degree of accuracy more than sufficient for clinical purposes.

*Euglena* assay shows that vitamin $B_{12}$ in human serum is mostly bound to protein, and this finding is confirmed by dialysis and electrophoresis. Vitamin $B_{12}$ in liver homogenates is assayed as 'free', but behaves on dialysis and electrophoresis as 'bound'. It is probable that vitamin $B_{12}$ occurs in two bound forms in biological materials—a firmly bound form in serum in which the vitamin is unavailable to *Euglena* without preliminary heating, and a looser combination in tissues.

# NON-DESTRUCTIVE TESTING GROUP OF THE INSTITUTE OF PHYSICS

## SUMMER MEETING

THE summer meeting of the Non-Destructive Testing Group of the Institute of Physics was held during June 22–25 in the Royal Technical College, Glasgow. On the evening of the first day, Sir Andrew McCance gave an address in which he traced the progress made, in his lifetime, by the introduction of physical methods into industry, and he emphasized the increase in speed and accuracy which has been achieved by the establishment of non-destructive techniques. He directed attention to the fact that future progress in the testing of materials is dependent upon the systematic investigation of physical phenomena, and he exemplified his argument by reference to the study of damping capacity. Later during the meeting Sir Andrew arranged for members to visit the Lanarkshire Steel Company and the Dalzell Research Laboratory, both of which are at Motherwell.

The first paper of the meeting, by Mr. T. S. Wylie (Department of Natural Philosophy, Royal Technical College, Glasgow), dealt with the course of training in radiography which forms part, albeit a small part, of the four-year course in applied physics at the College. Mr. Wylie showed how great is the care needed in planning the training so as to provide adequate instruction and experience when the time allotted to radiography can be no more than that covered by ten lectures and forty hours of work in the laboratory. He reported on the analysis, which he has carried out, of the requirements for a course in radiography, and explained, by reference to a number of charts and tables, how he has established a course in which the progress of the lectures is closely integrated with the progress of the experimental work and from which all unnecessary detail has been eliminated. During his lecture, and again in the discussion which followed, Mr. Wylie stated that he had found lack of knowledge of foundry practice on the part of students one of the biggest handicaps in the study of radiography; he stressed the need for students to spend time working in a foundry.

The importance of radiography to the shipbuilder has long been recognized, and Mr. Duffy (Clyde Shipbuilders' Association) explained how, at the time of the change from the use of riveted joints to welded joints, the Clyde shipbuilders combined together to operate an organized district scheme for the radiographic inspection of welded structures. He described the way in which this scheme operates and gave details of the equipment which is made available by it for inspection purposes. Owing to the difficulty of moving around ships with large X-ray units, the use of isotope sources for site work is preferred; and in this connexion Mr. Duffy remarked that, because of the portability of isotopes, their use shows considerable economy over that of X-ray units, even though longer exposure times are required.

Mr. Duffy dealt with the precautions necessary to protect personnel from radiation and high-tension equipment on site inspection. He then directed attention to the impossibility of carrying out a one hundred per cent inspection of the welds on a ship, and stated that the main object of radiographic examination in shipbuilding is that of testing the welder rather than the weld. Radiography is best used as a test for control of weld quality, and nobody should be allowed to make a single weld on a ship before his ability has been assessed by radiographing test plates welded by him. Mr. Duffy concluded his paper by describing the types of defects found in welds and by showing how radiographic examination enables wrong welding procedures to be detected.

Although the capital expenditure involved in the purchase of industrial boilers is large, this expenditure is small compared with the cost of the fuel consumed by the boilers. Boilermakers are, therefore, always trying to increase the thermal efficiency of their products, and this is done by designing boilers to operate at higher temperatures and pressures. The paper by Mr. W. E. Marskell (Babcock and Wilcox, Ltd.) was therefore concerned with the establishment of a system of non-destructive testing which would ensure the safe working of boilers. He emphasized the importance of radiography and gave examples of the use of X-rays and $\gamma$-rays. Much attention was given in the paper to the increasing use of ultrasonic testing, its appeal being attributed to its sensitivity to the detection of small defects, its cheapness and to the fact that by its use no precautions need to be taken for the protection of personnel. Mention was made of magnetic testing, particularly in connexion with the detection of sub-surface faults in butt-welded pipes.

The lecture by Dr. R. W. B. Stephens (Imperial College of Science and Technology, London) was concerned with the physical principles underlying the establishment of non-destructive testing techniques. He confined his attention to surface properties and reviewed those properties which are, or could be, used as a means of detecting 'geometrical defects' (surface cracks and lack of flatness) and of studying the surface structure of materials. The difficulty of defining exactly what is meant by a surface was mentioned, and attention was directed to the care which must be exercised to ensure that the process of surface examination does not in itself involve a change in the conditions of the surface (for example, cutting sets up mechanical strains; polishing may destroy crystallinity). Dr. Stephens's treatment of his subject included a review of the optical properties of surfaces with reference to their application as a basis for the development of non-destructive testing methods; and an appraisal of the effectiveness, for the examination of surfaces, of magnetic and electrostatic fields, eddy currents, mechanical waves (Rayleigh waves), surface (electrical) resistance, heat flow, electron emission and spectroscopic examination.

Dr. D. Tabor (Department of Physical Chemistry, Cambridge) began his lecture on the physical meaning of indentation and scratch hardness by describing the nature and area of contact between two surfaces. He then went on to define 'hardness' as the resistance of a material to deformation and to describe the methods of measuring hardness. He showed that values of indentation hardness provide a measure of the plastic properties of materials and not of their elastic properties. By means of an elementary examination of stress–strain curves, he defined the term work-hardening index, and, with reference to the Vickers and the Brinell hardness, he derived the simple relationships between hardness and yield strength for materials which do, and do not, work-harden. Dr. Tabor then turned his attention to the subject of scratch hardness. He referred to the first scratch-hardness scale formulated in 1824 by the geologist Mohs, and he discussed the establishment of scratch-hardness scales as well as the conditions under which one surface will scratch another. He explained the fact that under high hydrostatic pressure brittle materials become ductile, and showed that the scratch hardness and the frictional behaviour of brittle materials are dependent upon their plastic properties and not upon their brittle properties.

Mr. H. L. Carson (British Welding Research Association) gave an assessment of ultrasonic techniques, with special reference to welds, in which he traced the development of weld inspection by ultrasonics. He made a critical survey of the methods of injecting ultrasonic beams into welded materials and paid particular attention to probe design, the coupling between the probe and material under inspection, the monitoring of the contact between the probe and the material by use of subsidiary crystals, and the choice of direction of the ultrasonic beam relative to the position and orientation of the weld. The value of the use of shear waves for weld inspection was emphasized and, with reference to particular cases Mr. Carson showed when single probes and double probes should be used.

The problem of assessing the significance of defects was stated as presenting the greatest difficulty associated with ultrasonic inspection of welds. It is frequently not possible to decide whether the cathode-ray tube trace, showing the presence of a defect, is indicative of a serious defect or not. In this connexion, Mr. Carson pointed out the necessity for some form of instrument standardization and criticized the present standard test-block procedure which has been established for this purpose.

In their paper on problems in the interpretation of ultrasonic tests on steel, Mr. I. M. MacKenzie and Mr. R. Kennedy (Colvilles, Ltd., Motherwell) directed attention to the shortcomings of such tests as a means of inspecting steel. While they recognized the valuable contribution made to inspection by ultrasonic methods, they were able to point to many examples where ultrasonic tests have yielded erroneous indications and, although these examples were of an exceptional nature, it was easy to appreciate that the exceptions tend to undermine the confidence which the steel-maker must have in his testing procedure. Mr. MacKenzie and Mr. Kennedy left no doubt in the minds of the physicists in the audience that improvements in ultrasonic testing are essential and that these improvements can only be achieved by intensive effort on the part of physicists working in close collaboration with metallurgists and engineers.

Preliminary experimental work to determine the uses to which neutron radiography can be put is being carried out at the Atomic Energy Research Establishment, Harwell, and Dr. J. Thewlis and Mr. R. T. P. Derbyshire described the progress which has been made so far at the Establishment. An introductory account was given of the properties of thermal neutrons, from which it was seen that there are striking differences in the absorption, by materials, of X-rays and neutrons (for example, water has a high absorption coefficient for neutrons, whereas lead is relatively transparent to them), and, although the highly penetrating character of neutrons should make them suitable for radiography, their negligible photographic effect is a handicap to their use. The experimental work described was concerned mainly with the construction and performance of intermediate screens which have been devised for overcoming this difficulty, and a series of radiographs obtained with the apparatus described was shown with the object of illustrating the kind of application to which neutron radiography can be put. The most effective source of neutrons is a nuclear reactor; but Dr. Thewlis described a number of other sources which could be installed and used in industry if neutron radiography is ever required.

The final paper, by Dr. E. G. Stanford (Aluminium Laboratories, Ltd., Banbury), dealt with the scope of non-destructive testing. Tests are made on materials to check their dimensions, to detect the presence of defects and to determine their properties, and in his paper Dr. Stanford enumerated the tests devised for these purposes. Testing procedure involves the examination of specimens taken from a material or the examination, by non-destructive methods, of the material itself. Tests made on specimens may involve the destruction of the specimen, a change in the material of the specimen without its shape being destroyed, or no change whatever in the specimen. The field of non-destructive testing should cover all tests except those in which the specimen is destroyed.

Engineers are usually obliged to attach most importance to those properties which are determined from tests in which the specimen is destroyed. This means that the actual material which goes into service is not tested. As advances take place in engineering design, and materials are required to operate under increasingly severe conditions, it is becoming essential to know that the material put into service has the properties quoted from tests on specimens taken from it. Non-destructive tests should therefore be developed which will give this information, and the means of establishing such tests will come by three lines of study: how those properties determined by non-destructive tests vary with the constitution and structure of materials; how these properties can be used to identify changes in constitution and structure; and how to relate changes in constitution and structure to those properties which are determined by destructive tests.

# APPLICATIONS OF ULTRASONICS

## CONFERENCE IN MARSEILLES

THERE have been a number of conferences on various aspects of ultrasonics during the past few years, and that held in Marseilles during May 23–28, under the auspices of the Centre National de Recherches Scientifiques, was devoted to applied ultrasonics, though some papers on fundamental aspects were also read. The conference was subdivided into four sections comprising physical, chemical and medicobiological applications and transducers. Most papers fell into the first and third divisions. Prof. F. Canac (66 rue St. Sebastian, Marseille), the organizer of the conference, expects to publish in a book all the papers presented, and they may also appear as a special volume of *Acustica*.

The scientific part of the meeting opened with an account of the pioneer work of Langevin and Florisson in the use of ultrasonics for underwater detection, recalled by Prof. F. Canac, and then Prof. A. Giacomini presented statistics of the different types of applications during the past twenty years. About fifty sectional lectures and papers were read, of which it is only possible here to mention those which involve recent applications in industry and the like.

R. G. Busnel and M. Degrois showed an interesting film of the actions produced in a liquid under pressure when small cavitation bubbles appear in the liquid and the familiar geyser rises from the free surface. At higher pressures the latter disappears, particularly when the pressure is diminishing, and the cavitation nuclei coalesce leaving a flat free surface. No explanation was offered for these experiments, and as only one frequency was tried it is not possible to determine whether resonant vibrations of the cavity bubbles are concerned.

Prof. E. Meyer showed some interesting experiments with ultrasonics in a large box, imitating on a small scale the distribution of the sound amplitude throughout an auditorium due to a steady audible source. It was possible, by varying the form of protuberances applied to a wall and by having the other walls either hard or absorbent, to study the diffusive properties of the box for the ultrasonics. Dr. E. G. Richardson gave an account of the incidence of ultrasonics in recent aeronautical research, dealing in particular with the high-frequency output of jet engines and relaxations in substitute vapours used in supersonic wind-tunnels. The former was also the theme of an investigation by Mlle. M. Merle, who used small jets in the laboratory.

L. Bergmann described an apparatus for quickly giving warning of the presence of an explosive mixture in a room, by the use of an ultrasonic interferometer, while C. Florisson and R. Esche and collaborators described apparatus for coagulating and generating, respectively, aerosols of fine dispersion; these are of importance in chemical industry and the practice of medicine. In the same field V. Gavreau described the development of ultrasonic whistles which can be applied to—among other things—the coagulation of smoke.

A considerable number of papers occupied the medical and biological section, mainly emanating from Germany, where this type of application is much developed. Applications of ultrasonics in this field ranged from the treatment of nervous diseases and cancer to promoting the germination of wheat and killing of bacteria. To some of these a specific effect of frequency (or of wave-length) was attributed; but in many applications, apart from the concentration of energy to be obtained, it seems that vibrations over quite a gamut of frequency can be effectively employed (this is also true of the formation of emulsions, as M. Degrois and his colleagues showed).

After thirty years of experience of ultrasonics in applied biology, it is not yet definite how far the effects are thermal and how far mechanical, but Dr. J. Stetler gave an interesting lecture on this problem, describing some careful experiments in which he sought to distinguish these two effects by using first continuous waves and then reiterated pulses of different lengths. In the fourth section, it is only possible to cite a lecture by C. F. Brockelsby, in which he gave many data for the development of magneto-striction generators of high power.

# INSTITUTE FOR SCIENTIFIC RESEARCH IN CENTRAL AFRICA

## REPORT FOR 1952

THE fifth annual report of the Institute for Scientific Research in Central Africa, Leopoldville, Belgian Congo, covering the year 1952 has recently been published*. Besides the administrative reports, among which that of the director, L. van den Berghe, gives a summary of the scientific work of the Institute during the year, it includes V. G. Dethier's paper on the biting response of tsetse flies, a bibliography of *Plasmodium berghei* by I. H. Vincke and M. Lips, an account by the director of the laboratories of the Institute at the Scientific Research Centre at Kivu, Lwiro, and a long account of the medical mycology of the Belgian Congo by R. Vanbreuseghem. A bibliography of papers published during the year by members of the Institute's staff or associated investigators is amplified by abstracts of the papers.

* Institut pour la Recherche Scientifique en Afrique Centrale (I.R.S.A.C.): Cinquième Rapport Annuel. Pp. 377. (From the Institute's Offices in Brussels, 1955.)

Among investigations in progress noted by the director in his report are an entomological inventory of the different natural regions as a prelude to a study of their fauna and a study of the entomological fauna of the remains of the primary forests still existing in Ruanda-Urundi; investigations on the cycle of trypanosomes; and studies of climatic and technical problems in tropical habitation. Other studies have related to the control of malaria among children in the plain of Ruzizi and the territory of Uvira, the transmission of trypanosomiasis by *Glossina brevipalpis* on the River Malagarasi, the use of electrophoretic diagrams in nutrition studies, such as in a case of kwashiorkor, morphometric studies of the lakes of Bulera, Luhondo, Mohasi, Mugesera, Bilala, Sake and Bugwero, in Ruandi, including also plankton studies and the study of the littoral fauna. Therapeutic studies of kwashiorkor, studies of the incidence of goitre in Ruanda, of the sensory physiology of the tsetse, a physico-chemical and hydrobiological study of Lake Gileppe, near Verviers, and of the variation with altitude of the potential gradient of the sun have also been made, and biochemical methods applied to the determination of proteins, protein fractions, lipids and cholesterol of blood.

Intraspecific variations among *Hyperolius viridiflavus* and *H. lateralis* have been studied in Ruanda and Urundi; *Schoutedenella mossoensis* sp. n. du Mosso, probably a new race of *Hyperolius cinnamomeoventri*, a Congo species encountered for the first time in Ruanda in the valley of the Akanyaru, was captured as well as three other species not previously captured in Ruanda-Urundi: *Atractaspis bibroni rostrata*, *Hyperolius oxyrhynchus* and *Schoutedenella lameerei*. An inventory and ecological study were made of some arthropods of the Great Lakes, and a study of the indigenous political organization of the kingdom of Ruanda was completed for presentation as a thesis. An inquiry into the migrations and biology of the fish of a river torrent in the Tanganyika basin, studies of the syncline of Itombwe between Lakes Kivu and Tanganyika and of the frequency of the sickle-cell trait, examination of anthropometric practices in Ruanda-Urundi, the prehistoric industry of the plain of the Lemba, anæmia in states of malnutrition and paludism in mammals and the invertebrate hosts are also noted, as well as the reorganization of the system of demographic inquiry in Ruanda-Urundi.

# HOP PICKING BY MACHINE

SINCE the Second World War, shortage of labour for picking hops by hand has forced English growers in increasing numbers to turn to the use of picking machines. In 1947 it was estimated that not more than eight machines were in use; the figure had increased to more than a hundred machines in 1954 and a further hundred machines are on order for 1955. These machines are mainly large stationary types which are best suited to the needs of growers of larger acreages. Smaller machines are being produced for the smaller growers, so it is probable that within a few years English hops will be picked mainly by machine.

These developments have been kept under observation by the Department of Hop Research of Wye College, Kent. Each year from 1949 until 1953 inclusive, the Department, with encouragement and financial help from the Agricultural Research Council, has organized surveys of picking machines at work on the farms of commercial growers. The results of these surveys have been published in detail in the annual reports of the Department for the years 1950–53 inclusive. At the request of the Hops Marketing Board, the findings of the surveys have been summarized in an article by G. P. Chater and Miss C. L. Jary*.

The main point emerging from the surveys is the importance of intelligent and efficient management; the best of picking machines will give poor results if badly managed.

The concept of machine picking as a factory process is a valid one. From plant to pocket the hops pass along a production line, and, as in all mechanized industries, good management based on a clear understanding of the process as a whole is essential if a good final sample of dried hops is to be produced.

The chief disadvantage of all picking machines is the amount of breakage they cause to the hop cones. Such breakage makes for difficulties in subsequent cleaning and drying and may lead to wastage of hop material in general and of resins in particular. The subject of resin-loss is a controversial one. An investigation is nearing completion at Wye in which a series of forty-two pairs of pocket samples from the 1954 crop is being examined. Each pair consists of hops of the same variety and from the same farm, one sample of each pair being hand picked and the other machine picked. Preliminary results show that in thirty-five of the forty-two pairs of samples the hand-picked hops appear to have more resin than the machine-picked ones; in the remaining seven pairs the machine-picked hops appear to have a higher resin content than the hand-picked samples.

One of the most important objects of future research on machine picking must be to reduce damage to the cones. In addition to preventing wastage and improving drying performance, such reduction in the breakage of cones would reduce the risk of resin-loss. Future research in England may also have to pay attention to the cleaning of machine picked hops. In the United States, picking machines have been in general use for some ten years and more than 90 per cent of the crop there is now picked by machine. American growers are now producing by machine-picking large quantities of dried hops with less than 2 per-cent by weight of leaf and stem. Data collected in the Wye College surveys suggest that English machine-picked hops have from 3 per cent to 12 per cent of leaf and stem and that hand-picked hops have 3–6 per cent; such information is too scanty to permit of large generalizations. It is possible, moreover, that the relative cleanness of American machine-picked hops is achieved by tolerating a degree of wastage of broken hops that could not be accepted at present in England. This aspect of machine picking would appear to merit investigation.

In the Wye College surveys the approach was that of the hop grower rather than that of the agricultural engineer. This approach was the only one permitted by the circumstances and has yielded valuable results. It has, however, obvious limitations, and the time has come for research on picking machines, and on the related problem of the drying of machine picked hops, to be taken up by a team of agricultural engineers.

If research on the machine becomes the responsibility of the agricultural engineer, the growing o ops for the machine remains the responsibility of he hop grower.

---

* Obtainable from the Secretary, Wye College, Ashford, Kent. 1.

The correct interpretation of the results of all this vork demands more knowledge of how the hop plant grows than is at present available. It is hoped that t may soon be found possible to appoint a plant hysiologist at Wye College to make a detailed study f the pattern of growth of the hop plant.

## THE HANDICAPPED CHILD

IN a school population of approximately 5,970,000 in England and Wales, 16,719 were pupils known o school medical officers to be physically handiapped. The most frequently recorded conditions esponsible for the handicap included heart disease 4,453), cerebral palsy (2,954), deformities and mputations of the limbs (2,053), poliomyelitis (2,001), uberculosis (1,766) and spina bifida (543). It is stimated that only about one child in every thousand s too severely handicapped to become entirely selfupporting and to be able to live a full life. The ncreasing emphasis of recent years upon the advisbility of keeping such children at home has added onsiderably to the responsibility involved in the are of these children. It is not only in the case of he deaf child that there is often more than one atient. Indeed, there are often three, for both arents as well as the child have to be considered. o handicapped child can achieve the optimum enjoyment of life unless the parents are prepared to carry ut to the full the instructions of their medical advisers.

The family doctor's responsibility in dealing with hese unfortunate children is threefold. In the first lace he must be on the look-out for any handicap o that he can detect it at the earliest possible age nd refer the child to a specialist for advice as to hat can be done to overcome, or at least ameliorate, he disability. Secondly, he must know of the rganizations, voluntary and statutory, which are vailable to help such children. Thirdly, there is the upervision and care of the child in the home.

All these aspects are dealt with in a remarkably ood issue of *The Practitioner* (174, No. 1042; April 955), which includes articles by specialists on hildren's disabilities.

## BREEDING BEHAVIOUR OF THE AMERICAN COOT

SOME peculiarities in the breeding behaviour of the American coot (*Fulica americana*) have been escribed by G. W. Gullion (*Auk*, 71; October 1954). The bird is probably always monogamous in its exual behaviour. If one mate disappears during the esting season, a second mate may be accepted ithin forty-eight hours. Among the resident coots ith secure territories, pairing seems to be as permanent as the life of the birds or their ability to aintain a territory.

Coots breed in a habitat which contains abundant esting material, and they use this material freely constructing floating structures associated with reeding. These structures are bulky, and since aterials seldom present a procurement problem, ey are not built for permanence but must be lded to repeatedly while in use. Eggs are seldom id in more than two of the eight or nine structures which are usually built. The other structures are utilized for resting, roosting and brooding sites.

Three types of structures built by coots—a display platform, the egg nest and a brood nest—follow one another in a definite sequence, and breeding events can be reliably predicted by their appearance. Certain modes of construction permit the identification of a nest type even before it is placed in use.

Copulation normally, perhaps always, takes place on a display platform. There is little or no precopulatory display or chase, and the two birds resume normal activity within two or three minutes following copulation. Eggs may appear before the nest is completed and are laid daily in the very early hours of the morning. The nest is completed and lined by the time the clutch is complete.

Incubation is continuous and is shared by both sexes, the male probably doing the greater share of it.

When deposition of the clutch is just beginning the female incubates all night, but otherwise the male incubates from dusk to dawn; the female always takes about a four-hour shift at dawn and then shifts of about one-hour duration follow until sunset. Young coots are quite helpless until a day or so old and require prolonged parental care. The male parent does most of the brooding during the staggered hatching period, while the female brings food to the nestlings and takes the older ones away to feed and brood. Later, the parents divide the brood during feeding and brooding.

## CHLOROPLAST STRUCTURE

IN a study of the structure and swelling properties of the chloroplasts of *Nitella cristata*, F. V. Mercer, A. J. Hodge, A. B. Hope and J. D. McLean have made some new and interesting observations and stated some tentative conclusions (*Austral. J. Biol. Sci.*, 8, 1, 1; 1955). Electron-microscope studies of ultra-thin sections have shown that the normal chloroplast consists of about 40–100 lamellæ *c.* 70 A. apart, enclosed by an external membrane *c.* 70 A. thickness. Grana do not occur. The space within the chloroplast not occupied by the lamellæ is filled with a granular material resembling the cytoplasm. The chloroplast often contains a considerable number of osmiophilic globules *c.* 0·1μ in diameter lying between the lamellæ, their staining reaction with osmic acid indicating that they are probably lipoidal.

Numerous small osmiophilic bodies *c.* 100 A. or less in diameter are associated with the lamellæ. Starch grains, when present, occur between the lamellæ and appear to be enclosed within by a membrane. During swelling in hypotonic solutions, chloroplasts change in shape from disk to sphere to cylinder. Swelling results from the formation of vacuoles between the external membrane and the rest of the chloroplast (blebs), by increase in interlamellar spacing and by the formation of vacuoles between the lamellæ. The interlamellar vacuoles form by the lamellæ rounding up and coalescing to enclose the granular interlamellar material. Quantitative results for the volume : osmotic pressure relations, the volume : *p*H relations, the surface charge, and the apparent free space for potassium chloride show that swelling is an osmotic process. The osmotic gradients arise from (*a*) a Donnan system associated with the interlamellar material, and (*b*) from diffusible solutes present in the interlamellar solution. The high values for the apparent free space and the volume : *p*H relations indicate that the chloroplast membrane is differentially permeable, not semi-permeable. The degree of swelling of chloroplasts in solutions is controlled by the osmotic pressure and pH of the solution, the differential permeability of the chloroplast membrane and lamellæ, and the cohesive forces maintaining the structure of the membrane an lamellæ. By analogy, it is suggested that tl mechanism controlling the water relations of mit chondria, which also possess lamellar structur bounded by a thin membrane, may be similar t that of the chloroplasts.

# POTASSIUM–ARGON AGES OF SOME LEWISIAN AND FENNOSCANDIAN PEGMATITES

By Prof. ARTHUR HOLMES, F.R.S.
Grant Institute of Geology, University of Edinburgh
Dr. H. A. SHILLIBEER and Prof. J. T. WILSON
Department of Physics, University of Toronto

THE apparent ages, determined by the potassium–argon method, of ten samples collected from pegmatites, varying in composition from potash-rich granite to practically pure potash-feldspar, are presented in Table 1. Omitting three 'ages' which fall below 1,000 million years, for reasons stated below, the average age of the Lewisian pegmatites investigated is 1,090 ± 70 million years. Microcline from the Arendal district of southern Norway has nearly the same age, whereas a Svecofennian pegmatite in Finland is found to be about 1,800 million years old.

The age of each specimen, $t$, was calculated from the equation

$$t = \frac{1}{(1+R)\lambda_\beta} \cdot \ln\left(1 + \frac{1+R}{R} \cdot \frac{{}^{40}\text{A}}{{}^{40}\text{K}}\right) \text{ years,}$$

which, on substituting the data here adopted, becomes

$$t = 4{\cdot}202 \log_{10} (1 + 12{\cdot}24\ {}^{40}\text{A}/{}^{40}\text{K}) \times 10^9 \text{ years.}$$

$R$ is the branching ratio, defined as the ratio of the rate of orbital electron capture to the rate of β-emission. For $R$ two values have recently been published, 0·089 ± 0·003 [1] and 0·085 ± 0·005 [2]. The first value is adopted here because it has been further substantiated by recent work at the University of Toronto upon nine samples of potassium minerals from pegmatites already dated by accompanying uranium minerals and ranging in age from 330 to 2,600 m.y.

For $\lambda_\beta$, the transformation constant for β-emission, a value of $0{\cdot}503 \times 10^{-9}$ y.$^{-1}$ has been obtained from eleven of the most recent counting experiments[2].

$^{40}$A is the mass of radiogenic argon-40 present per gram of sample as determined by a procedure which has already been described[3]. At least two determinations were made on all samples except 1159-*A*. All argon samples were analysed by a mass spectrometer. In no case did the abundance of argon-36 indicate the presence of more than 8 per cent atmospheric argon. Corrections were made for this; but even the largest correction lowered the resulting age by only 2 per cent. The uncertainty shown is the standard deviation of individual measurements.

$^{40}$K is the mass of potassium-40 per gram of sample. It was calculated from potash analyses by adopting Nier's value for the isotopic abundances of potassium[4]. Reuterswärd[5] has obtained a value for the abundance of potassium-40 that agrees to within 1 per cent with Nier's result. At least two analyses were made for all the Scottish samples. The analysts were W. H. Herdsman (Glasgow), who used a gravimetric method; and the Chemical Research Laboratory, Teddington, W. R. Inman (Canadian Bureau of Mines, Ottawa) and K. Watson (University of Toronto), who used flame photometers. The age were calculated from the mean values. The No wegian sample was analysed by W. R. Inman an W. H. Herdsman, and the Finnish samples by H. I Wiik (Geological Survey of Finland).

The experimental results are listed in Table I The limits of uncertainty given for the ages are base upon an estimated mean probable error of 10 pe cent in the value of $^{40}$A/$^{40}$K, which in all cases i greater than the combined error due to the argo and potassium determinations.

1243-*A*. White perthitic microcline, with sporadi inclusions of quartz, collected by Mr. Martin Kürste from a 16-ft. wide pegmatite trending east-north east across the anorthosite of the eastern slopes o Roneval, South Harris. The rocks of this region hav been described by Jehu and Craig[6], the petrolog and geological history by Davidson[7], and the pegmatites, as sources of alkali feldspar, by Robertson[8]

1244-*A*. Pink perthitic microcline with irregula streaks of quartz and muscovite, collected by Dr R. M. Craig[9] from the north-east-trending Northto pegmatite near Chaipaval, South Harris. For detaile description and maps see Robertson[8].

1159-*A*. Pink perthitic microcline, with inclusion of quartz and streaks of sericite, collected by Dr R. M. Craig[9] from a north-east-trending pegmatit on the islet of Shillay in the Sound of Harris, abou six miles west of the south-west coast of Sout Harris. The locality is shown at the extreme top o Plate IV of Jehu and Craig's paper[6].

1173-*A* and 1242-*A*. These were specimens from collection made by Dr. R. Campbell[10] from a pegmatite north of Rhiconich, extending west-north west from Cnoc an Tuir towards the north-east shor of Loch Inchard. The locality is in west Sutherland about 13 miles south of Cape Wrath, and is show on Fig. 6 of Robertson's report[8], on p. 12 of whic the pegmatite is fully described. Although th original specimens looked much alike and consiste of pink microcline, buff albite-oligoclase, quartz an micas, microscopic examination revealed that whereas the second was almost ideally fresh, the fir was richer in quartz and had been intensely altere by sericitization, chloritization and introduction o ferruginous matter along cracks, cleavages and inter granular boundaries. Since such alteration woul inevitably promote leakage of argon, the relativel low age yielded by 1173-*A* is not surprising.

1160-*A*. Pink perthitic microcline with inclusion of quartz, collected by Prof. D. B. McIntyre from 100-ft. wide pegmatite at Badcall Quay, about a mil north-west of Laxford Bridge at the head of Loc

axford. The locality is *G*, Fig. 6, of Robertson's eport[8].

1250-*A*. Perthitic orthoclase, somewhat sheared nd showing undulose extinction, collected by Dr. . Sutton and Dr. Janet Watson from a north-west-ending pegmatite at Geodh' Eanruig, about a mile est-south-west of Scourie Hotel and 5½ miles south-est of Badcall Quay. The relatively low argon ontent of this specimen may possibly be due to the eating effect of a thin basic dyke of unknown age hich cuts the pegmatite.

1251-*A*. Perthitic microcline collected by Dr. J. utton and Dr. Janet Watson from a north-west-ending pegmatite about 500 yards west of Cnoc an hir Bhreige (west of Badcall village and two miles uth of Scourie). This and the two foregoing pegatites are mapped on Plate XX of Sutton and atson's paper[11]. The low age found for 1251-*A* ay perhaps be accounted for in the same way as at of 1250-*A*, as Dr. Sutton informs us that a lerite dyke of unknown age is seen very close to e pegmatite and appears to cut across it.

Excluding the three samples from which loss of gon is suspected, the average age found is about 090 ± 70 m.y. So far, the only European age terminations of this order are those dating the gmatites of the Arendal district of Norway, tending north-east–south-west from Langesundord to Kristiansand, where the geological sequence s a general resemblance to that of Harris, as dicated in Table 2. The Cape Wrath to Scourie quence is also similar, save for the intervention of suite of north-west dykes which has enabled Sutton d Watson[11] to establish the existence of two sets structures and metamorphisms in the Lewisian oks, distinguished as 'Scourian' and 'Laxfordian'. For this reason it cannot yet be regarded as certain that Scourian rocks are represented in the Harris and Arendal successions, as Table 2 suggests. The dated pegmatites, however, all appear to be late Laxfordian.

1174-*A* is a massive pink microcline (Currie Collection, Grant Institute) from a pegmatite of the Arendal suite, south of Langesundfjord. The age obtained, 1,020 ± 70 m.y., agrees within the limits of error both with the Lewisian ages here recorded and with the isotopic age (lead method) of 1,090 m.y. given by Nier[13] for one of the many cleveites from the Arendal district analysed by Mme. E. Gleditsch. This very important check suggests that the Laxfordian and Arendal orogenies were at least approximately contemporaneous. The Grenville pegmatites in Canada are also of about the same age, and here, too, they have been consistently dated by both uranium and potassium minerals[5,13].

Until recently, the Arendal district was regarded as part of the Svecofennian orogenic belt (Bugge[14]), and the age, 1,090 m.y., was thought to be representative for the late pegmatites of that belt, particularly as some of the uncorrected chemical ages of radioactive minerals from southern Finland had been found to be of the same order (Lokka[15]). It was therefore a surprise when the argon method applied to some potash feldspars collected by Dr. A. Kahma from the Varala pegmatite, about 30 km. east-south-east of Tampere in south-west Finland, yielded an age of 1,810 ± 120 m.y. Shortly afterwards, however, Parwell and Wickman[16] announced a number of uncorrected chemical ages, varying from 1,700 to 1,810 m.y., for uranium-bearing minerals from late Svecofennian pegmatites in the neighbourhood of Stockholm. Isotopic analyses of the respective leads

are in progress; but meanwhile the above convergence of evidence suggests that the Svecofennian pegmatites are very much older than those of the Arendal, Lewisian and Grenville provinces.

Apart from some of the potash determinations, the experimental results recorded in Table 1 were carried out at the University of Toronto with equipment for which grants were received from the National Research Council, Geological Survey of Canada, Research Council of Ontario and Imperial Oil, Ltd. We are indebted to Dr. G. L. Cumming and Dr. R. D. Russell, who made the mass spectrometer analyses; to Mr. K. Watson, Mr. W. R. Inman, Mr. H. B. Wiik and the Chemical Research Laboratory for potash analyses; and to the Carnegie Trust for the Universities of Scotland for a grant from which the cost of the Herdsman potash analyses was defrayed. Most of the specimens were specially collected for this investigation, and our thanks are extended to the various geologists who have co operated in this joint enterprise.

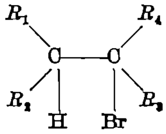
# A CORRELATION BETWEEN THE RATES OF UNIMOLECULAR PYROLYSIS OF ALKYL HALIDES IN THE GASEOUS PHASE AND S<sub>N</sub>1 RATES IN SOLUTION

By DR. ALLAN MACCOLL
**William Ramsay and Ralph Forster Laboratories, University College, London, W.C.1**
AND
DR. P. J. THOMAS
**Department of Physical Chemistry, Imperial College of Science and Technology, London, S.W.7**

IT has been found that for molecules of the type



the major factor determining the rate of unimolecular dehydrobromination is the environment of the C—Br bond. The following relative rates (Table 1*a*) and activation energies (Table 1*b*) for a series of bromides in which the C—Br and C—H bonds range from primary to secondary to tertiary amply demonstrate this fact.

Table 1*a*

| C—H | C—Br *p* | C—Br *s* | C—Br *t* |
|---|---|---|---|
| *p* | 1 (ref. 1) | 170 (ref. 4) | 32,000 (ref. 6) |

| *p* | 53·9 | 47·8 | 42·2 |
| *s* | 50·7 | 43·8 | 40·5 |
| *t* | 50·4 | — | 39·0 |

In Table 1*a*, the rates are given relative to ethyl bromide (taken as 1) at 380° C., and Table 1*b* shows the corresponding activation energies (in kcal.). The small effect of variations in the C—H bond type is shown again by the work of one of us (P. J. T.) on 4-bromo-pentene-1, for which, despite the allylic weakening of the C—H bond concerned in the elimination, the rate is comparable to that of *sec*-butyl bromide.

That no simple relationship exists between the activation energy for the elimination of HX ($E_{HX}$) and the homolytic bond dissociation energy $D(R$–X is shown in Table 2.

Table 2

| | $C_2H_5Br$ | *sec*-$C_3H_7Br$ | *tert*-$C_4H_9Br$ |
|---|---|---|---|
| $E_{H\text{-}Br}$ | 53·9 | 47·8 | 42·2 |
| $D(R\text{-}Br)$ (ref. 12) | 67·2 | 67·6 | 63·8 |
| $D(R^+Br^-)$ (ref. 13) | 183·7 | 156·3 | 140·3 |
| Rate ratio | 1 | 170 | 32,000 |

| | $C_2H_5Cl$ | *sec*-$C_3H_7Cl$ | *tert*-$C_4H_9Cl$ |
|---|---|---|---|
| $E_{H\text{-}Cl}$ | 60·8 (ref. 9) | 50·5 (ref. 10) | 41·4 (ref. 1 |
| $D(R\text{—}Cl)$ (ref. 12) | 80·9 | 82·2 | 78·3 |
| $D(R^+Cl^-)$ (ref. 13) | 192·8 | 166·3 | 150·2 |
| Rate ratio | 1 | 178 | 19,500 |

Also included are the heterolytic bond dissociati energies $D(R^+X^-)$, that is, those for the proce

$$RX \rightarrow R^+ + X^-$$

in the gaseous phase. These latter two sets of figur when compared with the rates relative to the eth compounds or the activation energies allow two co clusions to be drawn. The first is that a comm mechanism is involved in the dehydrohalogenati of the bromides and of the chlorides. The second that, while there is no correlation between t energies or free energies of activation and the hom lytic bond dissociation energies, there is a cle correlation with the heterolytic bond dissociati energies.

A possible explanation of the strong dependen of the rate upon the nature of the carbon atom the C—X bond lies in the assumption that activati consists primarily of an elongation with polarizati of the C—Br bond with some assistance from polarized C—H bond. That homolytic C—H fissi is not part of the rate-determining process is sho by the observation that 4-bromo-pentene-1 deco poses at about the same rate as *sec*-butyl bromid despite the fact that a β-allylic hydrogen atom nvolved and that a conjugated pentadiene is formed n the reaction.

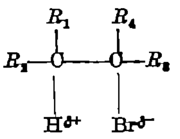
The polybromo ethanes form another interesting eries of compounds. Thus it has been established y P. T. Good (unpublished work) that whereas thylidene bromide decomposes faster than ethyl romide, with ethylene dibromide the reverse is true. Partial confirmation of this behaviour is given by he work of Barton and Howlett[9], who observed that he rate of decomposition of ethylidene chloride is reater than that of ethyl chloride. Further halogen ubstitution on an α-carbon atom increases the rate, whereas such substitution on a β-carbon atom lecreases it.

Thus, the following rate relationships have been bserved for the elimination of hydrogen bromide :

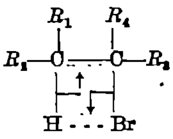
$$(CH_3)_3C.Br > (CH_3)_2CHBr > CH_3CH_2.Br$$
$$CH_3CHBr_2 > CH_3CH_2Br > CH_2Br.CH_2Br$$

The first is well known to be the order characteristic of $S_N1$ or $E1$ rates in solution, and the second is the heoretical order, not yet verified, for unimolecular ates in a polar solvent. A qualitative analogy thus xists between $S_N1$ or $E1$ rates in solution and the unimolecular rate of elimination of hydrogen bromide. The behaviour of the first series with respect to the $S_N1$ and $E1$ mechanism has been explained in terms of the electron-releasing power of the methyl groups ttached to the α-carbon atom which facilitates the ormation of Br⁻. The role of the polar solvent in uch a mechanism is essentially the stabilization of he highly polar transition state.

It is now suggested that the β-hydrogen atom in he unimolecular elimination mechanism plays somewhat the same part as the solvent in the $S_N1$ and $E1$ mechanisms of reactions in solution. Thus the ransition state may be represented by :



or



he β-hydrogen atom stabilizing the potential Br⁻, ust as the solvent does in solution. The situation nay be represented graphically, as in Fig. 1. Curve a) represents the potential energy for dissociation nto $R^+$ and Br⁻, from an excited electronic state ; urve (b), the dissociation into atoms from the ground tate. Curve (c) represents the hypothetical stabilzation of the $C^+Br^-$ system by the β-hydrogen atom, eading eventually to an olefin and hydrogen bromide. As a result of the intersection of curves (b) and (c), a plitting will occur, leading in particular to curve (d), which represents the reaction path.

Further confirmation of the views advanced here comes from qualitative observations on the system $CH_3OCHClCH_3$. This substance[14] undergoes reaction nder $S_N1$ conditions more rapidly than *tert*-butyl hloride by a factor of at least $10^6$. In the gas phase, lecomposition sets in some 50° lower than for *tert*-utyl chloride.

It is suggested that the ideas developed here may e applied to other gas-phase eliminations. Although nly *tert*-butyl and *tert*-amyl alcohols[15] have so far een investigated, it is interesting to note that Brearley, Kistiakowsky and Stauffer observed that, or both the chlorides and the alcohols, the ratio of he rates of the *tert*-amyl to that of the *tert*-butyl compound was 2·35. In the case of the bromides, the ratio in the range of temperatures experimentally studied (~ 250° C.) was 2·34. The close agreement in the three cases is strongly suggestive of a common mechanism. Further, at 25° C., in '80 per cent' aqueous ethanol, the observed ratios of first-order constants (*tert*-amyl/*tert*-butyl) are for the chlorides 1·76 ; bromides, 1·57 ; and iodides, 1·93[16]. This provides additional evidence of the analogy between the $S_N1$ and $E1$ mechanism and the unimolecular elimination of hydrogen chloride and hydrogen bromide. Although the position with respect to the iodides is far from clear, the results are capable of interpretation on the basis of competitive mechanisms, one involving the fission of the C—I bond, the other involving elimination of hydrogen iodide.

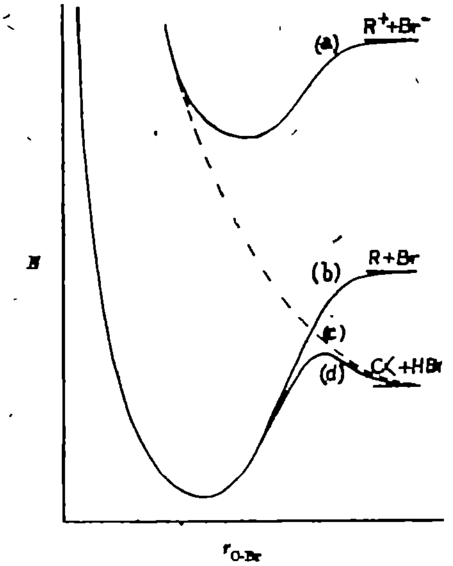


Fig. 1

Our present conclusion from this work, which is being extended, is that important modification is needed in the current view that all gas reactions are in principle homolytic, and accordingly require concepts of mechanisms and of structural effects which are strongly differentiated from those applying to heterolytic reactions in polar solvents.

We wish to thank Profs. E. D. Hughes and C. K. Ingold, and Dr. P. B. de la Mare and Mr. C. A. Vernon for many helpful discussions. We also acknowledge with thanks the communication of results, prior to publication, by Mr. P. T. Good.

## Paramagnetic Resonance Absorption of Ferrihaemoglobin and Ferrimyoglobin Derivatives

MAGNETIC susceptibility measurements on ferrous and ferric haemoprotein complexes have led to the bonding of the iron being classified as 'essentially ionic' or 'essentially covalent', as with other co-ordination compounds containing elements of the first transition series[1]. Ferrohaemoglobin, acidic ferrihaemoglobin and its fluoride complex are in the first category, oxy- and carbonmonoxy-ferrohaemoglobin and the azide and cyanide complexes of ferrihaemoglobin are in the second. The electronic state of the iron has accordingly been thought strictly comparable to that in the Fe$^{2+}$ and Fe$^{3+}$ aquo-ions and that in the Fe(CN)$_6^{4-}$ and Fe(CN)$_6^{3-}$ complex ions respectively, since the corresponding magnetic susceptibilities are very similar.

Another manifestation of the magnetic properties is revealed by paramagnetic resonance absorption measurements from which $g$-values may be obtained, quantities related to the magnetic moment, the magnitudes of which for a compound of a first transition element depend not only upon the quantum number $S$ but also the total orbital quantum number $L$ and the symmetry around the ion. The ferric ion, which is in an orbitally singlet state ($L = 0$), has[2] one $g$-value of 2·0. Acidic ferrihaemoglobin and its fluoride complex, in which the iron has hitherto been assumed to be bound by essentially ionic bonds on the basis of paramagnetic susceptibility measurements, were therefore expected also to have $g$-values of 2·0. Using wet solid specimens, measurements at liquid-air and liquid-hydrogen temperatures have, however, given identical $g$-values of 5·90 ± 0·05 for both derivatives; these are very similar to that obtained for haemin[3].

Since the observation of such high $g$-values in polycrystalline specimens was quite unexpected, the measurements were repeated at as many frequencies as possible in order to check that zero-field splitting was not responsible for the position of the line. Determinations were made at 3·2 cm., 1·25 cm., 1·0 cm., 8 mm. and 6 mm. wave-lengths, and the results are summarized in Fig. 1. The fact that all the points for both haemin and acidic ferrihaemoglobin lie on straight lines passing through the origin show conclusively that true $g$-values are being measured. A slight asymmetry in the shape of the line was noted which indicates that the $g$-value spreads to somewhat lower values; but from intensity considerations this variation would appear to be small. It is hoped to carry out measurements on single crystals to obtain the precise values for the variation. It is quite clear, however, that the electronic state of the iron is entirely different in these 'ionic' complexes from that of the gaseous or aquated Fe$^{3+}$ ion.

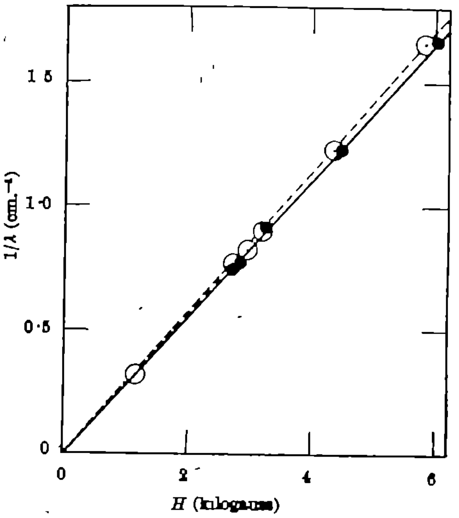

Fig. 1. Plots of reciprocal wave-length against magnetic field for haemin (ref. 3) (open circles) and acidic metmyoglobin (full circles), from which $g$-values of 6·00 ± 0·05 and 5·90 ± 0·05 respectively have been obtained

Measurements have also been made on the azide and cyanide complexes of ferrihaemoglobin, in which the bonding of the iron is classified as essentially covalent. A well-defined variation of $g$-value from 2·2 to 2·8 was obtained for the former, but the latter gave very weak absorption. No measurements have yet been made in the range $g < 2$, but the results for the azide complex show that there is a significant quantitative difference between a 'covalent' haemoprotein complex and a 'covalent' inorganic co-ordination complex such as the ferricyanide ion, which has $g$-values[4] along the three axes of 0·94, 2·18 and 2·30.

Very similar absorption was observed for the corresponding ferrimyoglobin derivatives, and identical $g$-values were obtained. These results show, in a more direct manner than the magnetic susceptibility values, that no appreciable intramolecular interaction, in the sense of a coupling between the magnetic moments, occurs between the iron atoms in the recrystallized ferrihaemoglobin used for these measurements.

*Note added in proof.* Preliminary measurements on single crystals of acidic ferrihaemoglobin, kindly supplied by Dr. V. Ingram, of the Cavendish Laboratory, indicate that the high $g$-value of about 6 corresponds to $g_{\perp}$, that is, in the plane of the haem. The asymmetry of the line reported above is due to a $g_{//}$ value, that is, along the axis perpendicular to the haem, of less than 3, probably about 2·5.

## Anomalous X-Ray Scattering at Wave-lengths far from an Absorption Edge

IT has been predicted recently[1] that the anomalous attering of X-rays found close to an absorption dge would make direct Fourier synthesis methods pplicable to non-centrosymmetrical crystals. In his procedure isomorphous substitution would be tilized for the determination of the absolute values f the phase angles of the scattered radiation; the hase angles are simply calculated from the structure ector triangle with sides $F_1$, $F_2$ and $F_1 - F_2$, where $_1$ and $F_2$ denote the structure factors of the two somorphous compounds while $F_1 - F_2$ is the difference in contribution of the heavy and light atom. he signs of the phase angles should then in principle e determinable from the effect of anomalous scattering on the intensities.

In the course of experiments designed to test the sefulness of the above scheme, the very interesting bservation has been made that anomalous scattering ffects can be observed at wave-lengths far from the bsorption edges of any heavy atom in the crystal. he amino-acid l-tyrosine was selected as the unnown test structure to be used, in the form of the somorphous hydrochloride and hydrobromide. The vell-formed crystals obtained were assigned to the on-centrosymmetric monoclinic $P2_1$ space group. ero-layer Geiger counter observations with monohromatized copper radiation were collected from ylindrically ground specimens with either the *a* or *b* rystal axis parallel to the cylinder axis. The unexpected finding was made that $I_{0kl} \neq I_{0\bar{k}\bar{l}}$; the observed difference averaged about 8 per cent but eached 50 per cent in an extreme case. Some typical omparisons are made in Table 1.

Table 1

| | Tyrosine hydrochloride ($\Delta f'' = 0\cdot83$) | | | Tyrosine hydrobromide ($\Delta f'' = 1\cdot1$) | | |
|---|---|---|---|---|---|---|
| *hkl* | $F_{0kl}$ | $F_{0\bar{k}\bar{l}}$ | $\Delta(F'')_{\text{calc.}}$ | $F_{0kl}$ | $F_{0\bar{k}\bar{l}}$ | $\Delta(F'')_{\text{calc.}}$ |
| 020 | 570 | 641 | 66 | 725 | 895 | 110 |
| 002 | 73 | 73 | 0 | 439 | 459 | 0 |
| 011 | 220 | 207 | 21 | 98 | 59 | 31 |
| 041 | 354 | 298 | 47 | 1,330 | 1,240 | 50 |
| 052 | 93 | 113 | 23 | 665 | 691 | 31 |
| 035 | 178 | 147 | 30 | 195 | 189 | 40 |
| 016 | 221 | 231 | 17 | 320 | 341 | 23 |
| 055 | 2 5 | 5 8 | 0 | 22 2 | 22 9 | 0 |
| 027 | 288 | 269 | 26 | 960 | 876 | 22 |
| 0.2.11 | 100 | 108 | 0 | 610 | 610 | 0 |

t is noteworthy that $I_{00l} = I_{00\bar{l}}$ for the [100] zone neasurements and $I_{h0l} = I_{\bar{h}0\bar{l}}$ for the entire [010] one.

Tests were then made on a number of other rystals, which quickly established that the above ondition was observed only when a heavy atom and polar axis were involved. Tests were made with nolybdenum and with chromium radiation, and non-equivalences of the same order of magnitude were ound. A final decisive experiment was carried out vith rubidium hydrogen tartrate[2], a compound for vhich similar intensity differences with exciting adiation have been found and have been explained s due to anomalous scattering. This compound gave on-equivalent intensities with chromium radiation vhich were parallel in every respect, but smaller in nagnitude than those observed with exciting adiation.

The magnitude of the effect is great enough to allow t to be seen clearly on photographs in the case of some eflexions. The surprisingly large effect observed for tyrosine hydrobromide with copper radiation must clearly be due to excitation of the *L*-electrons even though the absorption edge is at $\lambda \cong 8$ A., since the *K* absorption edge at $\lambda \cong 0\cdot92$ A. cannot contribute. Assuming all eight *L*-electrons contribute, a prediction of the magnitude of the effect on the basis of Hönl's[3] calculations leads to satisfactory agreement with experiment. Table 1 gives such a comparison; a value of $\Delta f''$, the imaginary component of the bromine scattering amplitude, of 1·1 was used. In the case of chlorine, the *K* absorption edge is at $\lambda \cong 4\cdot4$ A., and with copper radiation the principal effect would be expected from the *K*-electrons. Using a value of $\Delta f'' = 0\cdot83$ taken from James[4], satisfactory agreement with experiment is again obtained, as can be seen from Table 1. Thus it is clear that the initial feeling of surprise that one feels at such a wholesale failure of Friedel's law is not justified.

The significance of the above findings for direct structure determination by Fourier synthesis in the non-centrosymmetrical case is at once apparent. In the case of tyrosine hydrochloride and hydrobromide, a direct solution of the structure has been readily obtained using no structure hypotheses, but only the information contained in the measurements themselves. The results of this investigation will appear in due time.

The success of the method is clearly dependent on accurate intensity measurements, preferably those made with a Geiger counter; however, the most commonly available radiations can successfully be used.

## Nuclear Spin and Hyperfine Structure of Radioactive Silver, $^{111}_{47}$Ag

AN atomic beam magnetic resonance apparatus[1] has been constructed, and the nuclear spin and hyperfine structure separation of the $^2S_{1/2}$ ground state of silver-111, of half-life 7·5 days, have been measured. Also a new value of $g_J$ for silver has been derived from the experimental results.

The nuclear spin is $\frac{1}{2}$ in units of $h/2\pi$, which confirms the value of McGinnis[2] and of Lemonick and Pipkin[3]. The transition ($F = 1 \longleftrightarrow 0, m_F = 0 \longleftrightarrow 0$), which is independent of the field to the first order, was observed at a magnetic field of 2·3 gauss, giving a value for the hyperfine structure separation of $|\Delta\nu| = 2,204\cdot54 \pm 0\cdot05$ Mc./sec. This agrees with the tentative value $2,180 \pm 100$ Mc./sec. given by Lemonick and Pipkin[3].

The transition ($F = 1, m_F = 1 \longleftrightarrow 0$) was observed at several fields up to 263 gauss, from which was calculated

$$g_J(\text{Ag}, {}^2S_{1/2}) = 2\cdot00242 \pm 0\cdot00011,$$

assuming $\mu_I$ ($^{111}$Ag) $< 0$. The choice of a positive sign for the nuclear magnetic moment of silver-111 leads to a value of $g_J$ (2·00258) outside the limits of error of the value $g_J(\text{Ag}, {}^2S_{1/2}) = 2·00224 \pm 0·00020$ given by Wessel and Lew[4]. On this evidence we conclude that the nuclear magnetic moment is negative.

With the values of the hyperfine structure of silver-107 and silver-109 given by Wessel and Lew[4], the ratios

$$\frac{\Delta\nu(^{111}\text{Ag})}{\Delta\nu(^{107}\text{Ag})} = +\ 1·287278 \pm 0·000059$$

$$\frac{\Delta\nu(^{111}\text{Ag})}{\Delta\nu(^{109}\text{Ag})} = +\ 1·115127 \pm 0·000048$$

are found. These are sufficiently accurate for a determination of the hyperfine structure anomaly (expected to be about 0·5 per cent), when the nuclear magnetic moment of silver-111 can be measured precisely at some future time. At present we can only give a value $\mu_I$ ($^{111}$Ag) = − 0·145 n.m. accurate to about 1 per cent.

The details of the experiment are to be published elsewhere.

We are indebted to the Royal Society for a grant from the Paul Instrument Fund towards the cost of the apparatus.

## Structure of Polyglycine

Nearly twenty years ago, Meyer and Go[1] described the X-ray diffraction powder photograph of some glycine peptides, and found that different photographs were obtained from polyglycine according to the method of preparation. When the polymer was made by decomposition of the N-carboxy glycine anhydride in the presence of pyridine, reflexions corresponding to 4·4 A. and 3·45 A. were observed; but the same polymer precipitated by water from aqueous lithium bromide solution gave a photograph in which a reflexion at 4·15 A. was predominant. Subsequent observations[2-4] have related to the first form, which may be produced by casting from solution in dichloracetic acid or in trifluoracetic acid. It will be convenient to refer to this form as polyglycine I, and to the form characterized by the 4·15-A. reflexion as polyglycine II.

It has recently been found[5] that the two forms have different infra-red spectra. Whereas polyglycine I is a typical β-polypeptide, with absorption bands at 1,630 cm.$^{-1}$ (C=O) and 1,530 cm.$^{-1}$, polyglycine II has bands at 1,648 cm.$^{-1}$ (C=O) and 1,558 cm.$^{-1}$. The C=O mode of the second form, therefore, does not fall within the range found for either α- or β-synthetic polypeptides[6]. Other bands enable polyglycine I and II to be distinguished; the most convenient are at, respectively, 1,015 cm.$^{-1}$ and 1,026 cm.$^{-1}$. Under suitable conditions of precipitation, which were found by examining the infra-red spectra, polyglycine II can be obtained in a pure form. The X-ray diffraction diagram of this pure form is shown in Fig. 1. It would appear that Meyer and Go's polyglycine (shown in Plate II of their paper) was a mixture of I and II.

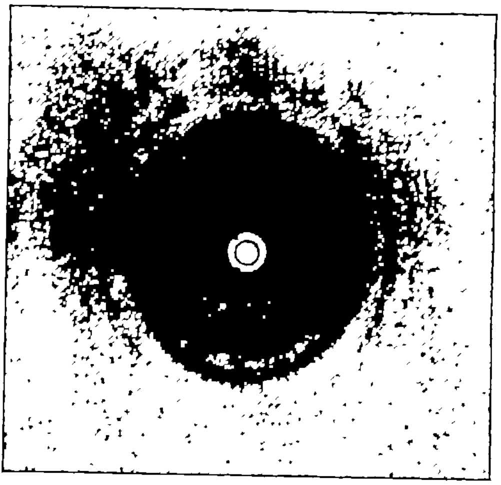

Fig. 1

The diffraction pattern of polyglycine I contains a reflexion at a spacing of 1·16 A. A reflexion occurring at this spacing in other β-polypeptides and silks is the 006 reflexion (c is the molecular chain axis), and if polyglycine consists of extended polypeptide chains, strong reflexion would be expected very near this spacing whether the chains were packed in a rectangular or a triclinic cell[4]. We have found no reflexion corresponding to a spacing in the neighbourhood of 1·16 A. in polyglycine II, showing that the two forms do not arise from different ways of packing extended (or nearly extended) chains; the chains in the two forms must have different configurations. This also follows from consideration of the relative intensities of the rings in the two powder photographs. The relative intensities of the equatorial reflexions from a given crystalline arrangement of extended (β) chains may be estimated from optical transforms of the c-axis projection. It is readily seen that the 3·45-A. reflexion should be somewhat stronger than the 4·4-A. reflexion if, following Astbury[6], these are indexed as 010 and 100 respectively; and in fact this is observed in polyglycine I, the β-form. However, to interpret polyglycine II in terms of a nearly extended chain would require us to take the very intense 4·15-A. reflexion as 100, with the next strongest (3·1 A.) as 010, in order to get a reasonable molecular packing. The predicted intensities for such an arrangement are quite different from those observed.

The very intense 4·15-A. reflexion appears to come from planes which are parallel or nearly parallel to the fibre axis (see below). The high intensity shows that the electron density has a very marked periodicity of 4·15 A., and it is reasonable to conclude that this is the separation of layers of polypeptide chains, possibly in hexagonal array. The α-helix (which would give hexagonal packing) can be excluded, since with such close approach of chains the density would be impossibly high (more than 3 gm./c.c.).

Of the various structures which have been proposed for polypeptide chains, only two appear to provide reasonable values for the density, and optical transforms of these, the 2·2$_7$ helix[7] and the unrotated parallel polar sheet[8], have been examined. Space-filling models of the polar sheet show that interplanar distances of about 4·15 A. and 3·6 A. occur; but the optical transform shows that these reflexions should appear with comparable intensities, whereas the X-ray photograph shows a very weak ring corresponding to 3·8 A. and an overwhelmingly strong 4·15-A. reflexion (see Fig. 1). It seems, therefore, unlikely that a polar sheet structure is present.

Transforms of the $2 \cdot 2_7$ helix based on a 10$\bar{1}$0 reflexion of 4·15 A. lead to a prediction of intensities in general agreement with those observed in the X-ray powder photograph; but the details are not in agreement. In particular, no reflexion corresponding to the residue repeat 2·75 A. is seen. In a triclinic cell, such a reflexion would not be expected, since there is no reciprocal lattice point corresponding to 2·75 A.; but clearly such a possibility cannot be examined profitably until a fibre photograph is obtained. The density predicted for such an arrangement of $2 \cdot 2_7$ helices is 1·67 gm./c.c., which is considerably higher than the measured density of polyglycine II (1·43 gm./c.c.).

The methods by which polyglycine II may be prepared suggest that it might be an intra-chain hydrogen-bonded structure. Casting from any solvent such as dichloracetic acid invariably produces a predominance of the β-form, and we have found that precipitation from solution is generally necessary in order to prepare form II. The only method we have found which produces coherent films of form II is to prepare films in the presence of a salt. The polymer is dissolved in a mixture of formic acid, and calcium chloride and the formic acid dried off. The calcium chloride may then be washed out with alcohol, leaving a spongy film. It appears likely that the effect of the salt is to reduce the probability of intermolecular hydrogen bonding. If films made in this way are rolled, a small amount of orientation of form II is obtained which indicates that the 4·15-A. reflexion is probably equatorial rather than meridional. In addition, if the films, which from infra-red and X-ray examination are found to contain no β-material, are rolled hot, a small amount of doubly oriented β-material is produced. The β-material is quite well oriented, the mean direction of the chain axis lying in the direction of rolling; a similar orientation is observed in the α → β transformation in other synthetic polypeptides.

These facts suggest very strongly that the molecules of form II are folded and that on rolling a number are pulled out into the β-form. It would appear that here we have strong evidence for a configuration of the polypeptide chain which is outside the range of structures hitherto accepted.

No evidence of the α-helical form of polyglycine has been found, except observation of parallel dichroism of the NH-band in a specimen which had been stretched in polystyrene[5]. Recent observations suggest that this may really be a 'cross β' structure, since the C=O band accompanying the dichroic NH band has the β- rather than the α-frequency.

The fact that the 1,015 cm.$^{-1}$ band of polyglycine disappears when the β-form is converted into form II shows that the absence of this band in the spectrum of polymers containing glycine is no proof that the structure is one in which there are no glycyl–glycyl bonds. Especially in the case of alanine–glycine copolymers, and in silks, the possibility that frequency changes are caused by change of molecular configuration must be considered. Since criteria for the recognition of α- and β-forms have now been known for some years[6], we consider that these possibilities should be considered before conclusions on the chemical constitution of silk are based on the appearance or absence of bands in the spectrum[9]. The work we have here reported shows that there exists, in polyglycine at least, a configuration of the polypeptide chain other than the α-helix and the normal β-forms.

## Positive-Point D.C. Corona

With a point-to-plane gap geometry, a visible (corona) discharge can occur at much lower values of applied gap voltage than those necessary to cause spark breakdown. Such a positive-point d.c. corona discharge in room air has been studied by recording the light emitted with an 11-stage photomultiplier. The output from the photomultiplier was delayed, amplified by 'distributed' amplifiers[1], and displayed on a high-speed cathode ray oscilloscope. The time base of the oscilloscope was triggered by the output of light through a separate photomultiplier, distributed amplifier and thyratron trigger circuit.

The discharge in room air could occur in two distinct forms: (1) a filamentary form which showed discontinuities of current and light throughout a wide range of applied voltage (that is, 'burst pulses', 'pre-onset streamers' and 'pre-breakdown streamers'); (2) a diffuse glow discharge, in which the mean gap current, measured by a galvanometer, was less (~ 40 per cent) than in the filamentary discharge for the same gap geometry at a given value of applied voltage. The spark breakdown voltage was higher and the mean gap current immediately preceding breakdown was lower for the glow discharge than for the filamentary discharge for the gap geometries investigated. The glow discharge showed discontinuities of current and light only over a narrow range of applied voltage (~ 200 V.) near onset; these discontinuities were presumably associated with a 'Geiger' counting action in the gap.

The filamentary form of discharge was investigated. The discontinuities of current and light were observed to be pulses of short duration. The current pulses were similar to those observed by other workers[2,3]. A light pulse was associated with each current pulse. The light pulses occurred about $5 \times 10^{-8}$ sec. after the current pulses, as shown by their relative displacements from the initiation of the oscilloscope time-base. The instrumental part of this delay was

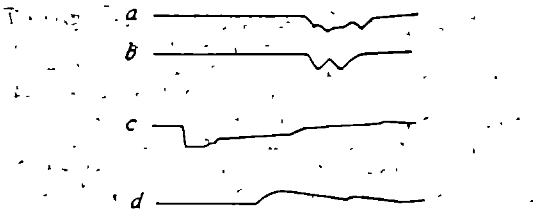

Fig. 1. Tracings of typical pulses observed with an applied gap voltage of 16 kV.
(a, b) High-amplitude initial portion of light pulse, sweep duration 0·56 µsec.; (c) low-amplitude portion of light pulse, sweep duration 2·3 µsec.; (d) electrical pulse, sweep duration 0·56 µsec.

about $2 \cdot 5 \times 10^{-8}$ sec. The light pulses (Fig. 1) showed an initial portion of high light intensity and short duration ($\sim 6$–$2 \times 10^{-8}$ sec.), followed by a portion of lower intensity ($\sim$ 1 per cent) and relatively long duration ($\sim 10^{-6}$ sec.). The initial portions of the light pulses usually showed several irregular peaks and were identifiable with the pulses recorded by English[4] and Amin[2]. The peaks were thought to be associated with branching of the discharge, such branching apparently taking place when the discharge was operated into a weak field region. If branching of the discharge was the explanation for the peaks, then the branches did not appear to be propagated simultaneously but in rapid succession. The low-intensity portion of the light pulses corresponded to the light pulses observed by Gaunt and Craggs[5].

The spatial distribution of the emitted light was investigated by projecting an enlarged real image of the axis of the gap in the plane of the photocathode of the recording photomultiplier. Light pulses were observed from all regions of the gap. By measuring the relative displacement of the pulses along the time-axis of the oscillograms, the spatial growth of the discharge could be determined. The results shown in Fig. 2 were obtained with an applied voltage of 16 kV., a tungsten point of radius of curvature 0·228 mm., a gap-length of 3 cm., an aluminium plane cathode of 15 cm. diameter and a resistance of 200,000 ohms in series with the point electrodes. The effective sampling area was 3 mm. in diameter.

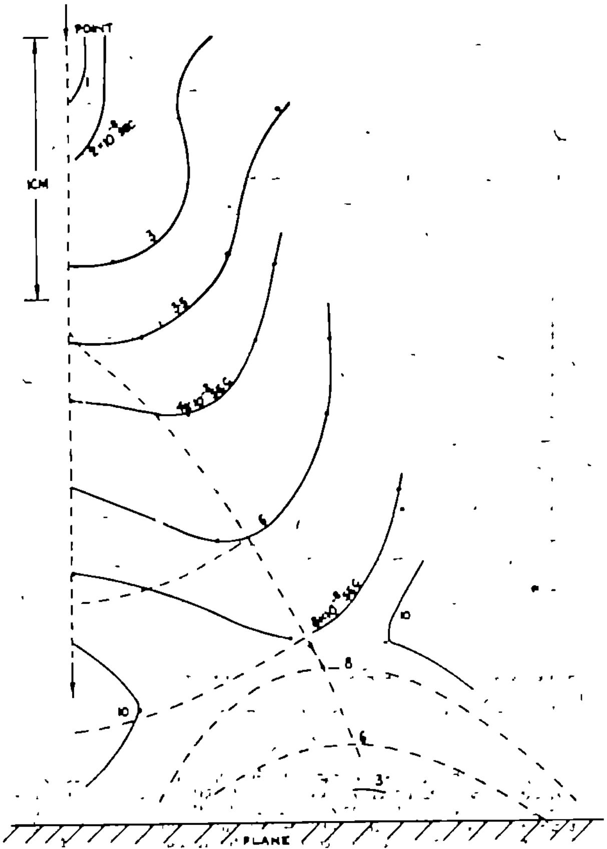

Fig. 2. Observed spatial growth of 'breakdown streamer'. Point radius 0·228 mm.; applied voltage 16 kV.

The discharge was propagated from the point steadily and with constant luminosity for a distance of about 1 cm., after which the luminosity decreased and branching of the discharge was thought to occur. About three, but up to five, branches were possibly associated with each discharge sequence, and about one in three branches was estimated to continue to be propagated along the axis. When branches were deflected from the axis, possibly by space charge in the gap, then a visible discharge was observed to grow from the plane cathode. Presumably the visible discharge from the cathode was caused by photo-electrons from the cathode causing excitation, even though moving in a very low field ($x/p \sim 1 \cdot 4$ volts/cm. per mm. mercury pressure).

The form and growth of the individual events in the filamentary discharge were very similar to the type of growth which contributed to the founding of the streamer theory, where the principal secondary mechanism in the discharge was considered to be photo-ionization in the gas. Most of the observations could be explained satisfactorily by the streamer theory[6]. It is hoped to publish elsewhere a full account of the results and their implications.

I thank Prof. J. M. Meek, in whose laboratories this work was carried out, Dr. J. D. Craggs for advice, the University of Liverpool for the award of a Munitions Committee Fellowship, and the British Electrical and Allied Industries Research Association for further generous financial assistance.

## Ion-Exchange Chromatography in Alcohol

IN the technique of ion-exchange chromatography, the order in which compounds are eluted from a column depends basically upon differences in their ionization constants; but other factors modify and in many instances reverse the expected order[1]. This is illustrated in Fig. 1, where the elution peaks of a number of acids from a 'Dowex' resin are plotted against their $pK$ values. Although there is a definite correlation between acid strength and ease of elution, the points are very scattered, and in particular acids containing an aromatic group are eluted much later than would be expected on the basis of their ionization constants.

The suggestion has been made by Martin[2] that separations on all chromatograms consisting of a

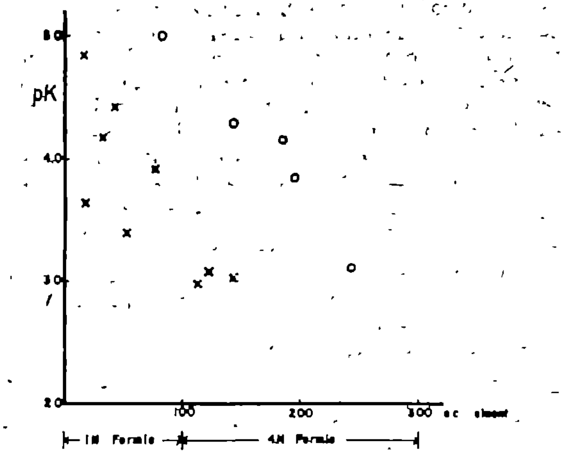

Fig. 1. Ion-exchange chromatography on 'Dowex 1-×8'. The resin was converted to the formate form as described by Busch, Hurlbert and Potter (ref. 10), and the chromatograms were run in a column 12 cm. × 1 cm., eluting with 1 $N$ and 4 $N$ aqueous solutions of formic acid. The $pK$ values of the acids were taken from the literature. Elution peaks of acids containing a benzene ring are indicated by ⊙

stationary gel phase and a moving liquid phase will be influenced by the relative solubility of the solutes in the two phases. Applied to ion exchange chromatography, this means that the rate of travel of compounds on a column should be affected by their partition coefficients, based on solubility, between the eluting solvent and the swollen ion-exchange resin. In our experiments, the eluting solvent is primarily an aqueous solution, while the gel phase, although it contains water and electrolyte, has in addition some of the characteristics of an organic solvent imparted to it by the polystyrene backbone, which makes up about half the weight of the hydrated gel[8]. Therefore, acids which are relatively water-soluble should favour the moving phase and their rate of travel should be accelerated relative to water-insoluble acids. This concept helps to explain the observed retardation of acids containing an aromatic group, which as a class have limited solubility in water.

Further evidence that partition coefficients take a role in ion-exchange chromatography has been obtained by replacing the water in the eluting solvent with absolute ethanol and repeating the chromatograms with the acids used in Fig. 1. Since alcohol is also an ionizing solvent, the resulting chromatographic pattern is still apparently based on an ion-exchange process, while the shifts in elution peaks of the various acids from their previous positions can be predicted from solubility considerations (Fig. 2). Acids with a greater solubility in alcohol than in water, such as those containing a benzene ring, were eluted much earlier in the alcoholic medium, whereas the more water-soluble acids were retarded to varying degrees. Similar results have been obtained by Stein and Moore[4], who found that adding 1 per cent of benzyl alcohol to the eluent tended to increase the rate of travel of the aromatic amino-acids relative to others, while inclusion of 25 per cent propyl alcohol preferentially accelerated those possessing longer non-polar side-chains.

The position of individual acids in our chromatograms was determined by running them in small groups and identifying them by melting points and by paper chromatography in a *sec*-butanol/water/formic acid (80 : 8 : 12) system similar to one used by Kowkabany and Cassidy[5]. This system gives $R_F$ values almost identical with those obtained with the $n$-butanol/water/formic acid system of Lugg and Overall[6], but has the advantage that *sec*-butanol esterifies less readily with the formic acid.

The $R_F$ values of compounds in such an alcohol – water system are related to their partition coefficients between the alcohol and water by the equation[7]

$$\alpha = \frac{\text{concentration in water phase}}{\text{concentration in alcohol phase}} = \frac{A_L}{A_S}\left(\frac{1}{R_F} - 1\right)$$

where $A_L/A_S$, the ratio of the volumes of alcohol and water phases in the chromatogram, is a constant for any given system. From this it can be seen that compounds with partition coefficients favouring the aqueous phase will have low $R_F$ values whereas those with coefficients favouring the alcohol phase will have high $R_F$ values.

It is therefore not surprising to find that acids with high $R_F$ values ($> 0{\cdot}80$) are all eluted more readily on the ion-exchange chromatograms when alcohol is substituted for water, while acids with lower $R_F$ values ($< 0{\cdot}80$) are all retarded by the use

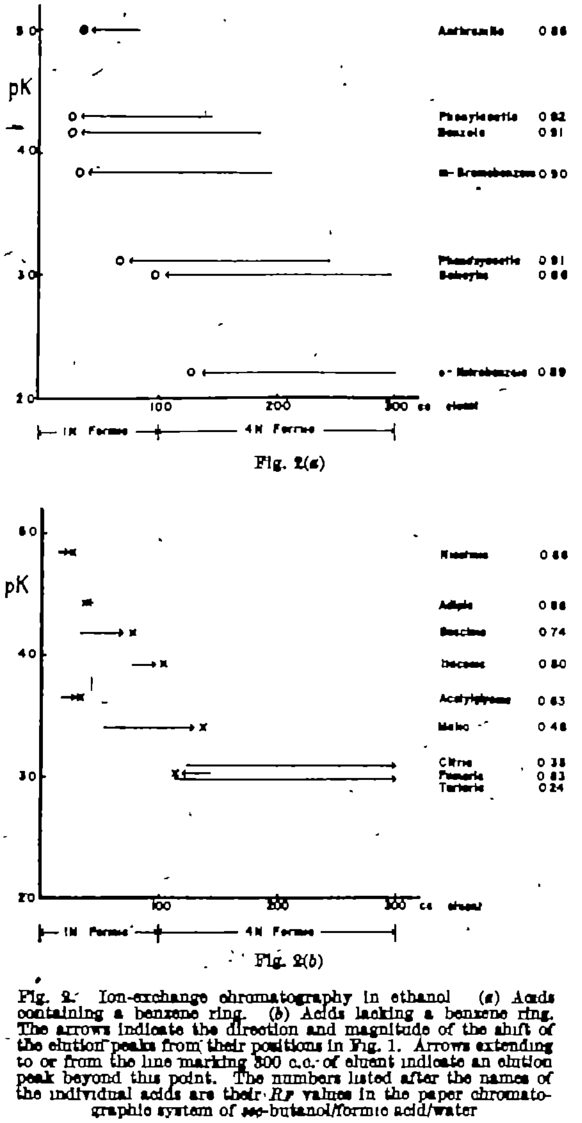

Fig. 2(a)

Fig. 2(b)

Fig. 2. Ion-exchange chromatography in ethanol (a) Acids containing a benzene ring. (b) Acids lacking a benzene ring. The arrows indicate the direction and magnitude of the shift of the elution peaks from their positions in Fig. 1. Arrows extending to or from the line marking 300 c.c. of eluent indicate an elution peak beyond this point. The numbers listed after the names of the individual acids are their $R_F$ values in the paper chromatographic system of *sec*-butanol/formic acid/water

of alcohol. This may perhaps be used as a rough method for predicting whether substances which are eluted together in an aqueous ion-exchange chromatogram could be separated by using alcohol. It should be recognized, however, that this relationship may not apply in all cases, especially since *sec*-butanol rather than ethanol was used in the paper chromatograms.

The demonstration that absolute ethanol can be used as a medium for ion-exchange chromatography promises to extend the usefulness of this technique to include many acids and bases with limited solubilities in water. The separation of long-chain fatty acids is at present being investigated in our laboratory, while Kornberg and Pricer have used chromatography in alcohol on a 'Dowex' resin for purifying a diacyl-phosphatidic acid[8], and Kennedy has used a similar method for separating phosphatides of mitochondria[9]. It appears that high recoveries can be obtained from alcohol columns, and in the experiments reported here all except one of the acids were recovered in better than 80 per cent yield although no special attempt was made to obtain quantitative recoveries (that is, the eluting solvent was removed by drying in an oven at 80° C. and some losses undoubtedly occurred due to volatility of the acids at this temperature). The use of ethanol, and of other ionizing solvents such as methanol, higher alcohols, ketones, etc., may also, by virtue of their differing solvent properties, permit separations which are not possible by other techniques at present available.

This work began during the tenure of an Agricultural Research Council Fellowship under the direction of Sir Alexander Todd at the University Chemical Laboratory, Cambridge; I wish also to acknowledge the financial assistance of the National Research Council of Canada.

## Transformation of Pentose Phosphates by Enzymes of Animal Origin

In the hexosemonophosphate oxidative cycle, pentose phosphate isomerase is required for the interconversion of ribose-5-phosphate and ribulose-5-phosphate[1], a necessary stage for the subsequent enzymic re-synthesis of hexose from pentose[2]. The enzyme has been much purified from alfalfa leaves[3], but little is known of the animal system, although the facts that xylulose-1-phosphate may be a precursor of ribose in crude liver extracts[4], and that in spleen extracts[5,6] ketopentoses other than ribulose (xylulose and 3-ketopentose) may be formed from ribose-5-phosphate, suggest that pentose transformations may be complex.

For the preparation of suitable systems, acetone-dried powders from rabbit muscle and washed red blood cells of the horse were extracted twice with ten times their weight of 0·05 *M* 'tris' buffer (tris(hydroxymethyl)-aminomethane) of *p*H 7. The extracts were heated at 55–60° C. for 5 min., freed from the resulting coagulum, and the fraction precipitated between 0·3–0·5 saturation with ammonium sulphate was suspended in water and dialysed. After rejection of the insoluble globulins, the freeze-dried material contains most of the pentosephosphate isomerase of the original extract, and remains active for months when stored at – 20°.

For the preparation of the barium salt of the ketopentose phosphate, the muscle preparation (30 mgm.) was incubated at 37° with a solution of 1 gm. (2,500 μ-moles) barium ribose-5-phosphate in 25 ml. water at *p*H 7. The ketopentose formed was measured by the Dische reaction (method of Axelrod and Jang[7]), until no further increase occurred (90 min.) and it remained unchanged at 930 μ-moles (37 per cent) for a further 30 min. After deproteinizing with perchloric acid, careful neutralization, and removal of aldoses with bromine and barium carbonate, the phosphate esters were adsorbed on a 'Dowex-1 (formate)' column and eluted with 0·1 *M* formic acid in 0·1 *M* sodium formate. By careful neutralization with barium hydroxide and precipitation with 4 vol. of ethanol, the vacuum-dried barium salt (357 mgm.) was obtained with a purity of 93 per cent based on ketopentose and 85 per cent based on ester-phosphorus content (800 μ moles ketopentose phosphate, or 32 per cent of the total initial pentose). At least 90 per cent of the total ketopentose was alkali-labile, and the rate of hydrolysis in *N* acid at 100° ($k = 5\cdot2 \times 10^{-3}$) also indicated a 5-position for the phosphate. The ratio of intensities in the orcinol reaction at 540/670 mμ we found to be 0·90–1·00 for chromatographically purified synthetic ribulose and 0·45–0·50 for xylulose. The free ketopentoses liberated by purified acid phosphatase from the above barium salt gave an intermediate value (0·55–0·60). The dephosphorylated de-ionized sugars separated sharply with 88 per cent recovery on a 'Dowex-1 (borate)' column into two peaks, of which the first (51 per cent of total ketopentose in eluate) corresponded exactly in colour reactions and position on elution with pure xylulose and the second (49 per cent) with pure ribulose. No interconversion of the pure sugars similarly processed was detectable.

The enzyme prepared from red cells gave a similar proportion (43 per cent) of total ketopentose to pentose at 'equilibrium'. But the barium salt, prepared and treated as above, had orcinol ratio 0·78, and separation on the column showed that it was substantially the ribulose ester (peak I = 10 per cent, peak II = 90 per cent of total ketopentose; orcinol ratios 0·50 and 0·90 respectively). This barium salt, when incubated with the muscle preparation, lost 59 per cent of its total ketopentose (by conversion to ribose phosphate), while the remaining ketopentose was largely the xylulose ester (peak I, 71 per cent; peak II, 29 per cent of total bromine-resistant pentoses; orcinol ratios 0·50 and 0·98 respectively).

At least one enzyme in addition to the pentose phosphate isomerase is therefore active in the muscle preparation, and converts ribulose-5-phosphate to the xylulose ester. Since no 3-ketopentose[6] formation was detected, the enzyme is presumably a type of 'waldenase', causing inversion at $C_{(3)}$ of the pentose, and resembling that recently suggested as active in *Pseudomonas hydrophila*[8].

## Modification of Response to Adrenocorticotrophic Hormone by the Simultaneous Administration of Gonadotrophic Hormones

MANY facts suggest that the adrenal–gonad relationship is an intimate one[1]. Our previous work[2] has indicated that the mouse ovary, provided it is in the luteal phase, has an effect similar to that of the adrenal cortex. While appreciating that major species differences may occur, this finding led us to commence experiments on the adrenal–gonad relationship in the guinea pig, since the urinary steroids in this species are excreted in sufficiently large amounts to be determined by routine chemical methods. It has now been shown that the response to adrenocorticotrophic hormone (ACTH) is modified by the simultaneous administration of gonadotrophins.

Ten similar experiments, each using four mature female guinea pigs, were planned as follows:

| Day of experiment | 'ACTH-only' group. Guinea pigs *A* and *B* | 'ACTH + Gonadotrophin' group. Guinea pigs *C* and *D* |
|---|---|---|
| 1 | No treatment | No treatment |
| 2, 3 | ACTH | ACTH |
| 4 to 15 | No treatment | C.G. + P.M.S. |
| 16, 17 | ACTH | ACTH + C.G. + P.M.S. |

Subcutaneous injections of 10 I.U. ACTH gel (Armour Laboratories or Wilson Laboratories) twice daily, 50 I.U. pregnant mares' serum gonadotrophin (P.M.S.; Boots Pure Drug Co., Ltd.) in distilled water once daily, and 50 I.U. chorionic gonadotrophin (C.G.; Organon Laboratories, Ltd.) in distilled water once daily, were given into separate sites. Animals were maintained on a standard diet supplemented by 15 gm. cabbage daily. Gonadotrophin treatment led to extensive ovarian luteinization. 17-Ketosteroids and 17-ketogenic steroids were determined on 24-hr. collections of urine from pairs of animals by the method of Norymberski and others[3]. Urine was collected into flasks containing a few drops of chloroform, and standing in vacuum flasks containing solid carbon dioxide. Burstein, Dorfman and Nadel[4] have shown that the main corticosteroids in normal guinea pig urine are cortisol and 6β-hydroxycortisol.

Results, expressed as the mean excretion of steroid in mgm. ± S.D./guinea pig/24 hr., are summarized as follows:

| Days of experiment | 2, 3 | 16, 17 |
|---|---|---|
| 'ACTH-only' group | | |
| 17-ketosteroids | 1·00 ± 0·43 | 0·99 ± 0·33 |
| 17-ketogenic steroids | 0·60 ± 0·27 | 0·59 ± 0·28 |
| 'ACTH + gonadotrophin' group | | |
| 17-ketosteroids | 1·00 ± 0·37 | 0·99 ± 0·37 |
| 17-ketogenic steroids | 0·62 ± 0·22 | 0·36 ± 0·16 |

The mean difference in 17-ketosteroid excretion between the first and second periods of ACTH administration was − 0·01 ± 0·22 mgm. for the 'ACTH-only' group, and − 0·01 ± 0·29 mgm. for the 'ACTH + gonadotrophin' group. These results are not significantly different ($P = 0·75$). The mean difference in 17-ketogenic steroid excretion between the first and second periods of administration of adrenocorticotrophic hormone was − 0·01 ± 0·10 mgm. for the 'ACTH-only' group and − 0·26 ± 0·15 mgm. for the 'ACTH + gonadotrophin' group. These results are significantly different ($P = 0·007$).

The urinary excretion of 17-ketogenic steroids in response to administered adrenocorticotrophic hormone has therefore been modified by treating the animals with gonadotrophic hormones, and experiments are in progress to try to elucidate this effect. Gonadotrophin treatment did not alter the urinary 17-ketosteroid response to adrenocorticotrophic hormone.

We are indebted to the Medical Research Council for a gift of adrenocorticotrophic hormone.

## Separation of Ehrlich Ascites Tumour Cells from Other Cellular Elements

THE experimental production of ascites tumours has offered an ideal material for biological, physiological and biochemical research on neoplastic cells[1]. For many problems, however, the variable admixture of leucocytes and other contaminating host cells in the ascites tumours (cf. ref. 1) implies a source of error which in certain cases may be of great importance. We have therefore investigated the possibility of reducing the concentration of such cells with the aid of a counter-streaming centrifuge, the principle of which has already been described by one of us (P. E. L.)[2]. In this centrifuge, constructed mainly for the separation of differently sized particles of the same specific density, liquid containing the particles to be separated is forced to stream through a conical centrifuge tube against the centrifugal force. Here the bigger particles down to a required size are concentrated (fraction *M*), whereas the smaller ones are carried off by the continuous stream of liquid to a second tube of a different shape where they are made to sediment (fraction *G*).

The tetraploid line of the Ehrlich ascites tumour[1] was used for the experiments. Cell samples were withdrawn from the peritoneal cavity at various intervals after inoculation. They were diluted with Krebs's phosphate Ringer solution, containing 1 per cent glucose and 1 per cent gelatine. The same solution was used as the flowing suspension medium in the centrifuge. The separation was carried on for 60 min. at 300 r.p.m. and a streaming velocity of about 0·25 ml. sec.$^{-1}$. The greatest diameter of the conical tube was 2·40 cm., and the distance between this and the theoretical point of the cone 18·0 cm., the latter being 24·0 cm. from the centre of rotation. In most experiments the cells are quite undamaged after the separation. Tumour cells and non-tumorous exudate cells were counted differentially on Papanicolaou smears as described elsewhere[3]. Some experimental figures are collected in Table 1.

Table 1. PERCENTAGE OF NON-TUMOROUS EXUDATE CELLS IN VARIOUS SAMPLES BEFORE AND AFTER CENTRIFUGATION

| Exp No. | Original suspension | Fraction | |
|---|---|---|---|
| | | *M* | *G* |
| 1 | 13·0 | 3·8 | 3·6 |
| 2 | 17·3 | 9·0 | 2·8 |
| 3 | 40·7 | 12·6 | 15·8 |
| 4 | 20·5 | 11·2 | 5·2 |

In three of the four experiments, the percentage of small cells has been reduced to about one-fourth of the original value (in one experiment to one-sixth). All cells having the same specific density, one would expect to find most of the small cells in fraction *G*; it is seen from Table 1, however, that the percentage of contaminating cells is often smaller in fraction *G* than in fraction *M*. The contaminating cells thus appear to have a higher specific density than the tumour cells.

A detailed description of the centrifuge will appear shortly in I.V.A.'s *Tidskrift för Tekniskt-vetenskaplig Forskning* (Stockholm). We are indebted to Eli Lilly and Co. for financial support.

## Comparison of Rectal and Deep Body Temperature in the Calf

IN the bovine animal as with other domestic mammals including man, the rectal temperature is generally accepted as a measure of deep body temperature, and it is widely used both in field and laboratory studies for indicating the state of thermal balance of cattle when subjected to climatic stress. Despite the possibility of thermal gradients within the rectum, as has been found in man[1], there is no obvious reason for doubting the validity of this assumption, at least as an approximation, when body temperatures are steady. However, under conditions of thermal stress, when body temperatures are rising, a constant and close relationship between rectal and deep-body temperature cannot be assumed, as there is almost certainly a delay before the temperature of the fæcal mass reaches equilibrium with that of the rectal wall. Consequently, an investigation has been made to study the validity of using rectal temperature as a measure of deep body temperature in Ayrshire bull calves, four to six months old. Cattle of this age and breed have already been used in studies of environmental physiology in a climatic chamber in this Institute[2].

A reasonable measure of average deep body temperature would seem to be that of the pooled and well-mixed venous return to the heart. Eichna and others[3] and Mather, Nahas and Hemingway[4] failed to find any temperature difference across the lungs in man and dog, and assuming this to be true also of the bovine, the temperature of the blood leaving the left side of the heart should be a valid measure of both deep body temperature and of the blood supplying the temperature-regulating centre in the brain. For this reason, and because the temperature of the well-mixed venous blood in the pulmonary artery is difficult to measure without extensive surgery, the temperature of the free-flowing arterial blood in the bicarotid trunk was compared with rectal temperature.

A fine copper-constantan thermocouple, threaded into a narrow polyvinyl chloride plastic tube, sealed at the couple end, was introduced into the right carotid artery by means of aseptic surgery. The tube was passed down the inside of the artery until the thermocouple junction was estimated to lie in the bicarotid trunk. Five animals were used, and although on examination several days later an embolism was invariably found at the point of entry of the thermocouple wires into the artery, the junction was found to be lying in free-flowing blood passing up the left carotid artery. The leads were brought out through a stab wound in the skin lateral to the main incision, and terminated on a 'Perspex' button sewn on to the skin over the stab wound. A protective cap was then fitted over the button, and this allowed the animal free movement in the byre. Recovery was complete in three to four days, when the animal appeared to be normal. The calf was then placed in the climatic chamber for periods of up to 6 hr. at 20°, 30° and 40° C. at a constant low humidity (17 mgm./l. absolute humidity), and at 35° and 40° C. at a constant high humidity (7 mgm./l. saturation deficit). During the experiment, the protective cap was replaced with a cap containing copper and constantan contacts from which leads were attached to the temperature-measuring system which has already been described[2,5]. Rectal temperature was expressed as the average of almost simultaneous readings from four thermocouples each 2·5 cm. apart, the deepest being 15 cm. from the external anal sphincter. Only slight and random variations occurred between the temperatures measured by the rectal thermocouples at different depths of insertion. Measurements of rectal and carotid temperatures were taken every 5 min.

In all five animals, the carotid blood temperature was 0·1–0·3 deg. C. below that of the rectum at every low-humidity exposure. This difference remained fairly constant for any one animal at any one environmental temperature, whether body temperatures were relatively steady or were slowly climbing (Fig. 1). At the environmental conditions of 35° C. and high humidity, when body temperatures were rising, a difference between carotid and rectal temperatures remained, though in some instances the difference was less than that noted before the humidity was raised (Fig. 2A). At 40° C. and high humidity,

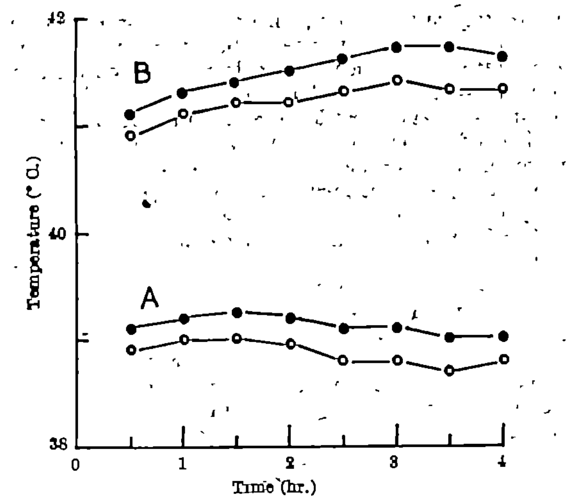

Fig. 1. Rectal (—●—) and carotid blood (—○—) temperatures of a calf while it was subjected to environmental temperatures of (*A*) 20° and (*B*) 40° C. Humidity was maintained at 17 mgm. water/l. in each experiment. Readings were taken at 5 min. intervals and plotted as half-hourly averages

when virtually all channels of heat loss were denied the animal and body temperature rose steeply at a rate determined by its heat production, the temperature difference disappeared and rectal and carotid temperatures became identical (Fig. 2*B*). Sometimes the carotid blood temperature was even slightly higher than that of the rectum.

The change in relationship between rectal and arterial blood temperatures when the humidity is raised at 40° C. is at least partly due to the delay in temperature changes of the fæcal mass. However, these are more extreme conditions of thermal stress than are normally encountered under field conditions, and it is concluded from these experiments that although rectal temperature is slightly above the temperature of the blood leaving the left side of the heart under any but the most adverse conditions of climatic stress, for all practical purposes pertaining to environmental studies with the bovine animal upward changes in rectal temperature in response to external heat stress indicate changes of a similar magnitude in 'deep body temperature'.

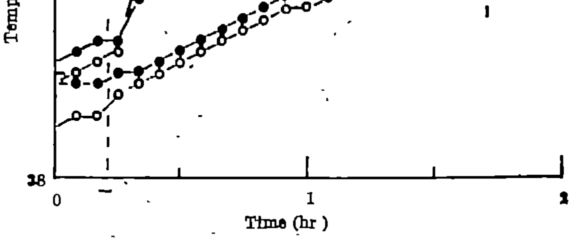

Fig. 2. Rectal (—●—) and carotid blood (—○—) temperatures of a calf while it was subjected to environmental temperatures of (*A*) 35° and (*B*) 40° C. In each experiment high humidity conditions (7 mgm./l. saturation deficit) were maintained in the room during the period within the vertical interrupted lines. The humidity was low at the beginning and end of each experiment

The 'Perspex' button and caps were designed and made by Mr. W. Nisbet of this Institute.

## Modification of the After-Potential of Single Muscle Fibres by 2:4-Dinitrophenol

INTRACELLULAR recording of electrical activity in the excised sartorius muscle of *Hyla coerulea* shows a negative after-potential of 20–25 mV. with a half-time of decay ($t_{1/2}$) of 8–12 m.sec. at 25° C. The time of recovery to resting potential level is increased to $t_{1/2}$ of 18–25 m.sec. when K+ is absent from the glucose–phosphate–Ringer medium. Successive increases of K+ concentration up to 15 *N*/1,000 cause successive shortenings of repolarization time to $t_{1/2}$ 6 m.sec.[1]. These processes are faster by one-third in *Rana catesbiana*. The after-potential of *Hyla* muscle is prolonged, also, by reduction of Na+ in the medium to 20 *M* ($t_{1/2}$ 15–20 m.sec.) or by increase of H+ to *p*H 6·5, which gives $t_{1/2}$ of 28 m.sec.

The possibility that the effect of ions upon repolarization is linked with energy supplies is suggested by Lorente[2], who used hypoxia for changing the positive after-potential of nerve. To test whether phosphate were the energy source of muscle after-potential ionic movements, 2 : 4-dinitrophenol (DNP) was added to the Ringer solution. In 20 min. 2 m*M* DNP abolished all the negative after-potential (Fig. 1,*b*). After another 10 min. it slightly reduced the resting potential to 60–65 mV. The endplate potential was not significantly altered, though the overshoot was reduced by 8–10 mV. (Fig. 1,*c*). Soaking in normal Ringer solution restored the after-potential to its previous voltage and duration. Addition of 2 m*M* DNP to a medium from which K+ was omitted prevented the normal rise of resting potential to 105 mV.; but it abolished the after-potential. In an atmosphere of nitrogen the sartorius muscle fibres were found to lose the greater part of the after-potential, and recovery followed the readmission of oxygen. Similarly, cooling the muscle to 6° C. eliminated nearly all the after-potential. The duration of the spike increased.

These findings may be interpreted as the consequences of reduction in available phosphate by the decoupling of oxidative phosphorylation, probably in the mitochondria[3,4]. Lack of oxygen would reduce phosphorylation. Active ion transfer then would be reduced. The negative after-potential would thus be the result of sodium extrusion (or possibly chloride intrusion) aided by phosphate energy, derived from oxidative sources. The effects of K+ may follow competition for transfer between K+ and the more actively transported ion.

*Heart muscle.* The intracellular record of action potentials of frog cardiac muscle cells shows pro-

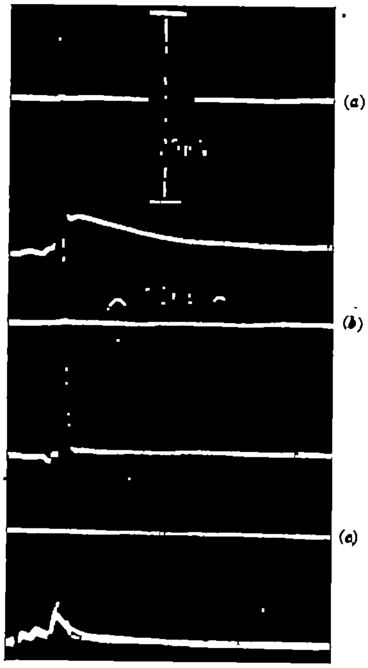

Fig. 1 (a) Intracellular muscle fibre action potential in normal glucose–phosphate–Ringer solution at 25° C. Resting potential, 85 mV ; overshoot, 46 mV.; (b) same muscle and conditions as (a) with addition of 2 m*M* 2 : 4-DNP, after 20 min. soaking The after-potential is eliminated; (c) another muscle after 30 min. in 2 m*M* DNP, at the nerve-muscle endplate, showing summation of two endplate potentials. A second sweep with action potential is superimposed. Resting potential, 60 mV.; overshoot, 38 mV.

longed depolarization when the K+ in the medium is reduced and some shortening of the depolarization time follows increase of K+ concentration up to 15 *N*/1,000. Clinically in man, this effect of K+ is detected as longer or shorter S—T intervals of the electrocardiogram in hypo- and hyperkalæmia respectively[5,6]. Reduced oxygen supply also shortens repolarization time. It seemed likely that the prolonged depolarization of the heart cell might, in part at least, be equivalent to the negative after-potential of skeletal muscle. Frog ventricular intracellular potentials were examined in the presence of 2 : 4 DNP at 25° C. The duration of the action potential was reduced from 660–700 m.sec. to 200 m.sec. without reduction in resting potential or overshoot. Longer time of action of DNP abolished the overshoot and left the ventricular action potential as a short event, occupying 90–110 m.sec. This is less than one-sixth the duration of the normal repolarization time at 25° C. and it took place without change of heart-rate. Neutral red 0·2 m*M*, when it has stained the muscle, also shortens the time-course of the action potential to one-third. It is a weak decoupling agent. The increased K+ loss from DNP-treated heart muscle[7] is probably linked with decreased sodium extrusion during repolarization. The refractory period of cardiac muscle may thus be regarded as an energy-linked ion transfer which maintains the potential near zero until half a second has passed. Five-sixths of this time of depolarization can be abolished by DNP, probably by the decoupling of phosphorylation and exhaustion of phosphate stores.

The negative after-potential of skeletal muscle appears from this evidence to be an event homologous with the greater part of the long depolarization of cardiac muscle. The two slow potentials behave in a similar fashion to K+ concentration changes and to 2 : 4-DNP. These slow potentials appear to be dependent upon phosphate energy and oxygen for the active process of ion transfer.

## Occurrence of Vertebrates in the Triassic of Israel

VERTEBRATE bones from the Triassic in southern Israel were noted by Shaw so early as 1947[1]. Further W. E. Swinton described a single nothosaurian vertebra from the same locality in 1952[2]. During my first visit in 1953, it was possible to state that more or less well preserved vertebrate bones occur abundantly in the Triassic of Wadi Raman, and a more complete fossil was found and prepared at the Swedish Geological Survey at Stockholm. After preparation, this fossil could be identified as half of the dorsal armour of the turtle-like placodont *Psephosaurus*. Hitherto, only fragments of the dorsal armour of this reptile were known, found in the lowermost part of the Upper Triassic in Germany.

The new fossil shows not only the central parts of the dorsal armour but also the incisions for the neck and the fore and hind legs, the marginal part and parts of the ventral armour.

During 1954, the number of finds of vertebrate fossils increased and hundreds of fragments were collected. Among this material there are vertebræ, teeth and bones from the extremities of numerous nothosaurian and other reptiles, five imperfect skulls, of which one belongs to *Psephosaurus* and one to a large placodont, the middle part of a nothosaurian skull and others which have not yet been thoroughly studied.

The skull of *Psephosaurus* is the most complete one. The entire occipital region, parts of the vomera area with two large teeth, the posterior part of the dorsal side of the skull, and one of the very typical jugales are well preserved. The relationship to the Placodontia is given by the teeth, and other parts of the skull also show this relationship. On the other hand, the skull of *Psephosaurus* from Israel has special characters, which show that the group of turtle-like placodonts was already distinctly separated from the other placodonts in the lower Meso-Trias.

In addition to the skull fragment, an almost complete dorsal armour of *Psephosaurus* was discovered.

The fossil-bearing layers begin with beds characterized by the ammonoid *Beneckeia*. I divide the uppermost part of the section with bones into five zones containing different types of *Paraceratites* and *Siniaceratites*[3]. The layers between the Ceratite and *Beneckeia* beds are of terrestrial origin, containing vertebrates and plant remains. The stratigraphical range of the new locality with its large vertebrate fauna begins in the deepest Lower Meso-Trias and aches the Upper Meso-Trias according to the lassification by Spath[4]. The *Psephosaurus* from Vadi Raman is therefore the oldest known of the rmoured branch of the Placodontia.

## Age of Uraninites from Dimensions of their Unit Cells

THREE years ago Dr. Wasserstein suggested in a ommunication in *Nature*[1] that "the generation by adioactive decay of smaller atoms of tetravalent ead within the crystal lattice of uraninites caused a hrinkage in the unit cell proportionate with time", nd that this could be used for estimating their ges. In a more recent communication[2] he discussed is method in the light of a classification of uraninites nto three types, namely, the equivalents of artificial O$_2$, and materials having uranium – oxygen ratios f 1 : 2·33 (possibly $U_3O_7$) and 1 : 1·75 (possibly $_4O_7$), respectively, and thinks that they are all haracterized by a fluorite structure with different arameters' in the three cases.

Hoekstra and Katz[3] pointed out that the existence f these oxides in Nature is doubtful. In his answer Vasserstein mentions the occurrence of thorium, tanium and zirconium in some uraninites, and states at "these replacements of uranium are in accordnce with the principle that lower valence of an ement is indicative of larger ionic size, and conersely. The different 'valencies' envisaged in my assification must have influenced the nature of the placements at the time of formation of the minerals".

A number of points made by Dr. Wasserstein in ese communications call for comment.

(1) There is no ground for the supposition that diogenic lead is produced as tetravalent ions. The neration of radium G from radium F actually rings about a superabundance of electrons for tisfying the amount needed in the electronic chitecture of the lead atom.

(2) That the succeeding members of the uranium sintegration series can remain in position in the ystal lattice after the radon stage is reached is tenable, for the following reasons:

(*a*) The radius of the radon atom is 247 per nt that of tetravalent uranium. It is not possible r ions which differ more than 15 per cent in size replace each other.

(*b*) The reaction caused by the emission of the latively heavy α-particle at high speed is certainly g enough to cause a recoil of the parent element rough such a distance that it cannot return to its iginal position.

(*c*) Radon is even larger than the oxygen ion. It nnot diffuse through the uraninite lattice. That actually causes submicroscopic fractures is therere proved by the fact that it is able to leak out of e crystal, as shown by Kulp, Bate and Broecker[4]. It must be pointed out that the lead which is ally generated within these submicroscopic fracres will not be detected by a powder X-ray fraction investigation—it is present as isolated particles, not as a separate crystal, and not in the uraninite lattice.

(3) Even if the generation of lead within the crystal lattice were possible, the resultant shrinkage could not have been proportionate to time, but only to the amount of lead generated within the crystal lattice.

(4) It was not shown how $U_3O_7$ and $U_4O_7$ can exist in the form of a fluorite ($AX_2$) type of structure. How can these small unit cells which Wasserstein proposes contain the number of ions demanded by the formulæ, and Pauling's electrostatic valency principle be satisfied at the same time?

(5) Dr. Wasserstein quotes differential thermal data from a paper by Heystek and Schmidt[5] in support of a γ-type, represented by a sample from Gordonia. This curve actually shows three distinct thermal reactions, and proves that during heating a more complicated process than oxidation of $UO_{1\cdot75}$ to $UO_2$ occurs.

(6) The "principle that lower valence of an element is indicative of larger ionic size, and conversely" does not exist. The following table illustrates examples where the opposite is true.

| Ion | $Sn^{2+}$ | $Sn^{4-}$ | $Pb^{2+}$ | $Pb^{4-}$ | O | $O^{2-}$ | S | $S^{2-}$ |
|---|---|---|---|---|---|---|---|---|
| Valence | 2 | 4 | 2 | 4 | 0 | 2 | 0 | 2 |
| Ionic radius | 0·93 | 2·15 | 1 20 | 2·15 | 0·60 | 1·40 | 1 04 | 1 85 |

Both the magnitude and the sign of the electrostatic charge must be taken into account to correct this statement.

(7) Dr. Wasserstein was able to arrange some of his results in such a way that older samples show smaller unit cell dimensions. This is not surprising, when the following is borne in mind: (*a*) he states that unsuitable material is neglected by means of "sample selection"[3]; (*b*) corrections are applied for the presence of thorium[1]; but the validity of the method by means of which the amount of correction is arrived at was not proved; (*c*) by means of heat treatment in different atmospheres, the unit cell dimensions of unsuitable samples are increased or decreased, and classified into three different groups[3].

(8) He tested his method once for material of unknown age, and found 850 million years for the Witwatersrand uraninite[1]; later isotopic analysis gave an age which differed from this by more than 100 per cent.

S. A. HIEMSTRA

Geological Survey,
P.O. Box 401, Pretoria,
South Africa.

[1] Wasserstein, B., *Nature*, 168, 380 (1951).

[2] Wasserstein, B., *Nature*, 174, 1004 (1954).

[3] Hoekstra, H. R., and Katz, J. J.; Wasserstein, B., *Nature*, 175, 605 (1955).

[4] Kulp, J. L., Bate, G. L., and Broecker, W. S., *Amer. J. Sci.*, 252, 352 (1954).

[5] Heystek, H., and Schmidt, E. R., *Trans. Geol. Soc. S. Afr.*, 56, 165 (1953).

MR. S. A. HIEMSTRA's criticisms can be answered as follows, using his reference numbers.

(1) and (2) The direct evidence that would satisfy him may never be forthcoming; my experimental findings are the available evidence. About four hundred unit cells were measured, and several hundred other X-ray patterns furnished evidence.

The fact that lead demonstrably lowers the parameter of uraninites is evidence that tetravalent lead satisfies the requirements within the lattice in all respects—no other alternative explanation can explain the data as satisfactorily. The ideal mineralogical material from the Belgian Congo provides evidence. Fresh crystals mined at depth are practically free from impurities. Heating in the absence of oxygen does not affect the parameter, clearly indicating that there are no effects due to weathering or radiation damage. The X-ray pattern is that of $UO_2$; but the parameter is less. Only its radiogenic lead-content (about 7 per cent) can be the cause for this reduction in the circumstances. (The reduction in the parameter equals the rate of 0·0035 A. per 100 million years—as has been found for other samples of different ages.)

Mr. Hiemstra suggests here and under (2c) that radiogenic lead occurs outside the lattice. My heating experiments were aimed at detecting such lead or its compounds, as increase of particle size and removal of strain would materially assist in detection by powder X-ray methods. It is very unlikely that such large amounts as 15 per cent—as are found in ancient uraninites—could have escaped detection not only by myself but also by so many chemists.

Radon does not enter the crystal lattice, nor does neutral lead (cf. RaG); but this does not mean that $Pb^{4+}$ is therefore excluded.

I am aware of the (Wigner) recoil effect. X-ray powder diffraction by its very nature records a statistical picture: it seems reasonable to assume that lead ions will drop into vacant U-positions—a process no doubt facilitated by the order effect of heating.

(3) The measured rate of shrinkage seems sufficient comment.

(4) I have previously dealt with $U_4O_7$ or $UO_{1·75}$ [1], and according to Zachariasen this compound has the fluorite structure. I suggested[1] that, as I am in the hands of the chemists for precision of the U : O ratios, this oxide could be written $UO_{2-x}$. In a further communication in *Nature*, July 23, p. 159, I write the chemistry of uraninites as $UO_{2\pm x}$ and such a concept may clear the matter in respect of the smallness of the unit cell.

The following extracts from a letter from Anderson (compare ref. 2) deals with the β-phase, which was proved to have a fluorite structure with a parameter of 5·440 A.; he writes: "A good deal of work was carried out at Harwell after . . . 1949 . . . for various reasons it has not been published . . . the oxidation of $UO_2$ has been proved to take place . . . there are at least three intermediate oxide phases . . . (i) the contracted cubic oxide (called by us β-phase), exactly $UO_{2·25}$ ($U_4O_8$, with 1 additional O atom per unit cell), $a$ = 5·430 kX . . .". This may may be Jolibois's[3] $UO_{2·33}$ or $U_3O_7$; there can be no doubt now that there is a higher oxide of the type $UO_{2+x}$ with a fluorite structure—which is my prototype for the pitchblendes.

(5) Differential thermal analysis requires relatively large samples, and the inclusion of weathered material cannot be avoided; this affected the curve, which nevertheless indicated the essential oxidation—an unpublished curve shows this effect better.

(6) Mr. Hiemstra is guilty of some basic misconceptions in interpreting an elementary principle of crystal chemistry. In dealing with the accepted relationship between valencies and ionic radii, I was, of course, dealing with those of lead and uranium in their role as cations. He has introduced neutral and negative charges; by giving the data incompletely he is highly misleading. If he gives the data on lead more fully, we have:

| | |
|---|---|
| $Pb^{4+}$ | 0·84 A. |
| $Pb^{2+}$ | 1·20 |
| Pb | 1·75 |
| $Pb^{4-}$ | 2·15 |

Basically he believes that "– 4" is bigger th "+ 2"; I stand by my original statement, ". . lower valence of an element is indicative of larg ionic size, and conversely"[1].

(7a) "Sample selection" here means that I selecte the freshest portion in a specimen—there is nothin unusual in doing this. Coupling selection with th minuteness of the sample required for X-ray diffra tion work, I seem to have avoided major effects radon loss—if this is indeed a factor here (cf. Hiemstr 2c)—which is more likely to be linked with weathere material.

(7b) The proof lies in the fact that thorianites hav much higher cube-edges than uraninites, and also the synthesis of the complete series $UO_2$—ThO which has shown that Vegard's law applies. Su data support the validity of my method of correcti for thoria, at least to a first approximation. T corrections used were sometimes small and negligibl

(7c) This is partly answered under (1). In practi all samples are subjected to the same heat trea ments; but owing to their different chemistry, envisaged in my classification, they react differentl If all samples are fresh, then heating in air oxidi the γ-types to give the requisite parameter; tho that could not withstand this treatment are heat in hydrogen instead to give the required paramete Only weathered γ-uraninite enforces a slight mo fication. Types can also be recognized by th origin: γ-uraninite, always with thoria, is typical high-temperature pegmatites; α-uraninite may occ in pegmatites or high-temperature veins, and t pitchblendes occur only in hydrothermal deposi This indicates the heating pattern.

(8) My preliminary result on the Witwatersra uraninites obtained five years ago was at a tim when I did not recognize the true nature of that ty of material. In 1951 I corrected that value in private report which I circulated to many co-worke in which I gave a minimum value of 1,600 milli years—and which, when corrected for thoria, giv more than 1,700 million years: this was a credita effort at a time when no isotope data were availab and my own efforts were of a preliminary nature. was this result that encouraged me to continue work.

One may theorize a great deal about the mecha isms involved (for example, vacant U-positions but I aim mainly at demonstrating that the pa meters of uraninites are affected by both age a the chemistry of the mineral, that is, that there nothing haphazard about the X-ray data; here is neglected but powerful approach to a first-cl riddle.

Since writing the above reply, I have seen a pr print of a chapter by H. R. Hoekstra and J. Ka in a new book[3]; they now accept the presence "a $\beta UO_2$ ($UO_{2·25}$)", and quote confirmatory eviden for Zachariasen's $UO_{1·75}$. Further, Giletti and Ku report radon losses from uraninites to be less th 0·80 per cent.

# FORTHCOMING EVENTS

## Monday, August 29—Friday, September 2

British Pharmaceutical Conference, 1955 (at Aberdeen).

## Wednesday, August 31—Wednesday, September 7

British Association for the Advancement of Science (at istol).—Annual Meeting.

**ednesday, August 31**

At 8.15 p.m.—Sir Robert Robinson, O.M., F.R.S.: "Science and e Scientist" (Presidential Address).

**ursday, September 1**

At 10 a.m.—Sir Alexander Todd, F.R.S.: "Nucleic Acid Structure d Function" (Presidential Address, Section B).
At 10 a.m.—Prof. F. W. Rogers Brambell, F.R.S.: "Immunity d Development" (Presidential Address, Section D).
At 10 a.m.—Dr. S. F. Dorey, F.R.S.: "The Influence of the gineer on Sea Transport and Trade" (Presidential Address, Section ).
At 10 a.m.—Dr. D. B. Harden: "Anthropology: a Scientific ity?" (Presidential Address, Section H).
At 10 a.m.—Prof. K. Mather, F.R.S.: "Biological Organization" residential Address, Section K, K*).
At 11.45 a.m.—Mr. Alec Rodger: "The Effective Use of Man-wer" (Presidential Address, Section J).
At 2.30 p.m.—Mr. P. Ritchie Calder: "The Fragmentation of ience" (Presidential Address, Section X).

**day, September 2**

At 10 a.m.—Prof. N. F. Mott, F.R.S.: "Physics of the Solid State" residential Address, Section A).
At 10 a.m.—Prof. J. R. Hicks: "The Economic Foundation of age Policy" (Presidential Address, Section F).
At 10 a.m.—Prof. E. C. Mobbs: "Afforestation and the Community" hairman's Address, Section K*).
At 10 a.m.—Mr. J. F. Wolfenden: "The Educated Man in 1955" residential Address, Section L).
At 10 a.m.—Mr. W. B. Mercer: "The Impact of Education on arming" (Presidential Address, Section M).
At 11.30 a.m.—Mr. J. N. L. Baker: "Geography and its History" residential Address, Section E).
At 2.30 p.m.—Mr. R. A. Hamilton: "The Scientific Work of the itish North Greenland Expedition" (Special Lecture for Young ople).
At 8 p.m.—Prof. C. F. Powell, F.R.S.: "Experiments at Great ights with Free Balloons".

**urday, September 3**

At 8 p.m.—Prof. David Douglas: "The Living Past".

**nday, September 4**

At 11 a.m.—(In Bristol Cathedral)—Religious Service. Preacher: Rt. Rev. the Lord Bishop of Bristol.
At 8 p.m.—Prof. H. D. F. Kitto: "Scientific and Dramatic Modes Thought".

**nday, September 5**

At 10 a.m.—Mr. W. N. Edwards: "Geographical Distribution of st Floras" (Presidential Address, Section C).
At 10 a.m.—Dr. R. S. Creed: "The Sensory Pathway" (Presidential dress, Section I).
At 8 p.m.—Mr. R. J. C. Atkinson: "Stonehenge in the Light of cent Research".

**esday, September 6**

At 2.30 p.m.—Mr. B. J. Mason: "Man's Influence on the Weather: cent Progress and Future Possibilities" (Special Lecture for Young ople).

---

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or ure the dates mentioned:

Assistant in the Department of Zoology at St. Salvator's College, Andrews—Joint Clerk to the University Court, College Gate, Andrews (August 31).

Assistant Statistician (with a first- or second-class degree in tistics, or in economics combined with statistics), to act as mathe- tical specialist in the Statistics Section—The Secretary, North stern Gas Board, 60 Whitworth Street, Manchester 1 (September 1).

hief Analyst (with a good degree or equivalent qualifications in mistry, and a thorough knowledge of the methods of sampling analysis of coal and mine airs) in the Divisional Scientific partment—The Divisional Chief Scientist, National Coal Board, rthern (N. and C.) Division, The Grange, Grange Avenue, Long- ton, Newcastle-upon-Tyne 1 (September 1).

alytical Chemist (with a degree in chemistry or at least the her national certificate in chemistry) to work mainly on plant terial—The Secretary, National Vegetable Research Station, llesbourne, Warwick (September 3).

ochemist, Basic grade (with a university degree in chemistry biochemistry, or an equivalent qualification)—Prof. C. H. Gray, partment of Chemical Pathology, King's College Hospital, Denmark l, London, S.E.5 (September 3).

Experimental Officer or Assistant Experimental Officer (with a good knowledge of at least two European languages, and preferably with a degree in a scientific subject, or at least a general certificate of education in five subjects, with two scientific subjects at advanced level) in the Colonial Products Laboratory, London, S.W.7, for technical indexing from scientific publications—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting F.591/5A (September 3)

Demonstrator in the Department of Chemistry—The Registrar, King's College, Newcastle-upon-Tyne (September 5).

Assistant Lecturer or Lecturer in Animal Husbandry, in the Faculty of Veterinary Science—The Registrar, The University, Liverpool (September 10).

Physicist (basic grade) for duty in the X-Ray Diagnostic Department—The Administrator and Secretary, University College Hospital, Gower Street, London, W.C.1 (September 10).

Scientific Assistant (university graduate in science or agriculture and preferably with special training in nutrition and/or knowledge of foreign languages), for duties which include abstracting, indexing and proof reading—The Director, Commonwealth Bureau of Animal Nutrition, Rowett Research Institute, Bucksburn, Aberdeenshire (September 10).

Lecturer in Philosophy, and a Lecturer in the Department of Civil and Mechanical Engineering—Joint Clerk to the University Court, Queen's College, Dundee (September 15).

Metallurgist to work in the Bio-mechanical Research Unit in the Faculty of Engineering on the metallurgical problems presented by the use of implants in surgery—The Registrar, University of London, King's College, Strand, London, W.C.2 (September 16).

Lecturer or Assistant Lecturer in Physics—The Registrar, The University, Sheffield (September 17).

Research Officer or Senior Research Officer (with a university honours, or higher degree in science, with research experience in physical chemistry or biochemistry, and experience of the development of new chromatographic methods) in the Division of Plant Industry of the Commonwealth Scientific and Industrial Research Organization, to study the properties of plant proteins with particular reference to their chromatographic separations, to collaborate in the studies of plant protein biosynthesis, and to assist with the development of chromatographic facilities and techniques in the Division—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2 (September 17).

Scientific Officer (with a good honours degree in botany or agricultural botany, and preferably with an interest in fruit culture) in the Department of Pomology, for work on the growth, development and cultivation of the raspberry—The Secretary, Scottish Horticultural Research Institute, Mylnefield, Invergowrie, Dundee (September 17).

Research Worker (with an honours degre in biochemistry or equivalent qualification) to assist in work on the metabolism of the autotrophic nitrifying bacteria—Prof. W. O. Kermack, Department of Biological Chemistry, Marischal College, Aberdeen (September 19).

Lecturer (with a good honours degree in chemical engineering or in physical chemistry) in Mineral Dressing in the Department of Mining—The Registrar, The University, Leeds (September 23).

Research Assistants (2) (with a good honours degree in physics or physical chemistry) in the Department of Mining—The Registrar, The University, Leeds 2 (September 23).

Assistant Lecturer in Dairy Bacteriology—The Registrar, University College of Wales, Aberystwyth (September 30).

Lecturer in Psychology at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, September 30).

May and Baker Research Fellow (graduate in chemistry) to undertake research work on plant growth-regulating substances under the direction of Prof. R. L. Wain—The Registrar, Wye College (University of London), Wye, Kent (September 30).

Senior Lecturer in Anthropology at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, September 30).

Senior Lecturer or Lecturer in Physical Chemistry or Inorganic Chemistry at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 7)

Senior Lecturer and a Junior Lecturer in the Department of Pharmacology and Therapeutics at the University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, October 10).

Chair of Botany at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong, October 15).

Research Fellow (with experience in one of the following subjects: igneous metamorphic or structural petrology; crystallography or crystal physics; physics of high pressure; general geophysics including seismology or rock magnetism) in the Department of Geophysics, Australian National University—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 31).

Senior Lecturer (with an honours degree and a research degree in zoology, and teaching experience at university level) in Zoology at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong, October 31).

Engineer for the design of apparatus producing very strong magnetic fields to be used in low temperature and nuclear research—"Engineer", Clarendon Laboratory, Oxford.

Lecturer (with an honours degree of a British university, and preferably some industrial and/or research experience) in the Physics Department—The Principal, Paisley Technical College, Paisley.

Nuclear Physicist (with at least a good second-class honours degree in physics, and a comprehensive knowledge of high energy physics) in the General Physics Division to lead the work of a research team using a 175 MeV. synchrocyclotron for fundamental studies in the field of high energy physics—The Establishment Officer, United

Kingdom Atomic Energy Authority, Atomic Energy Research Establishment, Harwell, Didcot, Berks, quoting 2/103/363.

Senior Experimental Officer or Experimental Officer (preferably with a degree or equivalent in either physics or chemistry, with experience in the field of emission spectroscopy), for analytical and applied research work on radioactive and non-radioactive materials—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting Ref. A.608/34.

Senior Geneticist, Senior Principal Scientific Officer grade (with at least a second-class honours degree in botany or other natural science, with some years experience of plant breeding and genetics), as Head of the Plant Breeding Division, West African Institute for Oil Palm Research, to plan and execute the research programme of the division, which is directed towards improving the oil-palm by selection and breeding and includes investigation of the genetics and cytology of the crop—The Director of Recruitment, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting BCD.197/199/03.

Senior Reader or Lecturer (preferably with experience in nutrition and food analysis) in Biochemistry—Dean Ernest Said, Queen Aliyah College, Baghdad, Iraq.

Systematic Botanist (with a degree in botany or agricultural botany or equivalent qualification, and preferably with experience of systematic botany or the classification of crop varieties), for work on the classification and identification of varieties of agricultural crops; a Technical Officer (with a degree in agriculture or botany or equivalent qualifications, and preferably with field experience) for Potato Trials; and a Technical Officer (with a degree in botany or equivalent qualifications, and preferably with practical experience of seed production) for Herbage Seed Production—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

Sapir. Pp. ii+199–328. (Philadelphia: American Philosoph
Society, 1955.) 2 dollars.

# THE INTRINSIC VALUE OF SCIENCE

HE title of Sir Robert Robinson's presidential address to the British Association, which is nted in full beginning on p. 433, recalls the ex- ition of the cultural and human value of science ich a former president, Sir Edward Appleton, gave the Association in Liverpool two years ago. The ilarity indeed goes further. Both addresses provoke invite discussion on such topics as the teaching and ining of scientists and the place of science in, and use as, a vehicle of liberal education. But though Robert displays to the full, as did Sir Edward pleton, the place of imagination as well as of alysis and order in the advance of science, his in concern is with the scientist. As Sir Edward tified to the cultural and human value of science, Sir Robert presents the scientist as a human son and displays the conditions under which he s to work, his dignity and his problems, stripped the mystery or magic with which popular opinion ll too prone to invest him, and which in this age of hnology can be so fraught with danger to mankind. Sir Robert expressly excludes scientific method elf from his observations; but there are two ints in connexion with the definition of science th which he starts that are worth emphasizing view of this tendency to attribute mystical magical powers to the scientist. Science, he ists, is simply the record of the system of know- ge and of the conceptions correlating parts of that tem. That record, he points out, may be imperfect d the conceptions erroneous. Accordingly, science potentially fallible, and accordingly also it cannot based on dogma or authority of any kind.

While Sir Robert adds that there are degrees of certainty and that even the apparent revolution in ysics which has occurred in the twentieth century s not so much superseded the older teaching as plemented and extended it by wider generaliza- n, this first point as to the limitations of science of fundamental importance in regard to the ition of the man of science in society. Later in address, in referring to nuclear explosions and confident claim of the physicists that there is no k of unpredictable reactions in the lighter elements uclear tests are taken to further stages, Sir Robert nders whether we really know enough about clear reactions to be sure that there is no loop- e, and whether every conceivable case has been sidered. Cromwell's plea to the General Assembly the Church of Scotland, "I beseech you, by the wels of Christ think it possible you may be mis- ten", might well be emblazoned on the walls of ry research laboratory; and it is the realization ong scientists themselves of the limits of our owledge that has found expression recently in ir misgivings as to the continuance of nuclear test losions and the biological hazards of radiation.

he second point is also well brought out by Sir bert at a later stage in his address. After remarking the improvement of knowledge by successive approximations, he proceeds to illustrate his point by selecting examples from the history of science with the imaginative skill which is the mark of the artist no less than of the creative scientist. It is not, however, so much the way that scientific theory is justified by the success of predictions and by the unanticipated convergence of more than one line of approach that are impressive. Far more important than the fact that the degree of coincidence may become so great as to carry conviction that we have been vouchsafed, if not the whole truth, at least something very closely related to it, is the fact that this whole process depends on freedom of communication. "Who ever", cried Milton in the Areopagitica, "knew Truth to be put to the worse, in a free and open encounter". The principle of free discussion is implicit in the conception of science, and it is the birthright of the scientist.

Probably the most important feature of the Geneva Conference on the Peaceful Uses of Atomic Energy is the demonstration it gave of just that relaxation of secrecy on the scientific aspects of the development of nuclear energy to which Sir Robert refers. The five hundred technical papers read at that Conference discussed details which were close secrets only a short time ago. Now the fruits of some fifteen years of intensive, laborious and costly research are becoming largely international property, with benefits to further advances and advantages in economy of scientific and technical man-power and resources that can scarcely be over-stressed.

Sir Robert Robinson also suggests some form of international consultation before novel and greatly increased releases of energy are attempted. This lay outside the strictly technical orbit of the Geneva Conference; but the very success of the Geneva Conference in discussing matters previously so largely secret led its members to realize that it might soon be necessary for some body—and not a scientific body—to make proper arrangements for administering the solutions to the problems of the nuclear age to which technical advance might point. That in itself is a factor indicating the need for clearer understanding of the scientist and technologist as men, and of the significance of the technical and scientific elements in a political, social or economic problem, on the part of the administrator, whether the latter be Minister or Civil servant.

Meanwhile, however, it is all to the good that the importance of this relaxation of secrecy should be stressed so authoritatively; and scientists generally can show their appreciation of Sir Robert Robinson's address in no more fitting way than by emphasizing at every appropriate opportunity the vital connexion between scientific advance and the free communication and discussion of results and ideas. That this has been so admirably stated on repeated occasions in the past decade—by Sir Henry Dale and by the Commission on Higher Education in the United States, for example—does not minimize the need for continuing this process of educating the public understanding of the prime importance to a free society of academic freedom and untrammelled avenues of communication and discussion. The larger the place science and technology come to occupy in society, the greater the importance to society itself that the scientist should be able to move with freedom toward the truth wherever the path may lead, stayed by no authority or tradition, and hindered by no dogma, prejudice or vested interest from thoroughly exploring every promising avenue he sees. The whole atmosphere of the Geneva Conference warrants the hope that the climate of opinion is changing, and that statesmen and the public generally are disposed to accept an argument that for ten years or more has largely been rejected. To seize that opportunity is not solely a matter for the man of science. Rightly and firmly, Sir Robert includes all branches of knowledge in his definition of science, provided their record has been made without appeal to authority, nor does he believe that any philosophical line of demarcation separates one branch of learning from another.

Here he is at one with J. B. Atkins, who in "Incidents and Reflections" pleaded for the universal recognition that physical science belongs in essence to the humanities, and is a part, and may become the most important part, of that body of teaching, which though once narrowly confined was always destined to expand and in unity embrace the obligations of the good life. Emphatically, too, Sir Robert rejects the assertion that culture is the preserve of students of some particular branches of knowledge and is denied to others. Moreover, while the illustrations he chose to exemplify his thesis show he concurs with Sir Howard Florey's remark, in his Lister Memorial Lecture, that real and continuous progress and understanding in such a field as that of antibiotics research can be obtained only by the collaboration of people with various outlooks and experimental accomplishments, it is clear that Sir Robert recognizes that contributions to scientific advance can come from people whose primary occupation is not usually regarded as scientific.

Sir Robert's skilful exposition of the nature and drama of the scientific discipline may well induce the passing reflexion that a wider and wiser use of the historical method in teaching science might contribute not merely to give the scientist a clearer perspective in his work but also, and perhaps more important still, to give the non-scientist an understanding of the mind and method of the scientist and the conditions necessary for effective scientific work, as well as the limitations of that work. So too in his reference to the universality and the fully international character of science, Sir Robert indicates both the reality of the brotherhood of scientists—which of course is by no means unique—and the real basis for the state of mind which has found expression in Lord Russell's statement and others on the problems of the release of atomic energy. He sees in the world-wide co-operation which the development of science requires, one of the bulwarks of peace.

There are passages in Sir Robert's address whic testify to the intrinsic value of science as fully as d Sir Edward Appleton in his presidential address Liverpool. They recall the view of science whic Eddington advanced in a Gifford Lecture as springi from "a striving which the mind is impelled to follo a questioning that will not be suppressed". But and large, it is in what he reveals of himself in th address, more than in what he said, that Sir Robe displays the human qualities of the man of scien to the world, and the rich contribution he can bri not merely to its material life and technology b also to its thought and experience. The flashi asides, which uncover fresh angles of discussion varied topics, such as the need for a technologic grants committee to administer technological educ tion, the control of nuclear energy developments, the training of scientists, do not distract us from t consciousness that in himself the President exem plifies the judgment, the sense of values and t skilful selection that are the mark of a man of t highest culture. If by culture we mean the abili to think clearly and to express those thoughts language both dignified and lucid, we need look further for evidence that those trained in the physic or biological sciences possess those qualities as ful as any of their fellows, within or without the walls a university.

# CHRISTIAN FAITH IN THE WORLD OF SCIENCE

## Science and Christian Belief

By Prof. C. A. Coulson. (The John Calvin McNe Lectures, 1954.) Pp. x+127. (London: Oxfo University Press, 1955.) 8s. 6d. net.

In these lectures, delivered at the University Chapel Hill, North Carolina, Prof. C. A. Couls has followed up the line of thought set out in h Riddell Lectures in Durham and his address to t British Association at Oxford. He has been singula successful in interpreting the relationship betw the scientific discipline and outlook and that religion and of the Christian faith. In defini religion as "the total response of man to all environment" (p. 83) and by insisting that t scientist is no mere gadget-monger but a ful developed man using not only his curiosity and lo but also his imagination, his reflexion and his pow of commitment, he can present his case that scien represents, as it were, an architect's plan of t building, a plan which gives a true picture of o aspect of the whole but must not claim to be m than this—a plan to be supplemented by ot interpretations and harmonized with them ( 66–68).

Prof. Coulson begins with a searching criticism most of the traditional attempts to relate science religion. His examination of the supposed an thesis, of the attempts to define the intrusions of t one world into the other, of the well-meant desire find room for God in the gaps left by the inco pleteness of the scientific picture, should be studi by every theologian. It is illustrated by a la number of actual examples which show how v ny of the apologists for religion contradict their n professed belief in the omnipresence of God, and at the physical world as external to Him.

In his second lecture he disposes of the idea that ience is merely technology—a particular and ictly limited exercise of the logical intellect. Here ain he brings together a great mass of quotations prove that science, like religion, is a proper activity the whole man, an adventure demanding full use all the faculties and inspired by a belief in the ity and coherence of all reality.

In the third lecture he contends that not only is e whole man involved in the scientific quest but o that this quest is ultimately religious in character d linked with other modes of human response to e universe. It is an essential contribution, not ly to man's understanding of his environment or his control of it, but also to his whole reaction it and experience of it.

Finally, he concludes that this environment is sentially personal or superpersonal in character and at it can therefore be appropriately expressed for manity "in one person, a representative person, an chetype" (p. 112), and that this person is for the ristian the Christ. The scope and significance of is conviction he states briefly, clearly and with levant evidence.

It is difficult for one whose general position is very se to that of this book to express anything but miration for it. If there is to be criticism, it will that the wealth of quotations, though impressive d well chosen, leaves too little room for Prof. ulson's own admirably lucid and effective exposi- ons. It is to be hoped that he will before long give a fuller account of the position here outlined as sees it in regard not only to the present findings science but also to the great issues which to-day nfront mankind.

CHARLES E. RAVEN

## vic University

pects of a British Tradition. By W. H. G. Armytage. . 328+8 plates. (London: Ernest Benn, Ltd., 55.) 30s. net.

THE sub-title of Prof. Armytage's book is "Aspects of a British Tradition", and those rds provide the clue to his design and its fulfil- ent. He begins right back with the earliest impacts Christianity on Britain. In separate chapters he rks through the foundation of universities at ford and Cambridge, the laicization of the pro- sions, the emergence of a scientific spirit, the ntribution of Francis Bacon, the influence of the yal Society, the rise of corporate patronage, and e nineteenth-century "new clerisy". Then, through e conflict of ideas occasioned by the Great Exhibi- n of 1851, we arrive at the efflorescence of civic iversity colleges in England. In the eleventh of e book's fourteen chapters we enter the twentieth ntury, and the last fifty pages give a clear picture the problems which confront the universities of e British Isles to-day.

The main body of the book, then, is historical, not gumentative or theoretical. Each chapter is both essay in itself and a contribution to the developing ry; and each stage in the development of the dition is documented with a wealth of detail. deed, in places the detail becomes so rich that the ordinary reader may be overwhelmed by it, for the accumulation of proper names sometimes clogs the march of the narrative.

Prof. Armytage's general thesis is that the transmission of knowledge demands, in each separate historical context, its own appropriate institutions: that the pushing forward of the frontiers of knowledge is not always best done by institutions suitable for its preservation and transmission; and that the demands of science, pure and applied, require for their satisfaction instruments quite different from the universities of tradition. He sees the modern civic universities, in close alliance with technical and technological colleges and with other research-organizing bodies, as the agents of these vital developments; and his tracing of the historical story is designed to show that this is their destiny.

The fascinating narrative which he unfolds inevitably gives rise to questions. The first is the ancient one, of the nature and definition of 'university' itself. It is not to be expected that the opinions of Walter de Merton, Richard Mulcaster, Cardinal Newman, Abraham Flexner and Bruce Truscot should coincide. But more than once a doubt arises whether Prof. Armytage is not too hospitable to quotations from writers who mean by it simply an institution for higher education whether general, specialized, vocational, scientific or commercial; and this multiplicity of meanings darkens counsel.

A second is whether there really is any genuine historical connexion between scientific and technological studies, on one hand, and, on the other, the kind of institution which we know as 'Redbrick University'. There is no doubt that during their slothful centuries Oxford and Cambridge failed to realize their duties and their opportunities in relation to the new knowledge; and there is no doubt either that within the past hundred years needs which Prof. Armytage cannot avoid calling "banausic" have led to the deliberate inclusion within the modern universities of studies which the more ancient ones found indigestible. But it is difficult to believe that there is a necessary connexion. The older universities are by now scarcely less interested in technology than their younger sisters; and of the population of these latter nearly one half are engaged on arts courses.

A third question concerns the extent to which the newer universities ought to become, or remain, provincial, regional or civic. 'Civic' suggests a relationship with the local civic authorities much more intimate than is customary. 'Regional' suggests a connexion with a particular geographical area, and while this may properly give to a university certain special interests it ought not to determine that university's development. Especially, this local connexion ought not to determine the area of recruitment of its students—'provincial' in that sense is an undesirable adjective. More and more the value of life in a hall of residence is recognized, and although there may be something to be said for concentrating various technological studies in the geographically appropriate places, there is much more to be said for collecting the students from as far afield as may be.

There remain the three most urgent major problems of university policy: the possibility of some genuine marriage inside the university course between the new scientific studies and the wider humanities of tradition; the extent to which the clamant national need for educated technologists is for the universities to supply; and the assessment of the right proportion of university places to the population of the British Isles. Each of these is a matter of daily debate, and to each of them so far the attitude has been empirical, both in the universities and in the nation at large. The growth of the universities during the past fifteen years has been astonishing, not only in the sheer numbers of students and staff, but also in the variety and complexity of the fields of study and investigation. It is natural enough that among its results there should be a certain confusion about aims and untidiness about means. To what extent should the spontaneous and organic development of the individual universities be controlled by some central plan? If at all, how far can central planning avoid infringement of that autonomy which universities have traditionally claimed? Fundamentally, are universities properly regarded as 'community service stations'? These problems Prof. Armytage sets out with clarity and vigour in his concluding chapters.

In fact, this is several books. It is a valuable narrative of the development of many kinds of institution for higher education, including the Inns of Court, the hospitals and the nonconformist academies. It is a series of historical vignettes of particularly fruitful moments in the story of British education. It is a reasoned and well-documented appreciation of the present needs both of the universities and of the society which supports them. Prof. Armytage would not claim that he can prescribe a remedy for our present headaches; but he has certainly given us the material for seeing ourselves in the perspective of a majestically unfolding story.

J. F. WOLFENDEN

## A BIBLIOGRAPHY OF THE WORKS OF LAVOISIER

### A Bibliography of the Works of Antoine Laurent Lavoisier, 1743–1794

By Denis I. Duveen and Herbert S. Klickstein. Pp. xxiii + 493 + 42 plates. (London: Wm. Dawson and Sons, Ltd., and E. Weil, 1954.) £10 10s.

STUDENTS of Lavoisier have hitherto been badly handicapped by the lack of any adequate bibliography of his writings, which cover so many fields in addition to chemistry. Their difficulties were increased since Lavoisier not infrequently did not publish the papers which he had read to the Academy of Sciences in Paris, while the editors of the six volumes of his collected works, the "Œuvres de Lavoisier", had access to his manuscripts and printed them without any indication of whether they had been previously published or not. So there are many traps for the unwary. For example, the account of Lavoisier's earliest scientific investigation, describing his observations of an aurora, was written in 1763 but was not published until 1863.

Mr. Denis Duveen has been an assiduous and discerning collector of everything relating to Lavoisier, and now, with the aid of his unique collection, he and Dr. H. S. Klickstein have given us this comprehensive volume of bibliographical studies, which is the result of years of research and scholarship. Following the modern tradition of 'personalized bibliographies', it contains not only the bibliographical details of all Lavoisier's books and papers and their translations but also a short analysis and appraisal of their contents which will be of th greatest help to students in the future. With th exception of one or two foreign works, copies of a the 705 printed documents catalogued in the bibli graphy are in Mr. Duveen's private collection, pa of which was shown at an exhibition at the Groli Club of New York in 1952.

The bibliography contains six sections dealin respectively, with (1) Lavoisier's papers published i scientific periodicals, (2) his four major works c chemistry, (3) his minor writings which were pul lished separately, (4) his minor contributions to oth works, (5) the reports of the committees of th Academy which were written by him, and ( the various collected editions of his papers ar books.

Lavoisier contributed more than a hundred pape to scientific periodicals, and many of those dealir with his more important chemical discover appeared in the Memoires de l'Academie Royale d Sciences, the volumes of which were usually pul lished several years in arrears. This has cause historians no little difficulty. Papers published b the Academy are listed in the bibliography, not und the years in which the volume containing them w actually published, but under the years which th particular volume covers. This corresponds in mo cases, but not in all, with the date of the reading the paper. A short summary of each paper is giv and a reference to its inclusion in the "Œuvres Lavoisier" which is most useful.

The second section, dealing with his four maj works, the "Opuscules", the "Nomenclature" ar the classic "Traité Elémentaire", contains an inte esting account of the little-known "Memoires Chimie", the fragments of the complete edition his memoirs which Lavoisier had just begun befo he was guillotined. These were never put on sa but distributed privately by Madame Lavoisier 1805.

Sections (3) and (4) contain most of Lavoisier papers on agriculture, political economy and educa tion. Section (5) deals with the reports written b Lavoisier for committees of the Academy appoint to review books submitted for publication with th approval of that august body; and Section (6) wi the various collected editions of his writings, includi most useful details of the contents of the six volum of the "Œuvres" with cross-references to pape already listed in the bibliography and an analysis those which only appeared in the "Œuvres".

It is impossible in a short review to do justice the accuracy of detail and the fine scholarship of th bibliography. Those who have had experience of th difficulty of tracing the exact course of Lavoisie ideas will appreciate the immense amount of stu it has involved, and future historians of chemist will often feel grateful to the authors.

There is one serious omission—a general index, b means of which it would be possible to find imme ately any individual paper or to trace groups papers on particular subjects. There are indexes names, publishers, printers and artists; but the la of a general index does diminish seriously the ava ability of the results of this unique study Lavoisier's writings. It would be quite easy remedy this defect in a short supplementary volum when the opportunity might be taken to include list of the biographies of Lavoisier and the maj papers devoted to the study of his work on the lin of Dr. Holmberg's excellent bibliography of Berzeli

Looking through this book, with its interesting acsimiles of title-pages, one is struck once again with he amazing range of Lavoisier's accomplishment in is short life of fifty years. In chemistry, in physics, 1 physiology, in agriculture, in geology, in education, 1 statistics and in finance he was a pioneer, and in ach his contribution had the modern touch both in hought and phrase. With the publication of his etters in the near future and of his note-books, istorians will have much fresh material, and Mr. uveen and Dr. Klickstein's bibliography will be of nmense value to them in their studies.

HAROLD HARTLEY

# VICTOR VAN STRAELEN

olume Jubilaire—Victor Van Straelen

irecteur de l'Institut royal des Sciences naturelles e Belgique, 1925–1954. Tome 1: Pp. viii+640 (40 lates). Tome 2: Pp. vi+641–1216 (8 plates). Bruxelles: l'Institut royal des Sciences naturelles e Belgique, 1954.) n.p.

PROF. VAN STRAELEN, who was born at Antwerp in 1889, retired in June 1954 from his post s director of the Institut royal des Sciences naturelles e Belgique which he had occupied for twenty-eight ears; at a ceremony of "Manifestation d'Hommage" eld in his honour shortly afterwards he was presented ith two "Volumes Jubilaires" containing contriutions from all his scientific staff.

Prof. Van Straelen has had a most distinguished areer, in the course of which, following the path of s illustrious predecessors, he has guided the study the biological sciences in Belgium and the development of the Institut to a position of world-wide teem and reputation. After a brilliant university areer, followed by service in the Belgian forces uring the First World War, he occupied various ademic posts until at the early age of thirty-five he as appointed director of the Musée royal d'Histoire aturelle de Belgique, which has since become the stitut royal des Sciences naturelles de Belgique.

Van Straelen is primarily a palæontologist, and as particularly distinguished for his researches on e fossil Mollusca and Crustacea; but after this ppointment he devoted his great energies and lministrative abilities to developing the museum d widening its activities, and to encouraging the udy of biology in Belgium. The results of his life's ork are manifest in the Institut. Large though the useum was when he went to it in 1925, it is now eatly increased in size by a range of new and posing buildings which are, however, but a part of e plan that he devised for making the housing of e Institut one of the finest buildings in Europe. is much to be hoped that the plan will be completed before many years have passed. His scientific aff has grown in numbers from five to twenty-seven, d the important collections of the museum have en enormously enriched during his tenure of office. e publications of the Institut have been greatly ultiplied. The well-known *Annales* and the *émoires* have been increased in frequency of pearance and augmented by the addition of a ond series and the publication of many volumes *rs série*; in addition, the publication of the *lletin* was renewed after a lapse of forty-two years. ese are only a few of the many changes wrought by Prof. Van Straelen, who has also been very active in furthering the cause of education in the biological sciences in Belgium.

Prof. Van Straelen is a man of great strength of character who steadfastly refused any form of collaboration during the occupation of his country, and whose eminence has been recognized by the conferment of scientific honours throughout the world. He is a foreign fellow of the Linnean, Zoological and Geological Societies of London, foreign or honorary member of a great number of scientific societies in many other countries, and president of the International Association for the Protection of Nature. In Belgium, among many other scientific activities, he is president of the Institut des Parcs nationaux du Congo Belge, president of the Classe des Sciences of the Académie royale des Sciences, des Lettres et des Beaux-Arts de Belgique, and president of the Association pour l'Étude de la Paléontologie et de la Stratigraphie houillères; he has been responsible for the organization of numerous exploring expeditions to the Belgian territories in Africa.

The articles published in the Victor Van Straelen "Volumes Jubilaires" have been contributed by members of the scientific staff of the Institut royal des Sciences naturelles de Belgique, the Association pour l'Étude de la Paléontologie et de la Stratigraphie houillères, and the Institut des Parcs nationaux du Congo Belge. They represent some of the numerous lines of research that he has encouraged or developed in the course of his career. The volumes are beautifully produced and lavishly illustrated, thanks to the generosity of an anonymous benefactor.

Vol. 1 contains papers on mineralogy, palæobotany and palæozoology. They deal largely with the coal-measures of Belgium and include studies on their flora and fauna. In the section on mineralogy, J. Scheere gives a lengthy lithological study of the rocks of the Upper Westphalian *A* series overlying the coal-measures of the Campine, and R. Van Tassel details the occurrence and characters of the arsenopyrite mineral mispickel in Brabant. In the section on palæobotany, F. Stockmans and Y. Willière summarize their previous studies on the Namurian flora of Belgium, and R. Vanhoorne contributes a short paper on the dating of certain peat deposits by a study of the seeds and pollen recovered from them. In the section on palæozoology, M. Lecompte describes the 'reefs' of pink marble found in the Devonian of the Ardennes and discusses their probable formation by stromatoporids in superficial zones of turbulence and by corals at greater depths; and P. Sartenaer discusses the occurrence of two species of brachiopods from Senzeille and describes one of them as new. A short paper by F. Demanet follows, reporting a re-examination of the schistes of the Anhée coalfield; and in the next paper H. Chaudoir tabulates in detail the stratigraphical distribution of the flora and fauna of the eastern part of the Liège coalfield syncline. A. Pastiels contributes a biometric study of some of the lamellibranchs of the Liège basin, in which a number of species are shown to be divisible into two groups which show little overlap in their dimensions. A long paper by M. Glibert and J. de Heinzelin de Braucourt gives a review of the lower oligocene fauna and flora of Belgium, with illustrations of numerous species of mollusca. The next paper goes farther afield with a study of the lignite-bearing miocene strata and the marine pleistocene beds of eastern Tunisia by W. Van Leckwijck. The volume concludes with papers on the growth of brachiopods of the family Spiriferidae by A. Vandercammen, on some adult fossil Ephemeroptera by G. Demoulin, and an essay on the palaeobiogeography of the Euselachii by E. Casier.

Vol. 2 is devoted to zoology, and more than half of it deals with invertebrates. The first paper is a long essay by E. Leloup on the structure and phylogeny of the siphonophores, in which he concludes that these organisms are derived from littoral gymnoblastic hydrozoa, allied to the Tubulariidae, which have been freed from a sessile benthonic stage through the direct development of the actinula larva. The second is a short contribution by S. Lefevere on the occurrence and significance of esterolytic enzymes in the intestine, and of alkaline phosphatase in the nephridia, of *Nereis diversicolor*. The next two papers are devoted to invertebrates of tropical Africa—the first a study of the Vertiginidae and Valloniidae of Central Africa by W. Adam, and the second a review by A. Capart of the types of the species of fresh-water crabs of the family Potamonidae.

A paper by J. Cooreman gives the results of a two-year ecological study on the hydracarine fauna of a stream in a peat bog in the Hautes Faynes, Belgium; H. Synave discusses African Hemiptera Homoptera and describes a new species of the genus *Cordia*; and A. Collart describes two new species of *Microsania* (Diptera: Platypezidae) from Belgium. G. Fagel makes his twenty-seventh contribution to the study of the staphylinid beetles and describes numerous new species of the genus *Paederus* from the Belgian Congo; and A. Janssens gives his seventeenth contribution to the study of lamellicorn beetles with a description of a new species of *Onthophagus* from the Upemba National Park, to which is added a discussion on the evolution and convergence of certain scarabid beetles.

The first paper on the vertebrates is a revision of the Amphisbaenidae of the Belgian Congo by G. F. de Witte, based on the material in the Musée royal du Congo Belge and the Institut des Parcs nationaux du Congo Belge, many of the specimens having been collected by the author himself. R. Verheyen discusses the migrations of the European population of the ruff and shows that on the northward migration the majority of European ruffs cross the Mediterranean to northern Italy, from which they disperse to their nesting-grounds all over Europe; individual ruffs constantly return to the place of their birth. S. Frechkop discusses the genetic relationships between the anthropoid apes and the other primates. He concludes that it is more satisfactory to substitute for the unconvincing idea of migrations of primates from Africa to the Far East and vice versa, or the unproved idea of hologenesis, the theory of the manifestation of analogous potentialities of evolution (of the same genes) in parallel in Asia and Africa under similar ecological conditions. F. Twiesselmann contributes a long paper on the basic principles of anthropology and stresses the importance of anthropometry in the study of races and populations. P. Jolivet returns to the invertebrates with a study of the evolution of the phytophagous habit in the chrysomelid beetles, and suggests that the passage from primitive polyphagous habits through oligophagy to monophagy has been brought about by a series of restrictive mutations, so that the most striking adaptation produced by selection is the instinctive behaviour that leads to the choice of the food plant.

E. Kesteloot discusses the evolution of the flor and fauna of Flanders and shows that climati changes have caused, and are causing, Atlantic an Mediterranean forms to replace boreal types, an that the coastal belt, which has been greatly change through the past two centuries by afforestation, i the region through which adventitious species, bot of plants and animals, generally become introduced L. Van Meel reports the existence of supersaturation of oxygen in certain natural waters, and suggest that it is produced by the action of ultra-violet light which decomposes the water with the formation o hydrogen peroxide or free oxygen. This radiation i injurious to organisms containing chlorophyll, an the author correlates oxygen supersaturation wit scarcity of phytoplankton.

The final article, by L. Debot, gives an account o the achievements of the Service Éducatif of th Institut royal des Sciences naturelles de Belgiqu during the twenty years since it was set up by Prof Van Straelen.

The first volume contains an excellent photographic portrait of Prof. Van Straelen, and instructiv contrasting aerial views of the Institut as it is to-da and as it was twenty-eight years ago.

These volumes are a fitting tribute to the work o Prof. Van Straelen during more than a quarter of century, and the wide field covered by the numerou articles mentioned above testifies to his man interests and the multifarious branches of the natura sciences which he has taken so active a part i promoting in Belgium. The Institut royal de Sciences naturelles, enlarged out of all recognitio since Prof. Van Straelen became its director, is lasting memorial to his work, and these jubile volumes are the expression of gratitude an esteem from every branch of his staff.

L. Harrison Matthews

# NUCLEAR SPECTROSCOPY

## Beta- and Gamma-Ray Spectroscopy

Edited by Prof. Kai Siegbahn. (Series in Physics. Pp. xxiii+959. (Amsterdam: North-Holland Publishing Company, 1955.) 76 guilders; 152*s.*; 2 dollars.

THE new experimental techniques develope during and since the War have led to a revolution in nuclear spectroscopy. New designs of bet spectrometers give a high precision in energy measurement (one part in two thousand), combined wit excellent resolution. Scintillators provide highl efficient counting devices for gamma rays, so th very weak radiations can be detected. High-spee coincidence circuits facilitate the unravelling complex spectra and the measurements of lifetim of nuclear states down to $10^{-10}$ sec. At the sam time the number of available artificial radioactiv species has increased because of the development nuclear piles, and the larger number of partic accelerators in use.

On the theoretical side, the nuclear shell model an the collective model have provided a basis for th interpretation and classification of complex experimental data. Precise computations of intern conversion coefficients, hand-in-hand with the precise measurement, now make it possible t decide the multipolarity of gamma rays, and so th changes of spin and parity in the nuclear transitio nvolved. A better understanding of the theory of ultipole transitions in nuclei also enables one to btain this information from the lifetimes of nuclear tates. The theory of beta decay has been slower in leveloping and the full nature of the fundamental nteraction is still not known, though it is now fairly ertain that a linear combination of the tensor and calar invariant interactions, with possibly some seudoscalar, is the correct one.

The subject is therefore ripe for a comprehensive urvey. This is what is attempted in the present olume. There are twenty-six chapters by different uthors, dealing with different aspects of beta and amma ray spectroscopy. Some chapters are further ivided into short contributions on related topics by ifferent contributors.

It is inevitable in such a project that there should e some overlap, and it is to the editor's credit that he as kept it down so well, while at the same time overing so much ground. In addition to the techiques of nuclear spectroscopy, which are very lly and usefully covered, the theory of allowed and rbidden transitions, of multipole radiation and ternal conversion, nuclear models, the technique nd theory of angular correlations, the empirical lassification of beta transitions and nuclear isomers, lustrative studies of particular disintegration hemes, there are also sections on such topics as ouble beta decay, positronium, the decay of positrons and the double Compton effect. The study of amma radiation from charged-particle reactions and om neutron capture, both of which give information bout the more highly excited states of nuclei than is sually obtainable from beta radioactivity, are also ach given a chapter.

The book is well printed and well illustrated (though ome of the figures which appear as plates are ollected together away from their proper pages ithout any guide in the text as to their whereabouts). It will be indispensable to any laboratory here any form of nuclear physics is practised, and ndeed in any university library, though its price is kely to restrict its being bought by many dividuals.

A particularly valuable feature is in the numerical ables at the end. They contain the numerical formation needed for almost any evaluation of xperimental data: internal conversion coefficients, ermi functions, X-ray critical absorption energies, ngular correlations, conversion tables from $B\rho$ to nergy in keV., γ-ray absorption coefficients.

The author, and subject, indexes seem to be full nd accurate.

M. H. L. Pryce

# A CHAUCER HOLOGRAPH ?

he Equatorie of the Planetis

dited from Peterhouse MS. 75, I, by Dr. Derek J. rice, with a linguistic analysis by R. M. Wilson. p. xvi+214+14 plates. (Cambridge: At the niversity Press, 1955.) 52*s.* 6*d.* net.

N the course of collecting data for a general history of scientific instruments Dr. Price came across a anuscript in the library of Peterhouse, Cambridge, hich was written in Middle English, was on an tronomical subject, and in which the date 1392 ccurred frequently. He thought that it might be the ising part of Chaucer's "Treatise on the Astrolabe" written in 1391, which was at the time the only instrument tract known to him that was written in Middle English.

The manuscript has been in the library of Peterhouse since 1542 and has been attributed since some date prior to 1542 to Simon Bredon. But he could not have written it since he was dead by 1372, when his will was proved.

The manuscript contains directions for the construction and use of the equatorium (or equatorie, as the manuscript anglicizes the term). This instrument was a planetary calculator, based on the Ptolemaic theory of the motions of the planets, designed to avoid the bulk of the computations involved in deriving planetary positions from the Alfonsine Tables in use at the time. The equatorium, in fact, provides a geometrical construction based on the epicycles and equants of the Ptolemaic theory; to derive the position of a planet at a given time, the mean motus and mean argument are taken from the tables and all else is performed by setting the instrument.

The equatorium, of which there were several different types, was widely used in medieval times; but, in contrast to the astrolabe, few have survived. Only two incomplete examples have been traced; one, in the possession of Merton College, has many features in common with the instrument described in this text. Dr. Price attributes the survival of large numbers of astrolabes to the fact that they could readily be embellished with the art of the metal worker: the equatorium was much more complicated and could not readily escape a purely utilitarian appearance and hence had much less chance of being preserved.

The special interest of this manuscript is that it may be an original work by Chaucer, written by his own hand. The linguistic analysis by Mr. R. M. Wilson shows that it contains many words not recorded elsewhere in Middle English except in the works of Chaucer. There is a reference in it to the "tretis of the astrelabie". The whole of it was written by the same hand, which in its informality is in strong contrast to the formal scribal writing of the period. There are numerous corrections and additions by the same hand. The manuscript may be a translation and adaptation from a Latin original; if so, the original has not survived. There is little doubt that it was written about 1392, probably shortly after the "Treatise on the Astrolabe".

The authenticity of the manuscript as a Chaucer holograph could be established if it could be compared with a genuine specimen of Chaucer's handwriting. Unfortunately there are no certain autograph Chaucer documents known. A document was discovered some few years ago among the Exchequer Bills in the Public Record Office which it is thought may be in Chaucer's hand; it relates to the appointment of a deputy for him, as Comptroller of the Wool Quay in the Port of London, during his absence. On one of the pages of the Equatorie treatise is a note which mentions Chaucer by name; the writing of Chaucer in this note is strikingly similar to the Chaucer in the above-mentioned document, as may be seen from the enlargements given in this volume. Though conclusive proof is lacking that the treatise is a Chaucer holograph, the evidence in its favour is very strong.

In this volume the text is reproduced in facsimile with transliteration opposite, and a translation into modern English is given. The critical commentary includes an analysis of the contents of the manuscrip and of the tables, an account of the Ptolemaic planetary system and of the theory of the equatorium, a history of the equatorium, the linguistic analysis by Mr. R. M. Wilson, and a detailed discussion of the possible ascription to Chaucer. The production of the volume is of the high standard which is characteristic of the Cambridge University Press.

H. SPENCER JONES

# THE PROBLEM OF RACE

## The Colour Problem

A Study of Racial Relations. By Anthony H. Richmond. (Pelican Book No. A. 328.) Pp. 371. (Harmondsworth, Mddx.: Penguin Books, Ltd., 1955.) 3*s*. 6*d*.

## An Essay on Racial Tension

By Philip Mason. Pp. ix+149. (London and New York: Royal Institute of International Affairs, 1954.) 8*s*. 6*d*. net.

THE interest which has recently manifested itself in Great Britain in the problem of race shows signs of becoming steadily more widespread. This is evidenced by the publication of Mr. Richmond's book in the Pelican Series, which will no doubt sell in tens of thousands. The fact that it is also becoming deeper is also to be deduced from Mr. Mason's appointment as director of studies on race relations by the Royal Institute of International Affairs. The books that it has published, however, appear to show that there is not yet a great deal that can be said to an English audience on which remedial action can be based. The present endeavour is to present the facts and remove misconceptions.

Mr. Richmond gives us a comprehensive and scholarly survey, primarily from the historical and political point of view, of the patterns of race relations in South Africa, British Colonial Africa and the British West Indies, and in Great Britain itself, which brings together in a very useful form a large mass of information which would otherwise not be available to the general reader. It is presented cogently, and leads to the conclusion that "so-called 'white civilization' will only be preserved by sharing its fruits with non-Europeans, not by depriving them of its benefits". Mr. Mason's "Essay", on the other hand, is primarily directed towards summarizing the theories and conclusions both of politicians and of scientists, and he seeks to test the validity of their ideas by applying them to the situation in South Africa. The result might have been a work which could be regarded as complementary to Mr. Richmond's; unfortunately, however, Mr. Mason gives an impression that he is 'writing down' to a rather ignorant reader, lacking anything more than a conventional grammar school education, as a target to aim at. Even so, it would have been well if he had demonstrated more clearly that the subject of racial tension is a difficult one to grasp. The recent publications of Unesco show that a great deal of disagreement still exists among physical anthropologists and geneticists on the subject of race, and any glossing-over of this fact necessarily detracts from the value of a work in which the point of view of the scientist is discussed. The concept of race, as applied to human societies, is indeed a very shaky one, and this needs to be made plain.

Mr. Richmond and Mr. Mason agree on one important point, which is that the difficulties that have arisen when representatives of different 'race have been brought into close association with eac other can only be dealt with by a slow process amelioration or reform. "The elimination of pr judice," writes Mr. Richmond, "will almost certain be a long and gradual process." This conclusion echoed in Mr. Mason's statement that "there is quick or easy way to knowledge, and it is only knowledge, and by knowledge based on study, th any firm convictions can be reached. In spite of t urgency, plans for study must be made on the ba that thoroughness must come first and speed second These are the final thoughts of a sociologist and scholar, who share a concern for the welfare of ma kind and an awareness of the rapidity with whi events are now moving. But it must be ask whether these are really the last words that can said on the subject. Social scientists, legislators, a administrators in the United States would probab reply that, given a firm grasp of the objectives th have to be attained, and a determination to atta a substantial proportion of them without delay, mu can be achieved in the immediate future. The succe with which the colour bar has been broken down recent years in the District of Columbia, and t extent to which the educational system of the count is being successfully reorganized on an inter-rac basis as the result of the Supreme Court decisio provide evidence to justify this conclusion. The is much food for thought in this for the Briti citizen.

T. S. SIMEY

# ELECTRIC AND MAGNETIC PROPERTIES OF THIN FILMS

## Conductibilité Électrique des Lames Métalliqu Minces

Par Prof. A. Blanc-Lapierre et Prof. M. Perr (Mémorial des Sciences Physiques—Fascicule 5 Pp. iii+96. (Paris: Gauthier-Villars, 1954.) 11 francs.

## Propriétés Magnétiques des Lames Métalliqu Minces

Par Prof. M. A. Colombani. (Mémorial des Scien Physiques—Fascicule 58.) Pp. iii+78. (Pari Gauthier-Villars, 1954.) 1000 francs.

THESE two small monographs may be regard in a way as similar to the reviews published England in *Progress in Physics*, except that th perhaps assume less knowledge on the reader's pa

Vol. 57 on the electrical properties of very t metallic films is very well written, and the auth take great pains in discussing the advantages a disadvantages of known methods of preparing me films for precise measurement. All interested in way in which the electrical conductivity of thin fil evolves following their preparation, the effects temperature upon the conductivity, the variation conductivity with field strength which is in effect breakdown of Ohm's law, the physical structure such films and the theoretical interpretation of th behaviour, will find much to interest them in t little volume.

Vol. 58, on the magnetic properties of very t films, is also interesting, though one feels t the diagrams might have been produced with same care as in the preceding monograph. Natura ne finds here that much more attention is paid to ilms deposited electrolytically, and it is interesting o note how well Maurain laid the bases of this part f the subject some forty years ago. Since it is found hat in the case of very thin films of ferromagnetic netal the hysteresis cycles are rectangular, it is atural to interpret their behaviour in terms of ingle domain particles, and the relevant theory is dequately discussed in the final pages of the book. s sources for valuable references both little volumes vill be found useful.

# CATALYSIS

**atalysis**

Edited by Paul H. Emmett. Vol. 1: Fundamental rinciples (Part 1). Pp. vi+394. 80s. net. Vol. 2: undamental Principles (Part 2). Pp. vi+473. 96s. et.
New York: Reinhold Publishing Corporation; ondon: Chapman and Hall, Ltd., 1954 and 1955.)

**dvances in Catalysis and Related Subjects**

Edited by W. G. Frankenburg, V. I. Komarewsky nd E. K. Rideal. Vol. 6. Pp. xiii+467. (New ork: Academic Press, Inc.; London: Academic ooks, Ltd., 1954.) 10.50 dollars.

THE present active state of catalysis makes this a very suitable time for the appearance of a new nd comprehensive treatise on this subject, if only s a supplement to somewhat older works such as he "Handbuch der Katalyse" and as a parallel ffort to the current series of monographs included n "Advances in Catalysis".

The general pattern which has been followed is the ow usual and necessary one involving the assembly f a number of articles by individual contributors nder a general editor or editorial panel. Vol. 1 of 'Catalysis" contains eight chapters, most of which give a clearly written account of the present state of nowledge in the field treated. Of these, the chapter y Dr. Emmett on the measurement of the surface rea of solid catalysts will be especially welcomed for ts critical treatment of surface area determinations by he Brunauer–Emmett–Teller and similar methods. n article by H. E. Ries on physical adsorption may e regarded as an introduction to this chapter. The ubsequent series of three sections by K. J. Laidler, n chemisorption, on kinetic laws in surface catalysis, nd on the absolute rates of surface reactions, are ll admirable in their treatment and clarity. This pplies also to the section on magnetism and catalysis y P. W. Selwood; indeed, in view of the importance f paramagnetic characteristics in the theory of the atalytic activity of metals of the eighth group, it ould have been welcome if this chapter had been nger and if it had included recent work on the bserved parallelism between the suppression both f the catalytic activity and of the paramagnetic haracter of these metals by alloying them with iamagnetic metals.

The volume contains two chapters of a type somehat different from the above strictly fundamental reatment of catalytic principles, in that, in these, atalysis is dealt with mainly from an industrial oint of view. Thus, in the section by W. B. Innes on atalyst carriers, promoters, accelerators, poisons and hibitors, a good general description of porous and ther carriers is followed by the tabular presentation of long lists of uncriticized and undiscussed references to patent literature, with the corresponding references to *Chemical Abstracts*. While this extensive use of patent literature might perhaps be justified on grounds of the importance of the industrial uses of catalysis, it is difficult to obtain precise and reliable information from such sources; moreover, in tables of recent literature, some inaccuracies have been noticed, presumably on account of failure to check back to the original papers. The following chapter, on catalyst preparation, by F. G. Ciapetta and C. J. Plank, also has an industrial trend but contains adequate references to journal literature. A minor criticism might perhaps be made with respect to the brevity of the descriptions of the preparation of ordinary catalysts in the text of the article, and to the confinement of detailed preparative directions to a few specialized industrial catalysts.

Vol. 2 is, on the whole, more consistently fundamental in character than Vol. 1. The chapter on theories of heterogeneous catalysis, by H. Eyring and others, contains a comprehensive account of modern views of chemisorptive catalysis, including the thermodynamics and general energetics of chemisorption, and a discussion both of the concept of activated adsorption complexes and of the structure of catalytic surfaces. It must, of course, be borne in mind that, in addition to the chemisorptive type, many reactions are known, both in heterogeneous and in homogeneous catalysis, which obviously operate by cyclic valency changes in the catalyst. The above treatment is amplified by two chapters, both by H. M. Hulburt, on the nature of catalytic surfaces and on that of catalyst–substrate complexes on such surfaces. All these chapters are well planned and, taken together, give a clear review of the theoretical foundations of heterogeneous catalysis. The section on reaction rates and selectivity in catalyst pores, by A. Wheeler, is welcome and timely by reason of the complications which arise by the retention of products within porous catalysts, in that this retention retards the free access of further reactants and, in some cases, modifies the nature of the product.

The structure of some of the sections, particularly in Vol. 1, does not tend to make unnecessary the consultation of original literature. The complete work should, however, become a standard one for inclusion as a matter of course in chemical libraries; and it should be attractive, perhaps specially to industrial chemists, both as a source of technical information and as a synopsis of the theoretical background of catalysis.

"Advances in Catalysis" continues to perform a most useful function by providing, in a convenient form, authoritative and critical summaries of current catalytic theory and practice.

The present volume, which is prefaced by an obituary notice and appreciation of Alwin Mittasch, contains seven further reviews. In the first of these, J. T. Davies discusses catalysis and reaction kinetics at liquid interfaces, with particular reference to the fundamental work of Sir Eric Rideal and others on such reactions. Systems of this nature form an intermediate class between homogeneous catalysis and the far more widely studied case of heterogeneous catalysis at a solid surface; and this review is specially welcome as an emphasis on the increasing importance and interest of reactions, both catalytic and non-catalytic, in the surface film between two liquids. The subsequent monograph, by T. Kwan, of

Hokkaido University, Japan, deals with chemisorption and catalysis. In spite of the greater familiarity of this ground, this section makes stimulating reading and contains evidence of considerable original thought.

A short chapter, by W. P. Dunworth, summarizes recent work on the use of polyvinyl alcohol as a protective colloid for stabilizing finely divided palladium catalysts. This employment of colloids as anti-coagulants dates back to the work of Paal and others at the beginning of the present century; but, unlike the colloids then used (for example, protein degradation products or even natural gums), the newer synthetic plastics now available can be dispersed in non-aqueous liquids. Highly dispersed palladium or similar catalysts, when stabilized in this way, retain their large specific surface and have accordingly a high and stable activity and a low sensitivity to poisoning. P. B. Weisz and C. D. Prater discuss the derivation of catalytic activity constants, of activation energies, and of reaction orders, from measurements carried out with porous catalysts and with special reference to diffusion factors introduced by this porosity. This also is a suggestive article, and includes an attempt to separate the effect of diffusion factors from factors inherent in the true catalytic activity. In a further section, some aspects of acidic and basic catalysis in homogeneous systems are reviewed briefly by M. Kilpatrick. Finally, two modern applications of catalysis in large-scale industry are treated at considerable length in sections on catalytic cracking and on the commercial isomerization of hydrocarbons, written respectively by E. V. Shankland and B. L. Evering.

The volume, taken as a whole, lives up to the high standard of its predecessors. It is, of course, a mixed collection; but the general presentation is good. The editors are to be congratulated on assembling, in the course of the successive volumes, such a representative series of topical reviews, written by authors of many nationalities; but the field of catalysis is very wide and rapidly expanding. The transition of research in catalysis, from a purely empirical approach up to rational planning on the basis of theory and of known regularities, is already well marked. Thus the statement in the obituary notice of Alwin Mittasch that, some fifty years ago, no less than 20,000 different specimens were tested for their activity as catalysts for the synthesis of ammonia, might be contrasted with the certainly far less laborious way in which catalysts for a given reaction can in most cases be selected to-day. This new volume of "Advances in Catalysis" will need no special recommendation on the part of the reviewer.

E. B. MAXTED

## MAN AND ANIMALS

### Animals, Men and Myths

A History of the Influence of Animals on Civilization and Culture. By Morus (Richard Lewinsohn). Pp. 374+31 plates. (London: Victor Gollancz, Ltd., 1954.) 21*s*. net.

THIS is an interesting and readable work which embraces a very extensive field. The author, who uses the pen-name of "Morus", is Dr. Richard Lewinsohn, the head of the Institute of Technical Research in Rio de Janeiro. His book, originally written in German, and now translated into Englis is divided into six parts: (1) Prehistory. Th primitive world. The origin and distribution living forms. The ape-like ancestors of man. ( Domestication and exploitation of animals. Th amenities of the cave dwellers. Animal fable (3) The age of discovery and ideas. Inter-relatio of man and animals. Discovery of new worlds. Th part played by animals in providing the materia for man's clothing. Fabulous animals. (4) Th speculative age. Scientific organization of th animal kingdom. Probability of evolution. The ne southern continent. Experimental zoology. (5) Th age of machines. The Darwinian revolution. Para sitology. Animal intelligence. (6) The age modern chemistry. Genetics. Animal economy an future.

It is obvious that to cover accurately so catholi a syllabus demands from its author encyclopædi knowledge, and from its translator the command an attractive literary style. We congratulate th producers of this book on the possession of thes qualifications, which have enabled them to compile work not, it is true, free from mortal error, bu sufficiently attractive in presentation to guarante that the intelligent reader will be reluctant to put down. The underlying theme is the mutual depend ence of man and animal, which is perhaps over stressed in the statement that "the future existenc or non-existence of animals is in fact more and mor dependent upon the will of man". The illustration are numerous and have been well selected, with few exceptions such as the poor figure on p. 32 after Lewis Carroll, who, great as were his creativ gifts as a writer, was no substitute for John Tenniel as an illustrator. In the translation we must deplore occasional lapses into the figurative language of the boxing ring. For example, the account of the famous meeting of the British Association at Oxford in 1860 is grossly misleading in every particular. The bishop in his manner was eminently suave and restrained. He did not "yell" at Huxley, nor did he "grab a club and smash away". In reply, Huxley did not "land a smasher on the bishop's chin", nor did he describe his attack as "sticking his nose into scientific questions". The present reviewer has not seen the German edition, and hence can only hope that such defects of the English version have no place in the German original.

Among the points requiring attention in a new edition are the following: p. 153, "Avicenna of Cordoba" [*sic*] died in 1037, and was not "one of the most famous doctors of the twelfth century"; p. 189, the term spermatozoa was not introduced by Leeuwenhoek, but by von Baer in 1827; p. 220, Sir Joseph Banks neither discovered nor named the duck-mole. It was discovered by David Collins in 1797, and the first printed description was by G. Shaw in 1799. Collins did not publish his own account until 1802. The Governor of Australia sent two skins of the duck-mole to Banks in 1800, one of which was passed on to Blumenbach, who described and named the species in that year; p. 233, Spallanzani's skilful and delicate regeneration experiments are not aptly described in such language as "he proceeded to slice up a salamander" [? newt] and "tore off" its legs, feet and jaws. Spallanzani's name is incorrectly spelt both in the text and index; p. 272, Darwin did not retire to the Isle of Wight for fourteen months to write the "Origin of Species", nor did he ever write a "thick book on fossil mollusca".

Despite its occasional shortcomings, the book is well worthy of the attention of the uninitiated, who ill derive from it much delightful instruction.

# NATURAL CONTROL OF ANIMAL POPULATIONS

The Distribution and Abundance of Animals
By H. G. Andrewartha and L. C. Birch. Pp. xv+782. Chicago: University of Chicago Press; London: Cambridge University Press, 1954.) 112*s.* 6*d.* net.

THIS large monograph begins by rejecting the relevance of any study of whole animal communities or ecosystems to the understanding of distribution and numbers of animals. It then proceeds to take a firm stand against the general use of mathematical models and, in particular, of ideas connected with biotic relationships and density-dependent processes between populations, as explanations of events in Nature. The authors believe hat the regulation of numbers does not exist in the ense hitherto examined in theoretical and laboratory population ecology. They believe that most fluctuaions consist of the natural recovery of populations each time after minor or major catastrophes, or at any rate changes, which have reduced them, and hat these are usually brought about by weather; hat is, the system of control of numbers in Nature contains only one compensatory process—the innate capacity for increase, pitted against the chaos of outer Nature. This summary of their views is, of course, necessarily a simplification of a tome that contains an extremely large amount of hard intelectual work, valuable case-histories from a number of laboratory and field studies by various people, and a genuine attempt to reduce to logical order the very diffuse field of population ecology (though even here, t is chiefly terrestrial ecology and, within that, the ecology of insects that has provided the main material).

After about fifty pages of preliminary statements, and two chapters on diapause and on dispersal, taking the reader to p. 125, there are two hundred pages about the effects of temperature, moisture and ight, which are interesting in their own right as source material, necessary to the later theory, but not in themselves conclusive as regards the latter. This central section, "Analysis of Environment", continues with about two hundred pages more about biotic relationships such as competition within and between species, predator–prey relationships, food, and so forth. Most of this section about population elationships is written in a highly critical, often polemical, manner, and it forms a sustained and oddly contemptuous attack on what the authors regard as the dogma of the regulation of numbers through varying density-dependent processes based proximately upon biotic links. It does not seem ikely that the reader will be entirely impressed by he implication that nearly all previous research in the subject is irrelevant to the interpretation of field population changes, or that the study of simplified mathematical models and their testing in the laboratory is misleading. There is certainly a real dilemma, recognized by all sensible ecologists, between studying the complexity of naturally interspersed populations with their ecological connexions, subject to variable outer conditions of climate and vegetation (and often the actions of man as a superpower), and the delimitation for study under controlled conditions of parts of this system at a level of precision that will satisfy scientific criteria.

Apart from the last fifty pages, which deal with some genetic matters in ecology, the rest of the book is an attempt to provide a new theory of the control of population density, illustrated by a few examples from the field. The latter include some of the authors' own research upon insects in South Australia. The facts adduced are most interesting, and should be studied dispassionately by ecologists. The trouble one has is that there are as yet practically no field measurements of populations of anything like the refinement possible in the laboratory. For all practical purposes at the present time, we know no more about the behaviour in the field of the innate capacity for increase than Malthus did. The notion of innate capacity for increase, with its stable age distribution, is really quite as highly theoretical and abstract a tool for study as the equation for the logistic curve, or Volterra's predator–prey theories. Apart from the human material originally used, it is so far based entirely upon laboratory work with populations living in supposedly defined conditions. The authors have, indeed, substituted for what they consider a dogma, another just as theoretical and with rather less common sense behind it. In spite of the air of certainty that pervades this large book, there are striking inconsistencies like this. These may not appear obvious at first reading. The style is lucid and the learning great, but the thoughts behind are not always illuminated. It is not clear why so large a part of the book deals with density-dependent processes studied in the laboratory, and yet rejects their application to field events. There are some strange remarks on important topics: for example, that something cannot be a general theory unless it describes a substantial body of empirical facts; that "one would not expect to come across a limiting density in any finite number of observations"; and that only individuals, not populations, can be said to have an environment.

There is, however, so much that is useful and provocative to thought, and it is so sincerely tackled and expounded, that one can forgive the authors a certain amount of word-splitting and special pleading. It is less easy to overlook their evident refusal to understand the way in which scientific thought has to advance in a complex field, by the proper use of abstractions and inductive reasoning. Perhaps it is a good moment for ecologists to try to assess how far our existing knowledge can take us in deciding the relative parts played in the regulation of numbers by self-limitation (though intra-specific competition), other biotic relations, and influences like varying weather, refuges and the like. But I cannot believe that the natural communities of the world will be found to have evolved solely "by guess and by chaos", or that the inter-relations of animal populations have not introduced a gradual order into the structure of animal communities.

The book is well produced, though it could have been half as large and had ten times as many readers; there are, however, some misprints in mathematical formulæ. All research ecologists are recommended to read it in order to try to decide whether, as the dust-cover announces, it provides "a new, satisfying and workman-like theory".

C. S. Elton

# MODERN TRENDS IN CHEMOTHERAPY

By Sir CHARLES HARINGTON, F.R.S.
Director, National Institute for Medical Research

CHEMOTHERAPY, or the treatment of infective diseases by means of drugs, as an empirical method of treatment is no new thing. Two examples that are commonly quoted to illustrate the long history of the chemotherapeutic method are the use of mercury for treatment of syphilis and of quinine for malaria. Chemotherapy as we now understand it, however, is a very different matter; it is a subject for scientific research, requiring for its development the application of many different methods of investigation, and the ever-increasing range of its applications has transformed the treatment of protozoal and bacterial infections in man and animals.

The realization of the potentialities of chemotherapy and the systematic development of the subject have come about during the past fifty years, and they are almost entirely based on the work of Paul Ehrlich, the centenary of whose birth was celebrated in 1954. The present time seems appropriate for a brief review of chemotherapy as it stands to-day and of its probable lines of future progress.

Ehrlich himself had a perfectly clear idea of what he was aiming at in the successful chemotherapeutic drug. He sought compounds which were specifically bound by, and toxic to, infecting organisms, while being relatively harmless to the host; and he was led to believe in the existence of such compounds by his observations on the specific affinity of dyes for certain cells and tissues; his first successful experiments, indeed, were in the treatment of trypanosomal infections of animals with dyestuffs. When these experiments turned out to be without practical significance for the treatment of human infections, Ehrlich turned his attention to other types of chemical compound, and, building on the earlier observation of the trypanocidal action of the organic arsenical compound atoxyl, he was led to his great discovery of the efficacy of arsenical compounds in the treatment of syphilis.

This discovery, with its striking demonstration of the possibility of successful specific treatment of an infective disease by a synthetic drug, was the real starting point of the great effort that has been thrown into chemotherapeutic research. This effort, as was natural, was first mainly concentrated in Germany, where the highly developed chemical industry was inspired by Ehrlich's early successes to devote great resources to the search for new drugs. For a long time there seemed to be little prospect of effective chemotherapy outside the field of protozoal infections; even with this limitation, however, the subject was clearly one of great interest to a country like Great Britain, with large Colonial territories in tropical and sub-tropical regions, and in fact the Medical Research Council has from the outset done all in its power to foster chemotherapeutic research. In recent years this type of research has also become a major interest in the United States, and from that country have come some of the most important discoveries.

Unfortunately, the impetus provided by Ehrlich's discovery, although stimulating a great amount of work, provided no theoretical basis for the systematic development of the subject, and the ensuing attempts to find new drugs remained for long almost entirely empirical. Certain clues were indeed available: one example of successful chemotherapy with a lon history behind it, namely, the use of quinine in th treatment of malaria, has already been mentioned this clue was not, however, directly followed, an the line that was pursued, chiefly by the Germa chemical industry, started rather from the dyestuf among which Ehrlich had observed chemotherapeuti activity in experimental infections. Knowledge o the relationship between chemical structure an biological action was, however, not sufficientl advanced to make this type of approach truly effec tive, and although valuable drugs, such as the anti malarials plasmoquin and mepacrine, resulted fro it, the yield of useful products was discouragingl small in proportion to the expenditure of time an effort.

Even in the early days of chemotherapeuti research, the evidence was available that rea advances could only be made where there was th closest collaboration between chemists and bio logists; the success of the German effort depende not only on the great potential of the Germa chemical industry but also on the importance attache by the pharmaceutical section of this industry t strong biological research departments, an exampl followed in recent years with outstanding success b Imperial Chemical Industries, Ltd., in Britain an by several industrial organizations in the Unite States. Moreover, in Britain we may recall the clos association of Prof. C. H. Browning, of Glasgow with the late Prof. J. B. Cohen, of Leeds, in the development of valuable antiseptics, and with the late Sir Gilbert Morgan and Dr. L. P. Walls in producing the important phenanthridinium series o trypanocidal drugs; we may also recall the long-continued work of Dr. Harold King on chemical constitution and trypanocidal action, which was carried out by him within the biological environment of the National Institute for Medical Research, and the collaboration of Dr. King with the late Prof. Warrington Yorke, of Liverpool, which led to the diamidine drugs, useful in the treatment of kala-azar. These successes may be contrasted with what ca now be seen to have been missed opportunities in researches undertaken by chemists without any definite provision for biological collaboration, or by biologists who were unable to bring their observation to the notice of chemists who might have helped t develop them. Many chemotherapeutic researche have been initiated in departments of organi chemistry, and much work of high quality has been put into these projects with disappointingly little in the way of practically useful results. On the othe hand, already in 1898, in a letter to Carl Weigert, Ehrlich put forward a suggestion which came ver close to the Woods–Fildes theory that will be referred to later; but biochemists were not available to brin his ideas to fruition. Again, penicillin might hav been brought into use at a much earlier date had th potentialities of Sir Alexander Fleming's origina discovery been more fully realized by chemists an biochemists.

In retrospect, it seems that the necessity for close collaboration between chemists and biologists i research on chemotherapy should have been s obvious as to be universally recognized from th utset. That it was not so recognized was due in art to the absence of underlying theory, and to the act that discoveries made by chance or on the basis f slender and even sometimes very dubious reasoning eemed to indicate that the prospects of developing ny comprehensive theory were remote. In these ircumstances, the large-scale, semi-empirical method f screening new synthetic organic compounds ppeared to offer the best chance of success.

Two principal factors have contributed to the very ifferent outlook on chemotherapeutic research that revails to-day. One is the great broadening of the eld of application of chemotherapy that has resulted, rst from Domagk's discovery of the antistreptoccal action of prontosil and the consequent levelopment of the sulphanilamide drugs, and econdly from the discovery of the antibiotics. The ther is the increase in knowledge of the biochemistry f micro-organisms and the realization of the importnce of this subject for the understanding of the node of action of drugs on pathogenic bacteria.

The latter advance is due in large measure to the rork of the Medical Research Council's former Bacterial Chemistry Research Unit under the lirection of Sir Paul Fildes. By patient investigaions over many years, the workers in this Unit had cquired extensive knowledge of the factors important n bacterial growth and metabolism. It was this rork that paved the way for the discovery by D. D. Voods that the sulphanilamide derivatives exercised heir anti-bacterial effect by interference with an ssential bacterial metabolite closely similar in hemical constitution to sulphanilamide itself, namely, -aminobenzoic acid. On the basis of this observation, ir Paul Fildes advanced what was, in fact, the first atisfying theory of chemotherapy; according to his ypothesis, an effective chemotherapeutic agent will e a substance that interferes with some essential netabolic reaction of the pathogenic micro-organism, nd such a substance should be sought among comounds having close chemical similarity with those ormally utilized by the organism in its metabolism. he Woods–Fildes theory is in reality a special pplication of the generalization that emerged from he much earlier work of Prof. J. H. Quastel and his olleagues, in which it was shown that enzymic eactions are inhibited by compounds that are hemically similar to the normal substrates; its evelopment is thus an excellent example of the way which an academic biochemical research can lead an idea of practical importance in medicine.

It is only now that the full value of the Woods–ildes theory is becoming apparent. Early attempts t its application were perhaps too naïve in coneption, and although they produced numerous xamples of interesting biochemical antagonisms, hich clearly fell within the general framework of e theory, they did not lead to the discovery of ractically useful drugs. In recent years, however, reat advances have been made in knowledge of utritional factors that are important or essential for e growth of micro-organisms; with the aid of this nowledge, and with more attention to the practical onsideration that a successful chemotherapeutic gent must attack a metabolic reaction which is more ital to the infecting organism than to the host, we e beginning to see useful results. The most imortant development along these lines that has so r been made is the preparation of synthetic comounds designed to act as antagonists against folic id; substances prepared with this object in view include not only pyrimethamine (one of the more successful antimalarial drugs) but also compounds that preferentially inhibit the growth of neoplastic tissue and thus offer some hope of chemotherapeutic attack on cancer.

In any effective consideration of chemotherapy, it is necessary to avoid too rigid adherence to the original conception of a chemotherapeutic agent as one that is damaging to the parasite and harmless to the host. The parasite is, after all, dependent on the metabolism of the host, and it is at the same time subject to attack by the host's defence mechanisms; one can therefore conceive of the existence of drugs which would arrest the course of an infection, not by direct action on the parasite, but by so altering the metabolism of the host that the parasitic environment becomes unfavourable, or by raising the normal defence mechanism of the host to a higher level of effectiveness.

Recent observations have shown that this conception is of more than theoretical interest. So far as the effect of host metabolism on a parasitic infection is concerned, two examples of the influence of metabolic changes in the host on the malaria parasite are now known. One is the relative resistance of animals on a pure milk diet to malarial infection; this was observed first by Prof. B. G. Maegraith and his colleagues at Liverpool, and further analysis of the observation by F. Hawking and J. D. Fulton in the National Institute for Medical Research has shown that the effect is almost certainly due to the deficiency in milk of certain dietary factors that are essential to the malaria parasite. The second example is given by the interesting suggestion by A. C. Allison that individuals with the sickle-cell trait, whose hæmoglobin is known to be abnormal, are relatively resistant to malarial infection. The first of these observations in particular suggests the possibility of drug treatment that would produce an alteration in metabolism, trivial for the host but disastrous for the parasite.

An example of a chemotherapeutic effect that is apparently exercised at least in part through the host's defence mechanisms is afforded by the action of the anti-filarial drug hetrazan. F. Hawking has shown that hetrazan has no deleterious effect on the microfilariæ in the test-tube, but that treatment with the drug renders them susceptible to very rapid destruction in the body. A more striking instance of chemotherapeutic action exercised through the host emerges from the recent work of P. D'Arcy Hart, R. J. W. Rees and J. W. Cornforth, at the National Institute for Medical Research, on the anti-tuberculous effect of certain high-molecular surface-active compounds (polyoxyethylene ethers of condensation products of substituted phenols with formaldehyde). Here again there is no suggestion of a directly damaging effect of the drug on the tubercle bacillus, but it has been shown by G. B. Mackaness, of the Sir William Dunn Department of Pathology at Oxford, that the monocytes isolated from animals treated with these surface-active agents have acquired the power of inhibiting the growth of tubercle bacilli—a power that is not possessed by monocytes isolated from untreated animals. In this instance, therefore, the natural cellular defences of the body have apparently been artificially reinforced, perhaps by a physical effect of the chemotherapeutic agent.

There is one important section of modern chemotherapeutic research that remains empirical and is likely to continue to do so, namely, the search for new antibiotics; even in the field of antibiotic research, however, there is ample scope for basic biological investigation, particularly of the mode of action of the active compounds. Studies of this nature are important because of the aid they may give in directing synthetic chemical work along profitable lines; moreover, their help is likely to be valuable in the solution of the formidable problem raised by drug resistance, the development of which diminishes or destroys the efficacy of so many otherwise promising chemotherapeutic agents.

It is satisfactory to observe that considerable importance is being attached in Great Britain to the kind of biological research which, as is now clear, must form the basis of further advances in chemotherapy. Apart from researches that have already been mentioned, an example of this is the work of M. R. Pollock and his colleagues, at the National Institute for Medical Research, on adaptive enzyme formation in bacteria and on certain aspects of bacterial genetics; the results of such investigations may be confidently expected to throw light on the nature of the phenomena of drug resistance and drug dependence. A similar remark applies to the study of naturally occurring antagonists to antibiotics; streptomycin, for example, is a drug the use of which readily leads to the development of resistant organisms, and special interest is therefore attached to the quinoline-N-oxides recently shown by J. W. Lightbown and J. W. Cornforth to be streptomycin antagonists produced by *Pseudomonas aeruginosa*. The mode of action of antibiotics, especially in relation to bacterial metabolism, is one of the principal subjects of investigation in the Chemical Microbiology Research Unit of the Medical Research Council, while the work of Prof. H. A. Krebs and his colleagues at Sheffield has provided much of the sort of information about the tissue metabolism of higher animals that we have seen to be necessary for the consideration of chemotherapeutic problems in term of the host as well as of the parasite.

What has been said may suffice to illustrate th way in which biological research has invigorated th whole subject of chemotherapy. From bacterial bio chemistry there is emerging a satisfying theoretica background for the work. In the search for ne synthetic chemotherapeutic drugs, we may expect t be guided in general by this theory and in detail b increasing knowledge of the biochemistry of bacteria metabolism, and by the results of study of the mod of action of naturally occurring antibiotics. Th conception of chemotherapeutic agents has bee widened to include drugs that may exercise thei effects through the host rather than directly on th parasite, and the development of this aspect is bein assisted by investigation of the cellular metabolis of higher animals. Chemotherapy has travelled long way since the days when it amounted to littl more than the empirical selection and biological tes of organic compounds, whether already known o specially prepared for the purpose.

The emphasis that has been laid on the biologica aspects of modern chemotherapeutic research mus not be taken as in any way belittling the contributio that is needed from the organic chemist. The con tribution is indeed greater than ever, because th chemist is needed now not merely to use his intuitio in the supply of new compounds for test, but also a a full and equal scientific partner in a systemati research. The task of the biologist and biochemist i to provide the clues for new advance; the intellectua approach and special skill of the chemist are require in order that these clues should be followed up t advantage. No greater benefit could accrue t chemotherapy than a fuller realization by chemist that modern biological research has converted it int a subject that is worthy of their best endeavour, an is one from which they can expect to gain tru intellectual satisfaction.

---

# POLAR WANDERING

## SOME GEOLOGICAL, DYNAMICAL AND PALAEOMAGNETIC ASPECTS

A COLLOQUIUM on the geological, dynamical and palæomagnetic aspects of polar wandering was held recently by the Department of Geodesy and Geophysics of the University of Cambridge, with Mr. B. C. Browne in the chair. Prof. J. W. Durham (University of California) spoke on the palæontological evidence on continental drift and polar wander, and said that continental drift, in the sense in which it is commonly used, involves a shifting of the continents both with respect to the poles and to one another; either or both of these movements could have occurred. Inasmuch as many proponents of continental drift consider it to have continued well into the Tertiary, it seems that this part of the theory can be adequately tested by comparing the Early Tertiary distribution of marine invertebrates with that now existing, as well as by comparison with fossil faunas the geographical relationships of which are well established.

From Thorson's data[1] on the larval life of marine invertebrates, it is apparent, said Prof. Durham, that a large proportion of a marine fauna in warm temperate or tropical seas could migrate across oceanic depths in an east–west direction for distances up t about nine hundred miles if there was a current simila to the present North Atlantic Gulf Stream; only relatively few species could migrate across muc greater distances. At the present time, out of 48 lamellibranchs and 1,104 gastropods living along th eastern American coast from Florida northwards, 8 lamellibranchs and 94 gastropods have also bee recorded in Europe. Most of these species have a essentially continuous distribution from one area t the other; but 21 of the lamellibranchs and 49 of th gastropods seem to have a discontinuous distributio across the three thousand-odd miles of the Nort Atlantic. Likewise, along the warmer parts of th Pacific shores of the Americas there are 29 species tropical molluscs and echinoids which also occur Polynesia and the Indo-Pacific[2]. From the temperat Pacific coast of North America, more than six species have also been reported as occurring in Japa and, of these, the specific identity of more than ha has been confirmed by comparison of specimen These and other instances indicate that a few mol luscan species are very widespread in modern sea d that the occurrence of similar small numbers of lentical species in widely separated fossil faunas nnot be adduced as proof of continental drift. ikewise, if areas are less than nine hundred miles part and connected by seaways, it would seem that ere should be approximately 50–60 per cent, or ore, of the species in common in similar facies.

By comparison with living faunas, the climatic nd bathymetric aspects of Cenozoic fossil faunas, rovided they are of sufficient size, can be rather curately determined. Examination of Early ertiary marine faunas shows[3] that they were of opical character in the State of Washington and ear New York in North America, in the London nd Paris basins, the Volga basin, north-western ndia, southern Japan, near the Cape in South frica, in south-west Australia, southern New ealand, and in Patagonia, as well as in the present-ay tropics. When the warm temperate faunas that ccur in the Aleutian Peninsula and Kamchatka are lso considered, it is apparent, continued Prof. urham, that the Early Tertiary North Pole must ave been in approximately its present position and ot in the North Pacific as the proponents of drift equire. Eocene faunas of the Gulf Coast of North merica have only two identical, and about nineteen nalogous, species in common with European faunas f similar age. On a percentage basis, this similarity no greater than that present in the living faunas. hen contrasted with the 55 per cent of identical or osely related species occurring in the Indian lower-iddle Oligocene and in north-west Italy—areas hich at this time were connected by the well-ocumented Tethyan seaway and about three ousand miles apart—it is apparent that North merica and Europe were as far apart then as now.

In the older part of the geological record, in so far s it is fossiliferous, it would seem that similar riteria should be used—that entire faunas and not ngle species or special groups of organisms should e considered in evaluating continental drift. For xample, the common occurrence in Brazil and frica, but not elsewhere, of the aquatic reptile *esosaurus* has long been one of the strong argu-ents for the close proximity of the two areas during e Late Palæozoic, for it was supposed to be estricted to a non-marine habitat; yet it has ecently[4] been shown to be associated with marine rganisms in Brazil.

The only marine fauna of the older Mesozoic and alæozoic of Africa and South America which is dequately known and studied[4] is that of the evonian Period. At that time the South African nd Paraná basins had 46 species in common out of 20 species recorded from the Paraná basin and 175 the South African basin. This is a greater number an were common to the Paraná and Bolivian asins, which were contiguous but had a different thological facies. The similarity between the South frican and Paraná basins (38 per cent) is not nough for the two areas to have been nine hundred r less miles apart as they are supposed to have been y the adherents of drift. The similarities are more robably to be explained by similar facies and the resence of an Atlantic island 'stepping stone' such s the Cretaceous Mid-Pacific Mountains[5] of the acific, the tops of which are now 5,000 ft. below ea-level and surrounded by oceanic depths, yet were nce at sea-level. Later Palæozoic and Early Meso-oic faunas are either unknown or too poorly known critical areas for it to be possible to form an estimate of their relationships. However, the late Palæozoic glaciation clearly indicates that there must have been climatic zoning at that time, while the recorded distribution of the fusulinid Foraminifera during the same interval would seem to indicate that the zones were more or less parallel to those now existing.

Summarizing, Prof. Durham stated that Tertiary marine faunas clearly militate against any position of the continents and poles markedly different from that now existing, and the available evidence for the Palæozoic is much more in accord with the present positions than those postulated for continental drift. In the subsequent discussion, Mr. R. A. Couper remarked that it is now known that the spores of the Permian plant *Glossopteris* are wind-distributed. Therefore, the geographical distribution of this plant over several continents could be explained without these having to be contiguous or joined by 'land-bridges'.

Dr. W. J. Arkell (Cambridge) discussed the possibilities and limitations of geology as a control in investigations of the type under consideration. Stratigraphical geology is always striving to break down the 'cinema film' of past periods into its component 'shots', and by means of correlation to obtain separate 'stills' for the whole world at as short intervals as possible. It has to be remembered that this process is still in its early stages. For some years Dr. Arkell has been collecting and sifting all the available information for one single system—the Jurassic—to see how many 'stills' could be obtained, and what sort of picture emerged for the world as a whole for this short stretch of 'film'. It represents approximately twenty-five million years. For correlation purposes, the approach had to be through marine faunas, and primarily based on the group of fossils that gives the best results, namely, the ammonites. Into the stratigraphical framework provided by the ammonites, such as it was, had then to be fitted any other evidence available—from corals, land faunas and floras, lithology, and so on.

After collecting and collating all such evidence, it began to be possible to discern faunal realms and provinces, and then to make deductions about climate in different parts of the Earth. One major mistake often made was to suppose that one such pattern of realms and provinces persisted throughout the whole Jurassic period. Actually, the frontiers were continually changing, and the patterns at the beginning and end of the Jurassic were completely different. How much such changes were due to climatic changes and how much to alterations in the distribution of land and sea it is very difficult to say: in any event, the two factors may have interacted considerably, major geographical changes producing climatic changes over large areas and even, possibly, the whole Earth.

One fact which stands out as of special importance in connexion with the present discussion is that at all times in the Jurassic (and Cretaceous) there was a rich and varied ammonite fauna in the Arctic Ocean. From its occurrence on all the lands at present bordering that ocean—in northern Siberia, Franz Josef Land, Spitsbergen, north-eastern Greenland and the Canadian Arctic—and its identity at any given moment in all those places, it is obvious that this fauna lived and bred in the Arctic Ocean, which therefore cannot have had an ice cap as at present.

In the Lower Jurassic the Arctic Ocean molluscan fauna is no different from that found in all the other oceans of the world. There is one universal faunal realm. That the temperature was much more even than at present is proved also by the existence of rich flora in north-eastern Greenland and Grahamland, and by the fact that these floras scarcely differs from those found in Yorkshire and Sardinia.

Dr. Arkell is of the opinion that during the Middle Jurassic the uplift of land all around the Arctic Circle cut off the Arctic Ocean as a completely closed Mediterranean-type sea. At least, when the next transgressions began at the end of the Middle Jurassic and in the Upper Jurassic, a complete differentiated boreal fauna appeared for the first time and spread southward from the Arctic over the surrounding continental margins. Distribution maps show clearly that this fauna originated in the Arctic Ocean and continued to be centred there for the rest of the Jurassic, becoming progressively more differentiated, but sometimes retreating before, or mingling with, temporary advances of the equatorial faunas.

So it is obvious that throughout the Jurassic the Arctic Ocean, which is at present almost fully covered by permanent ice, was the breeding ground of a rich marine molluscan fauna secreting large calcareous shells, and in no wise more stunted or impoverished than their relatives in lower latitudes. In any event, no glacial deposits of any kind are known in the Jurassic. There are two possible explanations of this. Either the general temperature of the Earth was higher even than at present and, in particular, the polar regions were warmer, or the poles were in some other position. There is only one position where the poles could possibly have been in the Jurassic if they have to be assumed to be as cold as now: namely, the North Pole in the North Pacific and the South Pole in the South Atlantic. But even then, to get the North Pole sufficiently far south of rich Jurassic faunas in Japan and southern Alaska brings the equator too far north on the European side. The most likely position for the Jurassic equator is through southern Europe, following a belt of luxuriant coral reefs and sponge reefs. However, it is not possible to deny that the North Pole could have lain in the North Pacific during the Jurassic, because this is a region about which our knowledge is a complete blank, as is the corresponding position for the South Pole, in the middle of the South Atlantic. Moreover, it seems that if the poles were in those positions, it is quite likely that ocean currents would prevent ice caps forming, and that this would have a profound effect on world climates.

There is some evidence that the Arctic has been cooler than other oceans, as is shown by the scarcity of limestones and the absence of corals. If these facts are rightly interpreted, they suggest that the North Pole has been about where it is at present, but that the climate of the whole Earth was warmer and more even. We are then led to seek for a cosmic explanation, such as fluctuations in the amount of radiation received from the Sun.

Mr. T. Gold (Royal Greenwich Observatory) discussed the dynamics of the problem of polar wandering[6]. A movement of the entire Earth relative to the poles of rotation can be achieved by internal effects; only the vector of angular momentum has to remain fixed in space. If we have a stationary sphere resembling the Earth, a beetle weighing one gram could turn it over once by walking $10^{27}$ times around it. If instead we have a rotating sphere, then the beetle can cause any desired angle of movement of the poles relative to the sphere by merely sitting in th right place.

The actual Earth possesses greater stability tha this by virtue of its shape. It is spinning around principal axis of inertia of greater moment than th other two, and any departure from this conditio implies an increase of energy, if the angular momen tum is to remain the same. If the Earth were perfectly rigid body, then no processes that we coul suppose to have occurred could have caused a sig nificant amount of polar wander. But, as it is onl the stiffness of the spheroidal shape that gives such stability, then, should there be no such stiffnes over long periods, there would also be no stability . Earthquake waves and tidal deformations, bein effects that are very fast compared with the slo creep that is required to allow polar wander, canno therefore, be invoked. However, there exists motion with a period of a little more than a yea which has just the required effect of distorting th Earth as a whole, and thereby moving the axis symmetry of the spheroid. This is the so-called 'fre or 'Eulerian' nutation, whereby the axis of rotatio moves by a small angle, of the order of ¼″ relativ to the Earth, with a period of about 14 month Any plastic flow of the body of the Earth in suc periods, in response to the forces resulting fron this slightly misaligned spin, would show itself in damping of the motion. In fact, the motion i heavily damped, such that it would decay, in th absence of disturbances, to $1/e$ in ten periods or les But this damping can also be attributed to othe causes. The fluid core of the Earth has been though to be a source of the damping, but Prof. H. Bond and Mr. Gold have shown that it is too small[7]. I the mantle, where the dissipative action must there fore take place, one can attribute it to certain type of non-elastic behaviour which do not result i permanent deformations. On the other hand, as th shape of the Earth is just the one appropriate to it present speed of rotation, this requires an explanatio in terms of plastic flow. Also, plastic flow is th most common non-elastic behaviour of solids whe they are heated to a temperature not far from thei melting point. If, then, one attributes the dampin to plastic flow, one knows the approximate magnitud of the effect. Here lies the problem: What effec would this amount of plasticity have so far as pola wander is concerned?

If we knew the nature and magnitude of a dis turbance, such as a redistribution of mass on th surface, then we could calculate the rate and exten of polar wander which it would cause. A redistri bution of mass would have the immediate effect o forcing the Earth to spin around a slightly displace axis. The plasticity suggested by the free nutation i such as to cause the figure to be distorted in a directio whereby the shape will approximate to one appro priate to the new axis of rotation, at a rate of abou 10 per cent per year. This is then responsible for secular effect, for the axis of figure cannot b coincident with the axis of rotation unless it happen to be also a principal axis of inertia; a movemen through a large angle might be required to achiev such a coincidence. The rate of the movement i relation to tectonic events can be illustrated a follows: if a continent the size of South Americ were raised by three metres, then it would take abou a million years for the axes to swing around by a angle of the order of 90° to the new position o secular stability.

A movement of the poles on the Earth causes a rtain amount of redistribution of mass in turn. he largest effect is the change in polar glaciation, ıd so in sea-level, and this can work in a sense ther to help or to hinder polar wander. The most teresting effect would be connected with a hindrance, amely, the occurrence of a 'pole trap' where the iduced changes of mass would counteract other isturbances and hold the axis until either a ifficiently large change occurred elsewhere, or until e distribution of land and water in the polar zone ving rise to the pole trap was substantially altered. any such mechanism has been at work, then we ust expect the polar wander during geological time have occurred in a series of jerks rather than as a eady movement.

Mr. J. Parry asked whether the present small drift the Pole could be attributed to any known dynamal processes, and Mr. Gold replied that the rate of elting of the Greenland ice gives an effect which is the correct order of magnitude within the uncer-inties of the data available. In answer to a question y Mr. B. C. Browne, Mr. Gold stated that conti-ental drift would certainly imply the occurrence of olar wander, since, for the continents to slither ound, so great a degree of plasticity is required at polar wander can take place very easily; polar ander, however, does not conversely imply conti-ental drifting, because movement of the poles could cur in a much more rigid earth.

Dr. S. K. Runcorn (Cambridge) described the ferences which have been drawn from the direction magnetization of those rocks the magnetic stability which can be established with some degree of nfidence. The fundamental hypothesis is that the arth's magnetic field, averaged over a period of veral thousand years, corresponds to that of an ial geocentric dipole. Thus it is necessary to sample om a sufficiently long stratigraphical sequence in der to eliminate the effects of secular variation and ndom errors. The hypothesis seems reasonable hen the control exerted by the Coriolis force on the otions in the Earth's core is taken into con-deration[9]. The palæomagnetism of Tertiary lava ows verifies the hypothesis for the Earth's more cent history[9], and the situation is unlikely to have een substantially different at any earlier time.

The palæomagnetic evidence that the polarity of the omagnetic field has often been reversed many times ithin a geological period, without an alteration in e direction of the field, is further evidence that the is of the field is fixed in the Earth in a fundamental ay. Its coincidence with the axis of rotation therere seems natural[9]. The palæomagnetic record prior Tertiary times is fragmentary; but it is clear that, part from reversals of polarity of the field, its mean rection has changed slowly through geological time. he simplest interpretation of this is to assume a andering of the pole of rotation of the Earth rrying the mean magnetic pole with it. From the sults of a palæomagnetic survey of sedimentary rata and lava flows undertaken by the Department Geodesy and Geophysics at Cambridge, the motion the Pole throughout the past six hundred million ears has been traced in outline[10]. The examination the palæomagnetism of rocks in other continents as not proceeded so far as in Britain, but the avail-le data, shown in Table 1, are in approximate greement with the British results.

Dr. Runcorn next considered an explanation of the asonably steady movement of the pole of rotation from the mid-Pacific to its present position. The mechanism is required to have a correspondingly long time-scale. A lack of symmetry in convection currents in the Earth's mantle seems a possible cause; effects within the fluid core are unlikely to persist in the one direction long enough. It is probable that the equatorial bulge of the Earth adjusts itself to any new axis of rotation in a time very short compared with geological time. Thus, in discussing the dynamics of the problem, it is necessary simply to take axes fixed in the spheroidal earth and then to consider how much angular momentum needs to be generated in a certain part of the mantle to cause the remainder of the Earth to rotate through about 90° since later Pre-Cambrian times. A meridional convection current below the non-Pacific hemisphere rising to the south and falling to the north may be postulated, or one of opposite sense beneath the Pacific hemisphere, or several cells of differing intensities. The number of rotations made by such currents since Pre-Cambrian times depends largely on the amount of matter in motion, but has to be more than about fifteen. This corresponds to convective velocities of greater than 2 cm./year. In an earth of exactly spherically symmetrical properties, such a convection system could not occur. The persistent absence or comparative weakness of convection systems in part of the mantle since the Pre-Cambrian may, however, have also caused the present contrast between the largely continental nature of one hemisphere and the oceanic nature of the other, by affecting the extent to which the acidic rocks differentiated.

Mr. Gold commented that the effects he had described earlier depend on the basic fact that the Earth is rotating. The instantaneous effect of such a process as convection in the mantle is very much smaller than that of the process he had described.

Table 1. APPROXIMATE POSITIONS OF THE MAGNETIC NORTH POLE DURING GEOLOGICAL TIME
(Summarized from various sources, refs. 8–14)

| Geological period | Great Britain | North America | Other Continents |
|---|---|---|---|

| Late Pre-Cambrian | 5° S., 131° W. (Upper Torridonian, north-western Scotland, ref. 11) | 30° N., 148° W. (Hakatai Shales, Arizona†)<br>45° N., 90° W (Diabase dykes, Michigan, ref. 13) | |
| Earlier Pre-Cambrian | 37° N., 109° W. (Diabaig Group, Torridonian, north-western Scotland, ref. 11) | | |

* Mean based on such a small number of extrusive rocks that it is doubtful whether the effect due to secular variation is eliminated.
** Mean based on a single flow.
† Runcorn, S. K. (unpublished).
‡ Gough, D. L (unpublished).

If the Earth were taken to be stationary, the convection currents would cause a slow rotation in the same manner as the beetle crawling around the surface. Prof. O. T. Jones welcomed the results of the palæomagnetic surveys. He stated that, from his recent studies of the red sandstones in the Devonian and Triassic, he had concluded that they have been derived from the erosion of tropical soils. This suggests that the equator, during the two periods, has lain near the British Isles—a conclusion which is in agreement with the implications of Dr. Runcorn's palæomagnetic data.

# A FURTHER FRAGMENT OF THE SWANSCOMBE SKULL

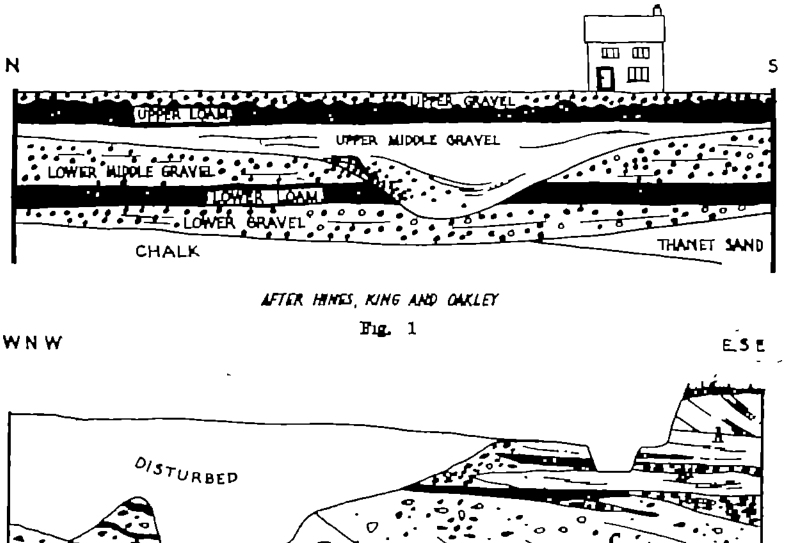
By J. WYMER

THE right parietal of a human skull, found in the Middle Gravels at Swanscombe, Kent, on July 30 of this year, was discovered during excavations under licence from the Nature Conservancy (see *Nature*, Aug. 13, p. 287; for "Mr. Adrian Jones" read "Mr. Adrian Gibson"): a section was to be cleared from near the top of the Upper Middle Gravel, through the Lower Middle Gravel to the Lower Loam, for the purpose of studying the deposits and their archæological content. The spot chosen was close to the site of Mr. A. T. Marston's discoveries of 1935 and 1936, when he found the occipital and left parietal of Swanscombe Man. It is one of the few places in the reserve where undisturbed Middle Gravel deposits exist, although the are almost completely buried beneath dump an scree. Previous work in the pit for five years ha proved the existence of this remaining piece.

The geology of the Swanscombe deposits is we known, having been carefully studied during th years of commercial excavation, when large exposure rendered the task more practical. Now there ar only a few small patches where any of the undisturbe deposits can be seen. All these terrace deposits except perhaps the topmost solifluxion layer, are o great interglacial age, possibly 250,000 years old, an they fill a large channel cut in th solid Thanet Sand and Chalk almost a mile wide. When th River Thames flowed at this level it meandered across its flood plain scouring out new channels an filling in old. Such a channe remains 'fossilized' in the Middl Gravels of Swanscombe, the Uppe Middle Gravel representing a channel cut into the Lower Middl Gravel and afterwards filled wit gravels and sand. It was nea the base of this channel, not fa from its banks, that the Swanscombe Man fragments were found in association with mammalia remains and flint artifacts databl to the middle period of the Acheulian flint industry. The complet section is illustrated diagrammatically in Fig. 1.

The channel of Upper Middl Gravel is obviously more recen than the Lower Middle Gravel below; but they both contain flint industry of Middle Acheulia type. Some authorities consider th Upper Middle Gravel flint industr to be more evolved; but this i debatable. The surface level i 110 ft., and the bottom of th main channel attains a depth c 40 ft.

A thick capping of overburde and the lack of an existing fac made it necessary for the excavatio



AFTER HINES, KING AND OAKLEY

Fig. 1

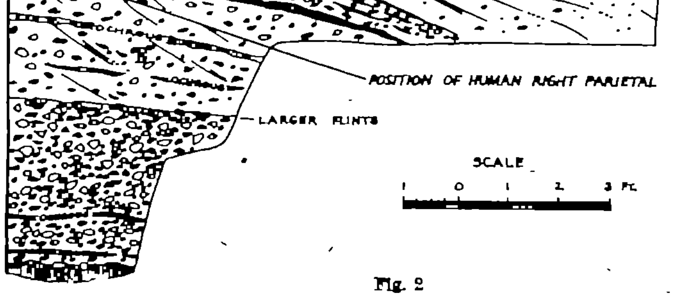


Fig. 2

be conducted downwards by horizontal planes in rder to determine the lay of the strata. The current-edded sand at the top of the excavation was recog-zed as part of the Upper Middle. It was devoid of one or flint artifacts; but a thin seam of gravel mning through it (*A*1 in Fig. 2) yielded numerous nt flakes, as did the thicker seam of gravel below 3), which also contained a small hand-axe, two iniature cores and some bone fragments, as yet nidentified. The very loose sand with stones beneath ntained few artifacts and no bone. Layers *A*1 and were approximately horizontal in a west-north-est–east-south-east direction, but at right angles lowed a slight dip to the south-south-west.

On the second day of the excavation, in the west-orth-west end of the section, a thin band of very hrous gravel was revealed with unstained gravel eneath it. This had a steep dip to the east-south-ast and south-south-west. Immediately, several one fragments and flint flakes were found. Further moval of material showed more inconsistent bands, lso dipping but tending to converge upon the east-outh-east. The gravel continued to be very rich in int artifacts and bone fragments; many of the int flakes were lustreless and sharp, as if freshly truck, others were slightly rolled. Excavation in his region was very difficult because of the proximity f thick, loose overlay, which tended to fall. A hicker band of dark, stained gravel was exposed eneath, and as this was being examined a small iece of bone showed through the lighter gravel at s base. The surrounding material was cleared away y the fingers and the new find, a right parietal, was xposed *in situ*, dome upwards. Its upper surface, t least, was seen to be in soft, soapy condition, and ncient cracks already existed. It was decided to ease all further work in order to decrease the prob-bility of a fall of the disturbed material upon it, ut to leave the bone *in situ*. Photographs were aken and a temporary protection of boards placed ver the parietal in case of a dangerous fall; Mr. Iarston arrived two hours later and confirmed the iscovery. A protective covering of plaster was made ver the bone; but the loose nature of the gravel nd the existing cracks defied attempts to extricate he fragment complete. All the pieces, however, rere retrieved without damage to them and packed arefully in a box that was not opened again until rrival at the British Museum (Natural History) on ugust 2, save for the placing of a saturated wad of otton-wool above to prevent any serious drying out.

Fig. 2 shows the conclusion of the excavation with he Lower Gravel (*F*) exposed, resting upon the enacious Lower Loam (*G*).

Mr. Marston confirmed that his occipital bone was found 51 ft. to the west-north-west of the new find and 49 ft. from the left parietal, the position of the three fragments forming a triangle with sides 51, 49 and 24 ft. In his report on the discoveries (*J. Roy. Anthrop. Soc.*, 67, 350; 1937), his geological section agrees exactly with the new one figured, showing four oblique ochrous layers and, of great significance, the bottom one as the bone layer. The new fragment was barely one inch below this seam in the unstained sandy gravel, a difference of no importance in a river deposit. The only item of interpretation in which the new section differs from Mr. Marston's is that the layer of larger flints at the top of the gravel marked *F* is considered to be the junction of the Lower and Upper Middle Gravels. Mr. Marston features the large flints but accepts the bottom ochrous band (the bone layer) as the junction. The gravel of *F* is more compact and darker than that of the looser, lighter gravel above it (*E*), which contained bone fragments. No bone fragments were found in *F*.

A comparison of the two sections shows that there can be no doubt that the new right parietal was found in the same stratum as that in which Mr. Marston found an occipital and left parietal in 1935–36. This renders the fact that all three fragments fit each other perfectly, belonging to the skull of the same individual, a little less remark-able.

Numerous bone fragments were found in associa-tion with the right parietal, and these are now at the British Museum for purposes of hardening and identification. It is hoped that they may add to the list of fauna from this level. Almost three hundred primary and finishing flint flakes were found during the excavation, of which only twelve showed signs of possible utilization. Four small, primitive hand-axes were also found, typical of the Acheulian flint industry as represented at Swanscombe, as well as the point of a larger, finely finished hand-axe and a magnificent flake 'knife'. A full account of these artifacts will appear in the forthcoming report. Most of them were in a very sharp condition, with only a few minute chippings along the edge and a lustre from rolling in the water. Many, however, are lustre-less and virtually in mint condition. Although separated, the skull fragments show very little abrasion from rolling and there can be no doubt that the flint industry is contemporary.

Inside the triangle formed by the position of the three skull fragments recovered remains a mound, part of which is definitely undisturbed gravel of the skull zone. This area is now efficiently protected, and is to be excavated in the near future.

---

# USE OF RADIOACTIVE MATERIALS IN BIOLOGICAL ASSAY

A JOINT meeting of the Society for Analytical Chemistry, the Royal Institute of Chemistry, he Society of Chemical Industry and the Chemical ociety was held during July 11 and 12 in the Bio-hemistry Department of the University of Edin-urgh; the purpose of the meeting was a symposium n "The Use of Radioactive Materials in Biological ssay". Nine papers were read by invited speakers, nd the programme also included a dinner and a isit to the Institute of Seaweed Research.

Public attention now being focused on the peaceful ses of atomic energy and its by-products, it was perhaps not inappropriate that members of four learned societies should meet for the purpose of dis-cussing some of the latest applications of the isotope technique to biological problems. Some speakers, however, had obviously found difficulty in fitting the subject of their paper to the rather narrow field where biological assay and the applications of radio-active isotopes overlap. That the meeting was a success was in the main due to their interpreting the title of the symposium somewhat widely.

After a brief introductory address by Prof. G. F. Marrian, in which he recalled the pioneer work done in the field of radioactive tracers by G. von Hevesy and his collaborators, the present writer gave an introductory paper on the determination of radioactive isotopes in biological samples. For the benefit of those not familiar with the instruments available for this purpose the first part of the paper was elementary in character, and was followed by an account of the more refined technique of gas-counting, by means of which the isotopes of carbon and hydrogen can be determined with high precision when present together in the same sample. A lively discussion followed, and most members present showed that they had an intimate knowledge not only of the virtues but more particularly the vices of many of the types of counter available. During the discussion on gas counting, Mr. F. P. W. Wintringham pointed out that ionization chambers used in conjunction with the most recent types of d.c. amplifiers are ultimately more sensitive than counters, but that they probably require more skill to operate and are not suited for use by assistant staff.

Dr. E. Lester Smith, of Glaxo Laboratories, Ltd., followed with a paper on the principles of isotope dilution assays. He exemplified the use of this valuable technique by means of an imaginary application to the determination of sodium chloride in sea water, and then enumerated the essential criteria for successful application of the technique. The most important of these is the isolation of a pure sample of the compound to be determined, once mixing with the labelled material is complete. This is sometimes very difficult, recrystallization to constant specific activity being often a laborious procedure. A useful application to the vitamin $B_{12}$ field is the determination of the vitamin in crude fermentation liquors. These contain too many interfering substances for colorimetric or microbiological methods to be easily applied, but the problem has been solved by the use of vitamin $B_{12}$ labelled with cobalt-60. A known amount of known specific activity is added to the fermentation liquors, and a pure sample of the $B_{12}$ is isolated using resin-column chromatography. Ultimately the purified vitamin $B_{12}$ is counted in a liquid counter. The chief disadvantage of the method is the four-step purification procedure. In the course of his paper, Dr. Lester Smith also referred to more sophisticated applications of the technique, mentioning in this connexion the use of labelled reagents, for example, iodopiperonyl chloride labelled with iodine-131 for the determination of amino-acids in protein hydrolysates. He also referred to the reversed isotope dilution technique, in which the total amount of a labelled constituent of a mixture is determined by adding a known weight of unlabelled substance, re-isolating it and determining its specific activity. From this and from the weight added, the total activity of the substance in the mixture can be calculated. This is sometimes referred to as the carrier technique, and as such was more familiar to some members of the audience.

Another practical application of the technique to what might be termed a commercial problem was described by Mr. G. C. Ashton, also of Glaxo Laboratories. This problem is the determination of penicillin G (benzylpenicillin) in fermentation liquors. These contain also other penicillins and other antibiotics which virtually rule out microbiological assay. Methods are available in the literature for the preparation of deuterium- or $^{14}$C-labelled penicillin G suitable for isotope dilution applications; but the deuterium-labelled penicillin in particular is too costly and laborious to produce with a sufficiently hig isotopic abundance for practical applications. (Thi consideration does not, of course, apply to tritium which is not only cheaper than deuterium but als cheaper than carbon-14.) In the method described the $^{14}$C-labelled material is prepared by standard procedures. Known activities are added to the fermentation liquors and penicillin G isolated and its specifi activity determined. It was in the accuracy claime for his radioassays that Mr. Ashton provoked mos discussion, his claims for closer than 5 per cent agreements between replicates being questioned by som speakers. His assertion that the counting rate o thick samples continues to increase beyond th usually accepted infinite thickness value was confirmed by Dr. W. F. Pover, of Birmingham, and wa attributed to edge effects.

Dr. A. S. McFarlane, of the National Institute fo Medical Research, Mill Hill, gave an account of th preparation and research applications of radioiodinated plasma proteins. It has been found tha if the protein molecules contain not more than ten atoms of iodine per molecule, they are unchanged antigenically. More than ten atoms iodine pe molecule produces an antigenically different protein with different crystalline properties. When radioiodine is used, it is not sufficient to have an *averag* of less than ten atoms iodine per protein molecule steps must be taken to see that no appreciable proportion of the molecules contains more iodine than this because, having different chemical properties and, in consequence of the high iodine content a relatively high specific activity, their presence wil give rise to erroneous results. The practice at Mill Hill, where radioiodinated proteins are prepared, is therefore to use iodine-131 in the proportion of one atom per protein molecule, and to carry out the reaction under conditions that will ensure uniform reaction. Proteins react very rapidly with iodine at alkaline *p*H, one molecule of hydrogen iodide being eliminated for each iodine atom attached. Fast mixing is therefore necessary, and this is achieved by means of a microjet apparatus in which jets of protein solution and iodine solution flowing in opposite directions meet in a minute mixing chamber. The yield is usually of the order of 60 per cent of the theoretical, and the product is purified on an ion-exchange resin. The final solution as made available for research is isotonic, neutral, sterile and with less than 1 per cent of the radioactivity in the form of iodide ion.

Experiments have been carried out to ensure that the labelled plasma proteins so prepared cannot be 'recognized' by experimental animals. This work has been done by comparing the specific activity – time curves of radioiodinated proteins and biosynthetic $^{14}$C-labelled proteins. These were prepared by feeding high-specific activity $^{14}$C-algal protein to rabbits and then isolating the plasma proteins. It was found that the two curves nearly coincide, the difference between them being of very doubtful significance. A useful property of the radioiodine-labelled proteins is that the label is not re-utilized as is carbon-14. Whereas the metabolic products of $^{14}$C-labelled proteins are re-incorporated into new proteins, the iodine-131 is rapidly excreted once the protein has been degraded. This has the practical advantage that only the protein administered is being traced.

The application of an isotope technique to the assay of aldosterone and other steroids was described in a paper by Mr. R. N. Jones, Mrs. S. A. Simpson nd Dr. J. F. Tait, of the Middlesex Hospital, London, nd read by Dr. Tait. The assay method is based pon changes in the sodium–potassium ratio in drenalectomized rats caused by certain adrenal hormones, notably deoxycorticosterone and aldosterone. Two short-lived isotopes, sodium-24 and potassium-42, of half-lives 15·06 and 12·4 hr., espectively, can be employed for this purpose. The echnical problem which has to be met in this work s either the measurement of each isotope separately n the presence of the other, or the measurement of he ratio itself. This latter alternative has been found by these workers to be the better, and the method used is based on the fact that, whereas an absorber of thickness 300 mgm./cm. placed between the sample and the counter reduces the observed counting rate due to sodium-24 by a factor of 20, it reduces that due to potassium-42 by a factor of only 3. This fact can be applied successfully to the measurement of sodium-24/potassium-42 ratios, and carries with it the advantage that whereas both isotopes decay apidly, the ratio does not because they both have very nearly the same half-life.

The assay is carried out by reference to a graph of he logarithm of the ratio plotted against the ogarithm of the dose of steroid. Aldosterone is found o be 120 times more potent than deoxycorticosterone, which is used as a standard. The method, although very successful, was compared by Dr. Tait with a non-isotopic method, namely, the measurement of sodium–potassium ratios by flame photometry, and the opinion was expressed that in the long run the non-isotopic method would probably prove to be preferable.

Isotope dilution methods for the determination of cortisol and aldosterone, using the technique according to the principles described by Dr. Lester Smith, were also described. Ring-labelled cortisol and aldosterone di-(1-$^{14}$C)-acetate were used. The chief difficulty was in the purification of the extracted compounds, column chromatography being used.

The use of iodine-131 for another bio-assay was described by Mr. Trevor Kinnear of Edinburgh, whose paper was concerned with the assay of thyroid-stimulating hormone. His method is based on the effect of the hormone on clearance of labelled iodine from the thyroids of day-old cockerels. The chicks are injected first with iodine-131 and then, for several days following, with the sodium salt of thyroxine. Control groups are then injected with saline and other groups with various amounts of the hormone preparation to be assayed. The change in activity of the thyroids as measured *in vivo* indicates the rate of clearance of labelled iodine and is a measure of the activity of the thyroid-stimulating preparations.

Another method in which radioiodine is used was described in a paper by Mr. F. W. Jennings and Dr. W. Mulligan, of Glasgow. Their problem is to measure the volume of intracellular plasma in centrifuged red cells. Hæmatrocrit values as determined by the conventional methods are found to give very variable results, especially with the blood of cows and sheep. The isotope method adopted was based on the use of plasma proteins labelled with iodine-131 and subsequent measurement of the residual activity in the centrifuged cells. Variable results were still obtained with cows and sheep; but these were traced to the effect of temperature and time of centrifuging. More uniform results were obtained by the use of cooled centrifuges, the temperature being controlled at 15°.

Mr. F. P. W. Wintringham, of the Pest Infestation Laboratory, gave an account of some of the methods employed for investigating the biochemistry of toxic action in insects. His experimental animal is the common house fly, and at least one of his audience envied him the convenience of the size of his subjects, and admired the technique devised for experimenting upon them. Mr. Wintringham first pointed out that, in general, there are many dangers attendant upon the use of *in vitro* techniques, especially when toxic action is to be investigated. A given agent may inhibit particular enzymes *in vitro*, whereas in the living animal it may either never reach that enzyme or it may reach it by pathways which are absent in *in vitro* preparations. Since the well-being of the whole animal depends on the existence of metabolic pools the components of which are each within a particular range of concentrations, toxins cause accumulations or depletions of various components of these pools. It is to the study of metabolic pools and the action upon them of certain known toxins that an isotope technique coupled with paper chromatography has been successfully applied.

Mr. Wintringham took for his example the labelling of metabolic pools with phosphorus-32. When carrier-free $^{32}$P-phosphate is administered to the fly, all the metabolically active phosphorus-containing organic compounds become rapidly labelled. The fly is then killed and tissue extracts separated on paper chromatograms, and their presence and specific activities determined by scanning techniques. The effect of toxins on the labelling pattern is often spectacular. For example, the effect of methyl bromide is a large diminution in the size of the adenosine triphosphate pool and an increase in the size of the inorganic phosphorus pool. *Cyclo*propane, on the other hand (which is used as an anæsthetic during the injection of the flies), has no such effect. An interesting refinement of the technique is the confirmation of the specific activity of the phosphorus compounds: the original phosphorus-32 activity is allowed to decay away and the papers are irradiated in the pile, when all the phosphorus in the spots becomes radioactive by the $^{31}$P$(n,\gamma)^{32}$P reaction, thus giving, by its radioactivity, a measure of the amounts of phosphorus in the spots as would have been found by a chemical determination. By this means the interesting fact was confirmed that all the phosphorus atoms of adenosine triphosphate are labelled when phosphorus-32 is injected into house flies, whereas in mammalian tissues only the $\beta$- and $\gamma$-atoms are usually found to be radioactive. In answer to a question, however, Mr. Wintringham expressed the view that this does not constitute an important qualitative difference between the metabolism of insects and mammals, but is merely a reflexion of the higher turnover-rates in insects. He believes that, given time, all the phosphorus atoms of adenosine triphosphate in animal tissues would be exchanged; in fact, the similarities between the biochemical pathways of rats and flies are more striking than the differences.

The concluding paper of the meeting was a survey by Dr. J. F. Loutit of the dangers to health entailed in the manipulation of radioactive substances. In general, he was reassuring: only activities greater than 1 mc. of $\gamma$-ray emitters need be regarded as a danger so far as external radiation of workers is concerned, and these dangers can be controlled by the use of pocket dosimeters or film badges. Blood counts are much less satisfactory than such physical methods of measurement. Blood counts remain more or less constant until the subject has had a sufficient dose to produce irreversible damage and no institution in Great Britain now relies solely on this method of control. The dangers from internal radiation, which arise only when radioactive materials are inhaled or eaten, in general entail similar risks: that is to say, quantities of the order of 1 mc. inside the body are to be regarded as dangerous. But here, of course, the chemical properties of the isotope, which determine where it is deposited and how fast it is eliminated, its half-life and the nature of its radiations are also important considerations in assessing the dangers. The bone-seeking isotopes such as strontium are by far the most dangerous, as they irradiate the bone marrow. In concluding, and in answer to questions, Dr. Loutit expressed his opinion that emitters of soft β-radiation such as carbon-14, tritium and sulphur-35 are not particularly dangerous, and precautions similar to those taken b bacteriologists when dealing with pathogenic organisms would protect workers. He reminded th audience, however, that whereas pathogenic organisms accidentally let loose in the laboratory can b destroyed by disinfectants or other agents, radioactivity cannot be destroyed.

In attempting to assess the value of the meeting the present writer is under a difficulty. A symposiu devoted to technique rather than to a field of researc brings together workers on very different subjects whose common interest hangs on the somewha slender thread of common technique. A smalle proportion of those attending the meeting are therefore able to comment pertinently on each piece o research than occurs when the subject is common to all. There can be no doubt, however, that the meetings were much enjoyed by those present.

# NEWS and VIEWS

## Textile Chemistry at Manchester: Prof. R. H. Peters

THE Manchester College of Technology has trained students of textile chemistry ever since 1905, and the pioneer work of Prof. Knecht, of J. Huebner and of F. Scholefield is well known. The industry has always found great difficulty in recruiting skilled technologists, and it has sometimes failed for years to make full use of discoveries which have been made by the big firms and by research associations such as the Shirley Institute and the British Rayon Research Association. It is possible that if the textile industry of Britain could exploit the new synthetic fibres and the new methods of dyeing and finishing, it might have a chance of re-establishing something of its former position of pre-eminence in those world markets in which it cannot compete so long as it restricts itself to traditional fibres and the old-fashioned techniques which are now so well known to its competitors.

The appointment of Dr. Raymond Harry Peters to be the first professor of textile chemistry in the Manchester College of Technology may therefore prove to be of great importance to the textile industry as a whole. Dr. Peters obtained the degree of bachelor of science with first-class honours in chemistry at King's College, London, in 1939 and took his Ph.D. in 1942. He was in the Dyestuffs Division of the Imperial Chemical Industries, Ltd., at Blackley during 1941–47. He took a degree in mathematics in the University of Manchester in 1949 and then returned to Blackley. He became head of the Dyeing Research Section of I.C.I. in 1952. He has published a number of scientific papers and in 1953 he was awarded the medal of the Worshipful Company of Dyers. Prof. Peters will have at his disposal a splendid new dyehouse which has been very well equipped, thanks to the generosity of Courtaulds and the co-operation of a number of firms, in particular Messrs. Mather and Platt, Ltd. He should be able to build up a strong postgraduate research school in co-operation with local industry, and it is much to be hoped that his department will attract students who can be trained in this vitally important branch of technology, and so help the textile industry of Britain to bring itself up to date.

## Electrical Engineering at Swansea: Prof. W. Fishwick

THE chair of electrical engineering which was recently established at the University College of Swansea has been filled by the appointment of Dr. W. Fishwick, who is at present a lecturer in engineering in the University of Edinburgh. After obtaining first-class honours in the Mechanical Sciences Tripos at Cambridge in 1940, together with the Wynne Prize from Pembroke College, Dr. Fishwick joined the staff of the Telecommunications Research Establishment, where he was concerned first with the development of radar equipment and later with radio counter-measures. In 1944 he was commissioned for special duties with the R.A.F. and commanded a scientific intelligence unit operating in North-West Europe. Dr. Fishwick returned to Cambridge in 1946 as a research student under Prof. E. B. Moullin and Mr. C. W. Oatley, where he developed a novel type of mass-spectrometer using radar techniques which was capable of following very rapid changes in gas composition. Upon the completion of this work, for which Dr. Fishwick was awarded the degree of Ph.D., he took up a post with Imperial Chemical Industries, Ltd., at Manchester in 1948, where he was placed in charge of a laboratory for the development of instruments concerned with the automatic control of chemical plant. Two years later he was appointed to his present post at Edinburgh. Dr. Fishwick's more recent researches have been concerned with automatic control theory and with certain machine-tool vibration problems. It is peculiarly appropriate that the first occupant of the new chair should be actively interested in the field of automatic control, for many of the steel, chemical and other plants which are situated in the immediate neighbourhood of Swansea make extensive use of such controls.

## Social Responsibilities of Scientists

IN a paper presented to the American Philosophical Society (*American Scientist*, 43; July 1955), Prof. J. H. Hildebrand, of the University of California, examines the social responsibility of scientists. They should first try to extend the boundaries of knowledge and be able to answer Benjamin Franklin's question, 'Do you love truth for truth's sake, and will you endeavour impartially to find and receive it for yourself, and communicate it to others'?" They should in no way be blamed for not foreseeing every evil use to which their discoveries might be put; "those who decry science should come out into the open and say they prefer ignorance to understanding, darkness to light". Outside their scientific discoveries the mass of scientists are like the mass of other people with all the same human weaknesses and strengths. They should bear their moral responsibilities for the use or abuse of scientific discoveries with the rest of mankind.

## City and Guilds of London Institute

In the seventy-fifth annual report of the City and Guilds of London Institute, attention is directed to the launching of the ninth examining body, now officially known as the Associated Examining Board, for the General Certificate of Education. The establishment of the Board has been welcomed as one of the most significant developments in secondary education in recent years and a development which should undoubtedly prove to be of far-reaching importance in both educational and industrial fields. The new body is the only one of the nine now examining for the General Certificate of Education on which industrial and professional interests are directly represented, and the Board has therefore had in mind the production of syllabuses and the introduction of new subjects suitable for students intending to enter industry and commerce. The Council also reports progress in the number of candidates taking City and Guilds examinations, and of further requests for training courses. The number of candidates who sat for the Department's examinations in 1954 totalled 88,560—an increase of 6,273 over the previous year. Many new subjects were introduced during the year and major revisions of existing schemes were undertaken.

In the City and Guilds College the numbers of full-time undergraduate and postgraduate students have risen considerably; a chair of heavy electrical engineering and a readership in production engineering have been instituted, to be financed from the income which will be received from a share of the Counterpart Funds placed at the disposal of the University of London; and the first allocation of special expansion recurrent grant will allow for the appointment of a professor of applied science (engineering) and a professor of soil mechanics, in addition to other necessary additions to the lecturing staff.

## British Hat and Allied Feltmakers Research Association

The seventh annual report of the Director of Research of the British Hat and Allied Feltmakers Research Association (pp. 19 + 2 plates; from the Association, Manchester, 1954) covers the year ended August 1954 and refers to the fresh conditions of grant obtained for the five years commencing in April 1954. For the first two years the government grant remains unchanged, but for the following three years the industry is asked to raise an annual minimum of £12,000 to attract grant at the rate of £9,000 a year, with up to a further £5,000 on the basis of £100 for each £100 in excess of the stipulated minimum raised by the industry. One of the Association's outstanding achievements has been the development of equations for carrotting fur, although further work and factory trials will be necessary to establish their validity for all grades of fur and different types of carrotting reagents. So far, different equations have been established for the standard 'mercury in nitric acid' reagent and for non-mercuric reagents of the 'hydrogen peroxide–nitric acid' type. The study of wool noil, of the directional felting of wool and the physical properties of fibres continued, and the operation of multi-roller machines in relation to the degree of carrotting and the grade of fur used was investigated. The survey of wool bumping machines has yielded information on the loading of crank bumpers in relation to the wetness and temperature of the mass, and to the rate of felting, which should find immediate application in the industry, while observations on the time of dyeing of wool felt were immediately reflected in the quality of the hats produced. *Ad hoc* research programmes included the blending of fur with protein fibres, the shower-proofing of hats and the stoving temperature in carrotting fur. Other work has been concerned with standardization of raw materials and finished products. A research conference held in conjunction with the annual general meeting, at which papers reviewing the work of the Association were delivered, was an outstanding success.

## Finnish Institute for Occupational Health

The Board of Trustees of the Institute of Occupational Health in Helsinki is made up of members of the Cabinet, the universities and voluntary organizations. Its funds are drawn from industry, insurance companies and workers' organizations and, each year, it publishes a report in English (Occupational Medical Foundation and Institute of Occupational Health. Annual Report, 1954. Pp. 47. (Helsinki: Occupational Medical Foundation and Institute of Occupational Health, 1955)). Besides a general department, it has medical, physiological, psychological and industrial hygiene departments and, in 1954, the number of workers engaged on research projects increased substantially compared with the previous year. Among the original investigations carried out was one into the problem of sickness absenteeism among government workers. Of 44,000 government workers whose cases were examined, the frequency of sickness among groups working indoors has been three times higher than that among outdoor workers. A study of the characteristics of an influenza epidemic and of the effects of immunization showed that previous attacks of influenza had no clear immunizing effects, while the results obtained from immunization were unsatisfactory. Investigations were also made into the reasons why javelin throwers have to give up their sport each year for varying periods, while a statistical study was also made into the relation between age and number of traffic accidents incurred by some five hundred bus drivers. This showed that the number of accidents involving drivers with long experience diminishes with age up to approximately 45–48 years, after which the accident-rate begins to grow.

## Macaulay Institute for Soil Research: Report for 1953–54

The annual report for 1953–54 of the Macaulay Institute for Soil Research, Aberdeen (pp. 55 + 2 plates; from the Institute at Craigiebuckler, Aberdeen; 1955), indicates that the Institute continues actively to promote its aim of advancing the fundamental study of the soil in all its aspects. The Pedology Department surveyed a further 260 square miles of Scottish soils, and continued the study of conditions and practices on upland grazings with special regard to heather management. Improvements of existing analytical methods are reported by the Department of Spectrophotometry, and the use of a double-beam infra-red spectrometer has assisted the positive identification of some substances present in soil organic matter. Investigations on the carbohydrate and nitrogenous constituents of the soil have been continued by the Department of Soil Organic Matter. Other activities of this Department include studies in the transformation of fatty materials in the soil by Actinomycetes, the physiology of aerobic thermophils, lignin decomposition studies and work on peat classification, including pollen analysis. The Department of Plant Physiology, working with sugar-beet disks, finds that phosphate absorption is related to the reducing-sugar content of the cell. It is also suggested that the ratio of phosphorus to iron in leaves gives a clearer picture of the iron status of plants than the individual concentration of these elements, high ratios being characteristic of iron-chlorotic plants. Investigations of soil fertility directed towards improving fertility practice, clarifying the significance of soil properties in relation to crop production and developing methods for evaluating the nutrient status of soils, have been continued.

## Journal of the Institution of Telecommunication Engineers, India

THE first number of the *Journal of the Institution of Telecommunication Engineers, India* (see *Nature*, July 16, p. 100), was published in March, and for the present it will be produced as a quarterly (from the Institution, Curzon Road, New Delhi; Rs. 15 a year or Rs. 5 per copy). It is intended that each issue of this *Journal* will normally comprise an editorial note, two or three research papers, articles of general interest for students, reviews of papers, news and notes, and letters to the editor. The first number contains the texts of the addresses delivered at the inaugural session of the Institution on November 2, 1953: first, the address of welcome by A. C. Ramchandani, chief engineer of All-India Radio; next, the inaugural address by Dr. S. Radhakrishnan, vice-president of the Republic of India; and then the presidential address by B. R. Batra, chief engineer of the Posts and Telegraphs Department. Mr. Batra's second presidential address, delivered on December 12, 1954, is also reproduced. The more technical material published in this issue comprises an article on line fault location by pulse technique, by T. K. Mahadevan; an account of radio measurements at Jabalpur during the solar eclipse of June 30, 1954, by members of the Government Engineering College at Jabalpur; and a paper by S. Sampath on power density diagrams of short-wave aerial arrays. The *Journal* concludes with the annual report of the Council of the Institution for 1953–54, and a list of current members.

## Anguinomorph Lizards

IN 1878 Steindachner described a lizard from Sarawak which he named *Lothanotus borneensis*. Only a few specimens have been collected since then, so that it is still rare in museums. As it was regarded as closely related to *Heloderma*—indeed, it was sometimes put in the same family—it presented a remarkable example of discontinuous distribution. S. B. McDowell, jun., and C. M. Bogert in "The Systematic Position of *Lothanotus* and the Affinities of the Anguinomorph Lizards" (*Bull. Amer. Mus. Nat Hist.*, 105, Art. 1, 1954; pp. 142+43 figs.+6 plates 6 dollars) started to examine this problem but were soon led into wider fields and examined the crania of 306 living reptiles and those of eight related fossi genera. This work is illustrated, *inter alia*, with the detailed drawings of the skulls of twenty-eight species of reptiles, and as the majority of these are origina they furnish a very valuable series for reference These and the other text-figures are excellently drawn and well reproduced. In addition to the claim that *Lothanotus* is allied to *Heloderma*, Nopcsa suggested that it also resembled *Shinisaurus crocodilurus* another rare lizard from southern China, and this point is also specially investigated. The procedure adopted is to give full accounts of the externa features, skulls, and post-cranial skeletons of these species and of the classical lizard genus *Varanus*, and then to make detailed comparisons between them and a series of key forms. Among the conclusions reached is that the Anguinomorpha, as here defined, include the extinct Mosasauridae and constitute a natura infra-order divisible into two superfamilies, the Diploglossa and the Platynota. *Shinisaurus* belongs to the former and, although *Heloderma* falls in the latter, it is in a separate family not closely related to the Lothanotidae. Some of the characters of *Lothanotus* are such as might be expected in a form ancestral to snakes. It is further suggested that the Typhlopodidae should not be included in the Ophidia but should be regarded as a highly specialized line of Anguinomorph lizards the resemblances of which to the snakes result from convergence. Altogether, this is a most useful contribution upon which the authors are to be congratulated.

## Biological Races of *Phytophthora Infestans* in Canada

IN recent investigations of the *Phytophthora* blights of tomatoes and potatoes in eastern Canada, it was found that different isolates of the fungal pathogen did not always yield reproducible effects in inoculation experiments. This led to the view that different biological races of the fungus might be involved—a view fully borne out by further experimental work now reported by K. M. Graham and H. N. Racicot (Soc. de Quebec pour la Protection des Plantes, Thirty-fifth Rept., p. 50; 1953). Thirty-one isolates of *P. infestans* from potatoes were examined. Cytological study showed that the zoospores are uninucleate and that genetically pure lines could therefore be obtained, these being cultured on oatmeal agar. On a host-range comprising both potato and tomato varieties, it was found in comparable inoculation tests that three races of the pathogen could be differentiated, their respective effects being indicated.

## Photosynthesis in Different Phyla

L. Norris, R. E. Norris and M. Calvin have reported on a survey of the rates and products of short-term photosynthesis in plants representative of nine different phyla (*J. Exp. Bot.*, 6, 16, 64; 1955). When short-term experiments on photosynthesis, using carbon-14 dioxide and paper chromatography, were performed with twenty-seven different plants representing nine phyla, there was a remarkable uniformity in the types of ethanol-soluble compounds which became radioactive in the entire group of plants used. The percentage amounts of the different compounds varied considerably among the various

# BRITISH ASSOCIATION MEETING AT BRISTOL

## SCIENCE AND THE SCIENTIST*

By Sir ROBERT ROBINSON, O.M., F.R.S.
President of the British Association

HE Association held its sixth annual meeting in Bristol in August 1836 under the presidency of Marquis of Lansdowne. No significance need be ached to the fact that the well-known riots urred here in the following year, which is much tter dated by the accession of Queen Victoria. I ted from the report with interest and a certain stful approval that the address was delivered on at occasion not by the president but by Charles ubeny, Fellow of Magdalen College, Oxford, local asurer for Oxford. Daubeny had already been pointed to the University chairs of chemistry and botany. He was well qualified to profess geology o; but his eventual third chair was that of rural nomy. He was a founder member of the Associa- n and had attended the five previous meetings. ndoubtedly one of the chief pioneers and benefactors science in Oxford, he was a man of great originality d tireless energy. Among many notable contri- tions to knowledge, one that deserves the epithet ssical was his discovery that the process of photo- nthesis occurred more rapidly under the influence blue and violet light than under that of the less rangible rays.

In the course of his address, Daubeny referred, ong other things, to various systems of notation chemistry and mentioned in that connexion Dr. hn Dalton, whom he described as the 'venerable' nder of the atomic theory but who was in fact st short of seventy years of age. At the meeting of Association in the previous year at Dublin, lton had given an account of his experiments on distillation of caoutchouc and of the formation a volatile oil which was doubtless crude isoprene. is he called 'double olefiant'. One volume of the porized substance exploded with six volumes of ygen gave four volumes of carbonic acid gas, which rks out for:

$$C_5H_8 + 6O_2 = 4CO_2 + 3H_2O + (CH_2O).$$

re the $CH_2O$ merely represents loss of partly idized hydrocarbon. I mention this matter, rather t of context, because the work seems to have been gotten.

Dalton was not too 'venerable' either to be a vice- sident of the Chemistry Section at the Bristol eting, or to be charged with the duty of examining lesser constituents of the atmosphere. One nders whether the small incombustible residue ted by Cavendish, and which was undoubtedly gon, was known to him.

The next meeting at Bristol was in 1875. The sident was the eminent engineer Sir John Hawk- w, and he delivered a most interesting address on historical development of achievement made ssible by applications of engineering and other ences. The last three sentences will interest you. . . Need we try to extend our vision into futurity ther? Our present knowledge, compared to what is unknown, even in physics, is infinitesimal. We may never discover a new force—yet, who can tell ?"

The meeting was attended by many famous men of science, and among the officers of sectional committees we find Cayley, Thomson (afterward Lord Kelvin), Tyndall, Rayleigh, Williamson, Galton, Armstrong and Tilden; a short list at random that could be greatly extended.

Sir William Crookes was the president at the third Bristol meeting, in 1898, and he delivered an outstanding address on a variety of topics. First on the gloomy prospects for the supply of bread to the people of the British Isles. Here he foresaw with characteristic intuitive genius that the only possible solution would be to obtain nitrogenous products from the atmosphere. At that time the only known method was the combustion of nitrogen with the help of a powerful electric discharge, an experiment initiated by Henry Cavendish, developed by Crookes himself in 1892, and by Rayleigh for the isolation of argon. Crookes even calculated that electricity generated from coal could be used to produce sodium nitrate at £26 per ton and that power from Niagara would reduce the cost to £5 per ton. The figure for Chilean nitrate was £7 10*s*. per ton, estimates which have only relative interest at the present time. If the Haber synthetic ammonia process had not offered a much better alternative, it is possible that Crookes's idea would have been commercially developed. In any event, his thoughts were along the right lines.

Crookes was able to report that on May 10, 1897, Dewar had written to him: "This evening I have succeeded in liquefying both hydrogen and helium." Further, he mentioned that in the preceding few months, Ramsay and Travers (a distinguished Bristolian) had discovered three new rare gases of the atmosphere.

He goes on to speak of X-rays and the early discoveries of radioactivity by the Curies and Becquerel. Speculating on the source of the energy unceasingly radiated, he found it in the translational motion of the molecules and of the atoms within the molecules. He was thus led to the considerable under-estimate that the air in a room of moderate size "contains energy enough to propel a one-horse engine for more than twelve hours", and continues, "The store drawn upon naturally by uranium and other heavy atoms only awaits the touch of the magic wand of Science to enable the Twentieth Century to cast into the shade the marvels of the Nineteenth." How much more true that is than Sir William Crookes imagined.

His final section on psychical research and experimental psychology was restrained but confident. He was conscious of the criticism which he was inviting but did not shrink from giving witness to his conviction that the phenomenon of telepathy, for example, was a real one and that the subject should be studied by scientists.

May I now interpolate that we should all agree with this. Telepathy, and even pre-cognition, are claimed to have been established, and surely it is extremely important to know whether the evidence

---

Presidential address delivered at Bristol on August 31 and appearing he September issue of the *Advancement of Science*.

is really good enough to justify these claims. In the first place, we need to discuss how to set to work, and only when that is quite clear to put a plan into operation. It is the first stage which is likely to be the more difficult. Perhaps it should be added that no final verdict can be anticipated. As Dr. Warren Weaver has so aptly remarked, there is no such thing as the voice of science.

The last Bristol meeting was in 1930, with Prof. F. O. Bower as president. He spoke on "Size and Form in Plants" and remarked that this ninety-ninth year of the life of the Association marked the close of the Darwinian epoch. That was intended only in relation to personal links and did not imply that Darwin's influence on science had in any way lessened. Bower naturally referred to Sir William Crookes's remarkable address of 1898 and was able to point not only to the actual production of artificial fertilizers but also to the development of new strains of wheat which enabled areas of lower rainfall to be utilized, and also shortened the period between sowing and reaping.

So far, in asking for your attention to the reverberations of the thunder of the past, I have been on solid ground; but now the situation changes as I turn to my own choice of a topic. I recall the case of the Texas politician who was said, naturally by an opponent, to have "both feet firmly planted in the air". However, even if this is thought to apply, I hope to come to earth occasionally.

One of the troubles of the modern life of scientists is that we are all too busy, and that only a small fraction of our available time and energy can be spent in practising our real vocation. Please forgive a personal reference—it is not really very boastful. I am conscious of a certain talent for tapping a test-tube; but it is a long time since I was able to indulge this bent to much purpose. Lately I have had to be content to encourage others to perform this simple operation with, it should be added, due consideration of what is placed in the test-tube, and observation of what happens.

When the secretary of the British Association, as agent of the Council, asked me for the title of this address, I was more than usually preoccupied and selected "Science and the Scientist", because I thought it clay that could be modelled into almost any desired shape.

However, there was at the back of my mind the feeling that the functions of the two are not always clearly understood and distinguished, so that there is more than a little confusion of thought in some quarters, especially in the use of the word 'science'. The subject is not at all controversial; but I will ask for your indulgence to state once more the generally accepted definition, clearly implied in common consent if not the subject of any recent manifesto.

## The Broad Definition of the Term Science

Science is simply the record, enshrined in the literature, of the system of knowledge and of the conceptions correlating parts of that system.

It is fundamental that such knowledge cannot be based on dogma or authority of any kind, nor on any intuition or revelation, unless indeed it be of the Book of Nature that lies open before our eyes. We need not dwell on the processes of acquiring knowledge by observation, experiment, and inductive and deductive reasoning. The study of scientific method both in theory and practice is of great importance; but this topic requires separate treatment. Furth
it is inherent in the philosophy that the record m
be imperfect and the conceptions erroneous;
potential fallibility of our science is not only ackno
ledged but also insisted upon.

## Approximation to Truth

Still there are degrees of uncertainty, and even
apparent revolution in physics that has occurred
the twentieth century has not so much supersec
the older teaching as supplemented and extended
by wider generalization.

The improvement of knowledge by success
approximations is fundamental, and it is worth wh
to consider some illustrations.

A very simple example of the improvement o
nearly true statement of a relation is that of
Boyle–Charles law. This stated that the volume o
gas is directly proportional to the temperature a
inversely proportional to the pressure. It can
expressed as $pv = RT$. This works very well
most practical purposes; but it is not quite corre
especially at higher pressures. In 1873 van
Waals pointed out that the volume ($v$) taken sho
be lessened by a quantity ($b$) related (but not eq
to) the volume of the molecules themselves, that
$v - b$ for $v$. The pressure ($p$) should be increased
a quantity $a/v^2$ which denotes the cohesion of
molecules.

With the expression,

$$\left(p + \frac{a}{v^2}\right)(v - b) = RT,$$

a much better agreement with the experimental da
was obtained; but it was still not absolutely accur
and more or less successful modifications have be
suggested.

The 'ideal' gas which obeys the Boyle–Charles l
may perhaps be compared to the 'ideal' railway th
conforms to "Bradshaw". The divergence from
ideal in the performance of a railway becomes grea
when the traffic is congested, and this factor is
unlike the $b$ of van der Waals. But railways
much worse than gases, chiefly due to the appeara
of the human factor, which is quite incalculable.

## An Example to Illustrate Limits of Knowled

Where the material can be directly apprehen
by our senses, aided perhaps by devices such
cameras, microscopes and telescopes, there can
little doubt as to the validity of the record; thou
it may need some adjustment of errors of observat
and of the value of any magnitude that is involv
The uncertainties are then largely concentrated
the conceptions and generalizations which have b
based on the ascertained facts. May I be excuse
I refer to the subject I know best in illustrati
The molecular structures of the chemist are
directly perceptible, but must be deduced fr
observations on collections of very large number
molecules; and yet a most remarkable system
been evolved which even forms the conventio
basis of patents and is recognized as valid in co
of law. The degree of uncertainty is indeed not m
increased by the fact that we cannot see th
structures.

Leaving aside philosophical dubieties about real
we can say that the limits of our knowledge in
field are somewhat as follows. That the atoms e

entities, but the problem of the nature and con- ution of the atoms themselves has not been fully ved; rapid progress is being made. We know the angement of the atoms in the vast majority of the cies of molecules which we find in Nature, and we e learned how to construct molecules, even those a highly complex pattern. The defences of some he last strongholds are in process of being breached. brilliant example of modern work of this kind is ng described by the president of Section B (Chem- y), Sir Alexander Todd. It concerns the structure l synthesis of the nucleosides, those vastly im- tant constituents of the nuclei of living cells. en the proteins are being forced to reveal their rets, and though none of them has yet been thesized, we have a foretaste of what is in store the artificial preparation of the oxytocic factor of pituitary by Prof. V. du Vigneaud. And when speak as chemists of nucleosides, proteins, or the tocic factor, we are all the time thinking not so ch of the specimen in the glass tube but of the y the atoms are joined together in each of the ions upon billions of molecules in the tiniest ible fragment of the material. May I be pardoned the *cognoscenti*, I cannot forbear from repeating results of a calculation made by Dr. Harlow pley, the eminent American astronomer, which strates very clearly the huge number of the lecules in any small parcel of matter. In any ume of air four-fifths of the particles are molecules nitrogen, each consisting of two atoms. If, for mple, a deep breath is exhaled, the nitrogen lecules in it are rapidly dispersed and, after a tain period, probably not more than a few years, haps less, they will be equally distributed through- the atmosphere. The mass of the atmosphere is wn approximately, and when even distribution been achieved, each unit volume of air at the face of the earth will contain between two and ee of the nitrogen molecules that were present in original volume distributed. Now to make it re dramatic we select some particular exhalation, ferably a long time back so as to make sure of necessary even diffusion. Thus we could say t when Shakespeare was writing the first line of second act of *Hamlet*, he exhaled a breath; and you care to inhale a breath now, it will contain of the actual molecules exhaled by Shakespeare that particular time. You would be very unlucky ou only got one and, if you were to capture three, would belong to a fortunate minority.

he calculation leads to other interesting results. you exhale a breath now, then, after the lapse of necessary time, every breath inhaled by every ng person on all occasions will contain two of the rogen molecules in that breath of yours.

t must be obvious that many of the molecules be used more than once, and the calculation es no account of the small losses from the atmo- ere due to escape, or the activities of Sir Alexander ck, among other nitrifying organisms.

he question which is often asked, and ought to asked, is: How can you possibly know anything ut the architecture of such exceedingly minute ticles? The answer cannot be given in a few tences but an analogy may help you to appreciate possibility—again with apologies to those *cogno- ti*. A pure chemical substance is a collection of tical molecules. Let us compare a perceptible unt of it to a crate of identical clocks; each k then represents a molecule. We reduce the clocks to a heap of metal filings, take a certain weight of these and apply a strong magnet. This takes out the iron, which we weigh, and thus we get the percentage of iron in the whole of the clocks, which is also the percentage of iron in one clock. But it may be objected, you have started with the hypothesis that the molecules in a parcel of a pure substance are identical. How can you be sure of that? A short answer cannot be given; it depends on the recognition that certain properties, for example, many optical properties, are due to the summed effects of individual molecules, and on the elaboration of techniques for segregating molecules of the same kind; for example, by crystallization, distillation, diffusion, or by adsorption on surfaces.

## Predictions and Conveyances

Justification of scientific theory has been obtained by the success of predictions and by the unanticipated convergence of more than one line of approach. This is a commonplace of every part of science, and the examples to be mentioned could be almost indefinitely extended. In all the cases the degree of coincidence becomes so great as to carry conviction that we have been vouchsafed, if not the whole truth, at least something very closely related to it.

Even the routine predictions of astronomers are a perpetual source of wonder; but the circumstances of the discovery of Neptune were sensational. In 1843–44, J. C. Adams, of Cambridge, found that the perturbations of the orbit of Uranus could be fully explained by the existence of an outer planet and he accurately identified the position in which it should be found.

Quite independently, Le Verrier, of Paris, came to exactly the same conclusions and was more fortunate than Adams in securing the quick co-operation of practical astronomers, with the result that Neptune was discovered in the predicted place in the heavens. It proved to be of the size expected and later was found to follow the expected orbit.

Again, near the beginning of the second decade of the century, Albert Einstein stated that his relativity theory required that the rays of light should be bent under the influence of a gravitational field. He was able to calculate the magnitude of the expected effect. Confirmation came from observations made on the occasions of the two next following total eclipses of the sun. This success was naturally particularly welcome in view of the novelty of the theoretical background, and it doubtless accelerated the development of the new physics based on the work of Planck, Einstein and other pioneers.

The death of Einstein has evoked universal tributes of homage to the man and the philosopher. He was undoubtedly one of the greatest of men of science.

A third example of prediction is the successful release of nuclear energy, especially in the so-called hydrogen bomb. We must not allow the horror of the possible misuse of the weapon to blind us to the spectacular triumph of the achievement. It showed very plainly that nuclear physicists had been thinking on the right theoretical lines. Let us hope that they will continue to do so—100 per cent and not 99·9 per cent. These matters are shrouded in secrecy; but Press reports have suggested that just as the hydrogen bomb is initiated by a Mark-I atomic explosion, so the hydrogen bomb in its turn can initiate a vastly greater uranium explosion. In biological processes energy is taken up in steps by suitable relays to high levels, and an ordinary scientist cannot help wondering whether every possibility of setting fire to the lighter elements has quite certainly been excluded, if nuclear relay is taken to further stages.

Do we really know enough about nuclear reactions to be sure there is no loophole ? Has every conceivable case been considered ?

The physicists appear to be cocksure that this is so ; they claim the 100 per cent. But just as it is necessary that 'justice shall be seen to have been done', I submit that it is desirable that the inner circle of advisers to Governments should not only be right but also be 'seen to be right'. This can only be secured by a relaxation of secrecy on the scientific aspects of nuclear energy developments, and by some form of international consultation before novel and greatly increased releases of energy are attempted.

The second class of welcome confirmations was the illumination of a topic from two or more distinct sources.

This is now a commonplace of many sciences, for example, again, of organic chemistry. Analytical researches lead to the determination of a molecular structure which may be confirmed, possibly after the lapse of years and in a different laboratory, by synthesis of the substance the molecules of which should possess that structure. If the synthetic product proves to be identical with that isolated from natural sources, the whole system of reasoning both on the analytical and synthetic sides receives important support. Even more striking has been the validation of the conclusions of chemists by X-ray crystallography. At first this led to the confirmation of established structures, often with some additional information about the arrangement of the atoms in space. Later the X-ray studies were accessory to the first analytical studies. Thus in the case of penicillin, Mrs. Hodgkin and her collaborators were able to fasten upon one of the two alternative structures which the purely chemical researches indicated. Now the chemical and physical methods go hand in hand, with the crystal analysis tending to take a more important role than in the past, and destined to do so more and more in the future.

Another example may be mentioned. The chemical formula for a metal phthalocyanine had the shape of a four-leaved clover and the metal atom was placed at the centre. J. M. Robertson's electron-distribution diagram from X-ray evidence had the same discoid shape and the metal atom was where expected. Only a few years ago a special electron microscope cast the clover-leaf shadow of a single molecule of copper phthalocyanine on a fluorescent screen. The necessary apparatus is not particularly complicated and can be purchased.

This was by no means the first time that a single molecule had become apparent to our senses. Owing to the great energy of certain particles carrying an electrical charge, and the invention of devices for amplifying very small currents, we have long been familiar with a variety of methods for observation of the effects of single particles : Crookes's spinthariscope, the Geiger counter, the Wilson cloud chamber and—bringing coals to Newcastle—the techniques developed in such an admirable manner by Prof. C. F. Powell and his school in Bristol, for the study of single events at the atomic level—the study of the impact of cosmic rays on the sensitive emulsions of the photographic plate.

In other subjects there are very many examples of the confluence of streams springing from two sources.
Examples are the dating of ancient objects by mea
of radioactive isotopes and the light shed on t
movements of races by the hybridization of plan

The latter reference is to a hybrid cotton pl
found in Peru. There the Porto Rican cotton pl
married the Indian, and the circumstances are c
sistent with the view that Indian voyagers reach
South America in very early days.

## Scope of Science

All branches of knowledge are included in t
definition of science ; always provided that t
record has been made without appeal to authori
There is no philosophical line of demarcation th
separates one branch of learning from another, thou
the demeanour of many so-called humanists sugge
that they perceive one.

A historian, formerly a colleague of mine, o
declared that the absorbing interest of his subj
was due to the badness of the evidence ; but I th
that was only another way of saying that he liked
get his teeth into a difficult problem.

It is not necessary or desirable to pursue t
unprofitable discussion ; our brother scientists on t
Arts side will doubtless work out their own salvati
But it is opportune to add another voice of prot
against the often repeated assertion, that 'culture'
the preserve of students of some particular branch
of knowledge, and is denied to others. What is mea
by 'culture' ? If it is the ability to think clearly a
to express thoughts in language, what evidence
there that physical and biological scientists la
these qualities ?

The acerbity that characterizes much of the an
scientific propaganda strongly suggests that its ba
is defensive rather than offensive.

In the meantime, these persistent attacks do
great deal of harm by suggesting to young peo
that they will become automatons if they dev
themselves to physical science and that in such a l
they will not experience the warmth of hum
feeling.

## The Joy of Discovery

What a travesty of the facts this is ! The scienti
discipline is indeed a hard one ; but it is most rewardi
and full of living drama. Perhaps I may just ha
time to show one picture from the past. It concer
a beginner in research, but that young man was Lo
Pasteur. It will be best to quote his own words fr
"Lectures on the Molecular Asymmetry of Natu
Organic Products" (1860), reprinted by the Aleml
Club of Edinburgh :

"When I began to devote myself to special wo
I sought to strengthen myself in the knowledge
crystals, foreseeing the help that I should draw fr
this in my chemical researches. It seemed to me
be the simplest course, to take, as a guide, so
rather extensive work on crystalline forms ;
repeat all the measurements, and to compare
determinations with those of the author. In 18
M. de la Provostaye, whose accuracy is well kno
had published a beautiful piece of work on t
crystalline forms of tartaric and paratartaric ac
and of their salts. I made a study of this memo
I crystallized tartaric acid and its salts, and inve
gated the forms of the crystals. But, as the wo
proceeded, I noticed that a very interesting fact h
escaped the learned physicist. All the tartrates whi

xamined gave undoubted evidence of hemihedral es.

'Now if we compare the disposition of the hemi- dral faces on all the prisms of the primitive forms the tartrates, when they are orientated in the same nner, this disposition is found to be the same."

Herschel had already connected the hemihedry of artz with the right or left rotatory power of the stals, and Pasteur saw that the hemihedry of the trates could be an outward and visible sign of the ymmetry of the molecules. Hence he was extremely erested in a note of Mitscherlich of 1844 stating at sodium ammonium tartrate and sodium ammon- n paratartrate had identical crystal form and yet ly the former was optically active in solution. He ought Mitscherlich must have failed to notice that e paratartrate was not hemihedral.

"I hastened therefore to re-investigate the crystal- e form of Mitscherlich's two salts. I found, as a atter of fact, that the tartrate was hemihedral, like the other tartrates which I had previously studied, t, strange to say, the paratartrate was hemihedral o. Only, the hemihedral faces which in the tartrate re all turned the same way were, in the paratrate inclined sometimes to the right and somenes to the left. In spite of the unexpected character this result, I continued to follow up my idea. I refully separated the crystals which were hemi- dral to the right from those hemihedral to the left, d examined their solutions separately in the polarng apparatus. I then saw with no less surprise an pleasure that the crystals hemihedral to the ht deviated the plane of polarization to the right, d that those hemihedral to the left deviated it to e left; and when I took an equal weight of each the two kinds of crystals, the mixed solution was different towards the light in consequence of the utralization of the two equal and opposite indi- dual derivations.

"The announcement of the above facts naturally aced me in communication with Biot, who was not thout doubts regarding their accuracy. Being arged with giving an account of them to the ademy, he made me come to him and repeat before s eyes the decisive experiment. He handed over to e some paratartaric acid which he had himself eviously studied with particular care, and which had found to be perfectly indifferent to polarized ht. I prepared the double salt in his presence, with da and ammonia which he had likewise desired to ovide. The liquid was set aside for slow evaporation one of his rooms. When it had furnished about 39 40 grams of crystals, he asked me to call at the llège de France in order to collect them and isolate fore him, by recognition of their crystallographic aracter, the right and the left crystals, requesting e to state once more whether I really affirmed that e crystals which I should place at his right would viate to the right, and the others to the left. This ne, he told me that he would undertake the rest. e prepared the solutions with carefully measured antities, and when ready to examine them in the larizing apparatus, he once more invited me to me into his room. He first placed in the apparatus e more interesting solution, that which ought to viate to the left. Without even making a measureent, he saw by the appearance of the tints of the o images, ordinary and extraordinary, in the alyser, that there was a strong deviation to the left. Then, very visibly affected, the illustrious old man took me by the arm and said :—

"'My dear child, I have loved science so much throughout my life that this makes my heart throb.'

"You will pardon me, gentlemen, these personal recollections which have never been effaced from my mind. In our day, and with our habits, they would offend in a scientific memoir, but they have seemed to me not out of place in an oral account; and perhaps the biological interest of such recollections will constitute one of the advantages of the kind of instruction which the Société Chimique inaugurates to-day.

"Indeed there is more here than personal reminiscences. In Biot's case the emotion of the scientific man was mingled with the personal pleasure of seeing his conjectures realised. For more than thirty years Biot had striven in vain to induce chemists to share his conviction that the study of rotatory polarization offered one of the surest means of gaining a knowledge of the molecular constitution of substances."

Thus was the science of stereochemistry born. The main point of Pasteur's work was that he recognized that the optical rotatory power of the tartrates in *solution* showed that the molecules themselves must be asymmetric. The hemihedry of quartz was recognized as due to the asymmetrical arrangement of symmetrical molecules in the crystal, like a right- or a left-handed screw. But the hemihedry of the tartrates, though due in the crystal to the same cause, persisted in the free molecules, which were therefore characterized by asymmetry in a certain sense, all right-handed or all left-handed. A mechanical analogy is very useful here. If a pipe is almost filled with one screw and water is forced along it, the issuing stream will rotate, clockwise or anticlockwise, according to the nature of the screw. The same thing happens if we pack the tube with small right-handed screws, or left-handed screws, arranged at random. With an equal number of both kinds there would be no rotation of the issuing water. The single large screw corresponds to the quartz crystal, and the higgledy-piggledy small screws correspond to the freely moving asymmetrical molecules of the tartrate in solution.

The philosophy of asymmetry is very intriguing. Only an asymmetric, I should perhaps say dissymmetric, agent can distinguish the right-hand from the left-hand varieties, and of course it was Pasteur himself who sorted out the hemihedral crystals oriented in the two mirror-image forms.

Recently, by a most ingenious application of crystal analysis, Prof. J. M. Bijvoet has been able to determine the configuration of naturally occurring tartaric acid, which is related to that of many other substances in what we call the L-glucose family. The convention used by stereochemists turned out to be correct, which is quite convenient. The chances for this outcome were naturally no better than even.

Admittedly this example of 'atmosphere' relates to a very exceptional occasion and Pasteur was a very remarkable man, one of the greatest scientists of all time.

But all of us who have been privileged to take part in scientific life and research have had similar exciting and may I add, emotional, experiences in our smaller ways.

The explanation of molecular asymmetry in terms of structure was given in 1875 by Le Bel and independently by van 't Hoff. The latter was said by Kolbe "to have no taste for exact science. Mounted on his Pegasus, evidently borrowed from the veterinary stables (van 't Hoff taught chemistry at the College of Veterinary Science at Utrecht) he thinks he can see the arrangement of the atoms in space". Nowadays the organic chemist has not completed a synthetic task until the various parts of the molecule have the desired type of asymmetry. Often a succession of screws has to be laid down in the correct order. Thus there are eight places in the cholesterol molecule which can be the source of asymmetric arrangement and that implies 256 possibilities of difference due only to the right- or left-handedness of the parts. Yet the one particular configuration of the cholesterol molecule has been constructed in the laboratory.

The task was equivalent to finding the right road at each of eight successive bifurcations.

Before straying too far from actual science I would like to say something about the use of speculation, which should always arise from some correlation which was hitherto unknown or unnoticed, or the significance of which has been under-estimated, or thought to have been under-estimated.

In the early stages it may be discouraging to study the literature; one can always find reasons there for believing that a new idea is not worth pursuing, or for that matter for saving oneself the trouble of doing an experiment. Later, having worked up an internal, self-generated pressure of enthusiasm, it is obligatory to face the hard facts already on record. Then, instead of weakly accepting a rebuff we shall at least put up some fight with 'but on the other hand it might be that——'.

At this point it may be realized that something really has been overlooked by one's predecessors, and new crucial experiments must be devised to resolve one dubiety after another. Herein lies the safeguard, the final court of appeal is Nature herself.

The scope of the British Association's interest is not clearly defined in our original "Objects" which I will read, because the early practice of printing them each year has long been abandoned.

"The Association contemplates no interference with the ground occupied by other institutions. Its objects are:—To give a stronger impulse and more systematic direction to scientific inquiry,—to promote the intercourse of those who cultivate Science in different parts of the British Empire, with one another and with foreign philosophers,—to obtain a more general attention to the objects of Science, and a removal of any disadvantages of a public kind which impede its progress."

Our sections now include the chief physical and biological sciences, economics, anthropology and archæology, psychology, and education, as well as engineering, forestry and agriculture. There is also an active Division for the Social and International Relations of Science. All this evinces a real catholicity of interest; omissions are based on practical, rather than on theoretical considerations. For example, clinical medicine and surgery are well served by a number of other organizations.

## The Universality of Science

An important aspect of science is its universality and its fully international character only rendered possible by the axiomatic freedom it enjoys from authority and dogma. True there have been regrettable incidents such as that of the Michurinian genetics, but the body scientific has acquired considerable immunity against such fevers, which are now all b forgotten.

There is no such thing as British, or German, Russian, or Jewish science, though it is true that th genius of many peoples has enabled them to mak characteristic contributions. The French have special lucidity of mind and expression, as well elegance of technique, the Americans excel in orga ization of research, the Germans in thoroughness, th Japanese in attention to detail, while the Jews ha imagination and theoretical insight. There is muc overlapping of course; we may find a Memlin among the Florentines.

It has occurred to me to wonder wherein lies th particular merit of the British. The pioneering spi of our illustrious forefathers is everywhere acclaimed and there is even now little sign of any decline in o initiative. Can it be at least partly the result of n working so hard that no time is left for reflexion We certainly defend our leisure from encroachmen with special tenacity. Again, it may be that we a in a certain sense undisciplined; but I will n elaborate that suggestion.

Science as a common international possession and th world-wide co-operation in its development must b bulwarks of peace. Here we have a realizable asset the greatest possible positive value. The brotherhoo of scientists is a reality. It is fortunately not unique there is a similar fraternity among sportsmen, musicians, chess-players, and other categories of enthusiast not encumbered by the so-called ideologies.

It should be clear from the definition that religion in so far as it is authoritarian and dogmatic, ca make no contribution to science. But it is no parado to say that there is room for both science and religio within the mind of a man. Indeed we have ampl proof that this is so from everyday experience. Man of the greatest of scientists have been deeply religiou men and eminent divines have been excellen scientists. Testimony to the help afforded to th Royal Society and to the British Association b churchmen may be found in the records and is stil apparent on inspection.

At the Bristol meeting of 1836 the presidents o Sections A, B, C and D were all clergymen.

On the other hand, many scientists have been, an are, free-thinkers. Yet, the two groups should b united in the unflinching pursuit of the truth and i a spirit of tolerance.

Titles such as "Science and Religion" tend t confuse the simple issue which relates to "Scientists" and not to "Science". Again, the uncertainties o modern physics are now considered by some to justif mystical analogies.

## Models and Pictures replaced by Equations

It would appear that there are many who feel a irresistible urge to fill up all gaps in knowledge b their own inventions. Such intuitive speculation ca indicate useful working hypotheses, but it is no science *per se*.

Actually physics is a much more complete an satisfactory system now than it was in the later nineteenth century. It is true that we are perplexed b many new problems; but at least we are aware tha they exist. That is an improvement on complacenc founded on ignorance. The human mind can b shown to be inadequate in several ways. Speakin subject to correction by philosophers, it would seem that certain alternatives that are logically mutuall clusive are equally inconceivable by us. The con- ptions of a continuum or a discontinuum, of creation indefinite projection of reality into the past, cannot grasped by the human mind. Yet the fact that find something to be incredible is no proof that does not exist. Hence physicists are content to rive expressions for the description of phenomena th the minimum of extraneous hypothesis.

Fifty years ago an ether was an article of faith ; ere could be no action at a distance without an tervening link, electromagnetic waves must occur something, and so on. But each invented ether as about as incredible as the absence of one. Nearly ty years ago I remember being fascinated by borne Reynolds's "Inversion of Ideas as to the ructure of the Universe". This postulated a very nse ether consisting of minute grains. Matter was negative inequality in this ether, that is, an absence grains, a kind of hole. It could be shown that the verse-square law would govern the attraction of ch holes. Mathematical physicists have evidently und it hard or impossible to use this theory, but I ell remember thinking more or less as follows : es, but what are the grains made of ? They have en invested with some of the properties of matter nd they are a kind of engineer's dream of perfect altonian atoms on a very small scale. The argument quite inconclusive ; but I found then, and have ways found since, that the idea of a continuum, en inside a grain of the ether was, and is, repugnant. nowadays we just arrange to do without this mfortable resource of an ether, though I have been ld that Prof. P. A. M. Dirac may revive the idea some form or another—which few of us will nderstand.

### Scientists' Duty to the State

Another feature of the complex make-up of the ientist is that he is a citizen and owes a duty to the ate. This leads to obvious conclusions in most spects. But where do we stand in regard to the vention of military weapons ?

In war-time few of us entertained any doubts out this ; it was our clear duty to help our country the best of our ability. Now it is a matter for the nscience of the individual, taking into consideration at we have not yet achieved a real peace.

The position is one of unstable equilibrium, and it still seems that as citizens we should do all in our power to strengthen the hands of our leaders, in whom we have placed our trust, and who we believe are sincere in their desire to achieve universal peace among the nations. Even the terrible nuclear-energy weapons must be developed by our scientists in peace-time so as to build up the necessary potential of deterrence, our only defence against extinction.

### Scientific, Technical and Technological Man-Power

I have mentioned only two or three of the personal problems of scientists ; but there are, as is very well known, many national questions affecting scientists, and on these I can say very little in this address. The chief is perhaps the training of scientists, which starts in the schools and involves the supply of science teachers. This matter has been raised in the General Committee of the British Association here in Bristol. We hope to make some small contribution to a solution of difficulties that are the cause of considerable justified anxiety among industrialists.

Finally, I want to say a word about technology and technologists. Dr. E. J. Holmyard and Prof. Charles Singer have, in the first volume of their monumental work on the "History of Technology", pointed out that it all started with handicraft. The modern technologist is still a man with 'know-how' and 'can-do', whether he be technician, craftsman, designer or supervisor, and he is equipped with knowledge of general and special scientific and engineering subjects.

It is generally agreed that we have far too few technologists in Britain, and that our economic survival is improbable unless we take some drastic steps to remedy the situation. The proposals that have been made are admirable so far as they go ; but, in the opinion of many who are well qualified to judge, they do not go nearly far enough.

It is doubtful whether any scheme tied to existing institutions can meet the requirements ; and to come right down to ground-level, I suggest that we need a 'Technology Grants Committee', independent of any other body and with power to expend a very considerable sum of money. This idea has probably already been adumbrated. In which case I think it should be supported.

---

# SUMMARIES OF ADDRESSES OF PRESIDENTS OF SECTIONS

## VACANT LATTICE SITES IN CRYSTALLINE SOLIDS

THE physics of the solid state is a wide field which ranges from abstract subjects rather mote from practical applications, such as super- nductivity, to problems of immediate technical portance such as the development of crystal valves nd the behaviour of the materials of a reactor under eavy bombardment by neutrons. In his presidential ldress to Section A (Mathematics and Physics), rof. N. F. Mott concentrates on one theme—the istence and behaviour of vacant lattice sites in ystalline solids—and shows its importance for a ide range of phenomena. A vacant lattice site is a oint in a crystal lattice from which the atom or olecule, which ought to be present in the crystal ructure concerned, is in fact absent. Vacant lattice sites occur in a crystal in thermodynamical equilibrium, some of the atoms having moved away as a result of the influence of heat motion. They can also be formed as a result of bombardment by fast particles and also by subjecting the metal to cold work.

The first importance of the concept of a vacant lattice site is its role in explaining the phenomenon of diffusion in solids and particularly in metals. When two metals are welded together and a region intermediate between them is formed which is occupied by an alloy of the two, diffusion has taken place. This means that two adjacent atoms in a crystalline solid are able to change places if the temperature is high enough. It is now believed that atoms change places only with the help of a vacant lattice site ; a simultaneous movement of two atoms would involve a very high energy and is improbable, but the loosening of a crystalline lattice near a vacant lattice site greatly lowers the energy necessary.

We are interested, therefore, in measurements of the number of vacant lattice sites in a solid and the rapidity with which they change places. One method of obtaining this information is by the use of radioactive tracers which enables the coefficient of self-diffusion to be determined. Another method which has come to the fore recently is by the use of the 'nuclear spin'—the magnetic moment carried by the nucleus of the atom concerned. When the substance is placed in a magnetic field, the existence of quantized stationary states associated with the nuclear spin in the field enables substances to absorb electromagnetic radiation of radio frequencies. The width of the absorption line depends on the extent to which each nucleus interacts with its neighbours and will vary from one nucleus to another according to the orientation of the magnetic moments of the adjacent nuclei. If, however, the atoms are changing places rapidly, this interaction between nuclei will be averaged out, and the breadth of the absorption line will be greatly decreased. In this way, it is possible to estimate the jump frequency.

Two methods, therefore, both borrowed from nuclear physics, are available for measuring the frequency with which atoms change places. The evidence that they change places with the help of vacancies comes from many sources, of which perhaps the most important is the fact that diffusion in solids is greatly accelerated after they have been bombarded by fast charged particles. It is thought that the vacancies produced by this bombardment remain in existence for a considerable time and, as they move about throughout the crystal, enable atoms to change places much more rapidly and at lower temperatures than would be possible without their presence. It is estimated that one fast neutron will displace as many as six thousand aluminium atoms before it is brought to rest, and one diffusion fragment in uranium as many as twenty-five thousand uranium atoms, so the effect need not be small. As a result of these displacements, the phenomenon known as radiation damage occurs in solids exposed to the radiations in a reactor. Mechanical strength, density and electrical resistance can all be affected. The subject of radiation damage is under active investigation at the present time, and there is still much which we do not understand about it.

Finally, it seems very likely that vacancies play a part in the phenomenon of metallic fatigue. As already mentioned, deformation or cold work is known to produce vacancies in a solid, with effects on its properties in many ways similar to those which result from nuclear bombardment. In fatigue one knows that localized regions of the solid, which show up as visible slip bands, are deformed plastically backwards and forwards many millions of times. Both experiment and modern theoretical concepts lead one to believe that in these regions very large numbers of displaced atoms are formed, so that after a time the crystalline structure of the molecule will be broken down as it would under intense bombardment. A detailed theoretical explanation of fatigue in terms of atomic movements has not yet been formulated; but one very possible view is that this break-up of the crystalline structure and consequent recrystallization would lead to intense local strains, and that it is these strains, perhaps accompanied by the effect of oxygen or other gases, which initiate a fatigue crack.

# NUCLEIC ACID STRUCTURE AND FUNCTION

SIR ALEXANDER TODD points out in h address to Section B. (Chemistry) that, althoug the nucleic acids rank with the proteins and carb hydrates as one of the three major groups of macr molecular substances of vital importance in livi matter, yet until recently they were the subject very little detailed chemical investigation. This ma have been due, in part, to the lack of suitable exper mental techniques for dealing with them, but it w also due to a surprising lack of chemical study of th simple nucleosides and nucleotides from which the are built up and which can be obtained from the by hydrolysis. All this is now changed, and we hav seen in recent years a veritable revolution which h led to a satisfactory formulation of the nucleic aci and a much clearer understanding of their chemic behaviour. This in turn has opened the way to fre advances in biochemical and biological studies whi have brought us closer to an understanding of the function.

Two types of nucleic acid occur in Nature—th ribonucleic acids and the deoxyribonucleic acid Graded hydrolysis of them yields first the nucleotide which are phosphates of the nucleosides, the latt being N-glycosides of certain purine and pyrimidi derivatives. The essential difference between th two types is that the sugar involved in the rib nucleosides is D-ribose, and in the deoxyribonucle sides, 2-deoxy-D-ribose. Both types of nucleic ac can be regarded as polynucleotides, the individu nucleotides being linked one to the other by phosph diester linkages. Based on detailed chemical studi which have clarified the structure and chemistry the nucleosides and nucleotides, a general theory the structure of nucleic acids as 3′ : 5′-linked pol nucleotides has been developed. All subsequent wo appears to confirm this theory, which has becom generally accepted. Synthetic work in the pol nucleotide field is still in its early stages; b dinucleotides of known structure have been sy thesized, and their properties are in accord with th general theory of nucleic acids. Further work is al needed in connexion with the determination of th sequence of nucleoside residues in individual nucle acids, since it is on this sequence that much of the biological specificity must depend.

Since the emergence of a clear structural pictu of the nucleic acids, much attention has been pa to their macromolecular conformation. In this fiel X-ray examination of deoxyribonucleic acids h been a fruitful source of information. According current views, deoxyribonucleic acids appear to exi in the form of two opposed helical polynucleoti chains wound together in a double helix and he together by specific hydrogen-bonding between th purine and pyrimidine bases occurring in ea nucleoside residue. This picture of deoxyribonucle acid existing in a double helical structure has mu in its favour and is now generally accepted in essentials. One of its most interesting features is th indication it gives of how a deoxyribonucleic ac may represent a self-duplicating system. This particularly important, since deoxyribonucleic aci are constituents of the chromosomes, and there evidence to suggest that in bacteria they are th actual genic material which determines heredita transmission. This concept of the nucleic acids replicating systems is also of great interest in co exion with viruses and bacteriophages, all of which ontain nucleoproteins. There has, too, been considerable speculation regarding the way in which ucleic acids may be involved in protein synthesis; is possible to suggest a mechanism for protein synthesis by means of nucleic acid, but no vidence is as yet available to show whether it has ny validity. Clearly, however, we are now at the pening of a new phase in the study of nucleic acid unction, and future developments are likely to have rofound repercussions in biology and medicine.

## GEOGRAPHICAL DISTRIBUTION OF PAST FLORAS

BIOGEOGRAPHY in relation to geological history was the starting-point of Darwin's evolutionary studies, and the opening sentence of the introduction to the "Origin of Species" reads: "When on board H.M.S. Beagle as naturalist I was much struck with certain facts in the distribution of the organic beings nhabiting South America, and in the geological relations of the present to the past inhabitants of that continent". Thus, in his address to Section C (Geology), Mr. W. N. Edwards shows that the biogeography of the past is still worth the attention of the student. Earth-movements and erosion, mountain building and climatic change are all reflected in the altered distribution of floras and faunas over the world, and the past distribution of animals and plants is often cited in support of the conclusions reached, or the theories put forward, by geologists and geophysicists. It is therefore well occasionally to review our knowledge of the relations between faunas and floras on one hand, and continents, seas and climates on the other.

Former land and sea areas can be roughly mapped by plotting occurrences of terrestrial and marine fossils, and geological evidence of past climates can be supplemented from the biological side. Land plants, in spite of arguments adduced to the contrary, are particularly valuable in this respect, especially if one considers ecological types of vegetation rather than individual plants. A review of fossil floras from the Devonian onwards in relation to known geological changes suggests that, although in the Devonian, and to a lesser degree in the Jurassic, world vegetation was fairly uniform, latitudinal zonation is more normal. The supposed uniformity of Jurassic floras is partly illusory, and there are in fact clear indications of zonation in that period; the early Devonian floras are not yet sufficiently well known ecologically for one to say whether they were so uniform as they appear to be. The plant evidence further indicates that since the late Palæozoic there have been vegetational and climatic zones parallel to the present equator. Deviations from exact parallelism, such as the arid belt running from eastern Asia across north Algeria, are due to the past conformation of the land masses of the northern hemisphere being similar to that of the present day. The vegetational succession in the northern hemisphere does not, therefore, lend support to notions of extensive wandering of either continents or poles, at any rate since the Carboniferous. Following the orogeny and glaciation of the upper Carboniferous and Permian, the major influences on plant distribution in the Old World have been the arid belt just mentioned and the Tethys Sea. The latter, which was in existence from the upper Palæozoic to the middle of the Tertiary, must have formed an important migration route for plants, not only along its shores but also by marine currents. Transmarine distribution of land plants would have been particularly easy in a sea which ran for some six thousand miles from east to west in an equable climatic belt of much the same character throughout. Angiosperms may possibly have arisen in the Indo-Malayan region and spread first along the Tethys Sea.

## IMMUNITY AND DEVELOPMENT

THE borderland between immunology and embryology, which forms the subject of the presidential address by Prof. F. W. Rogers Brambell to Section D (Zoology), has proved a fruitful field of research in recent years. The relationship of mother and young in mammals involves special immunological problems, for reactions resulting from immunological incompatibility can cause severe damage or death of the fœtuses, perhaps of the mother also. An adult mammal responds immunologically to the introduction into its system of tissues, cells or proteins from another species, or even from another individual of the same species. These reactions are an expression of the individuality of the adult organism.

The capacity to respond immunologically to the introduction of antigens into the system by the production of circulating antibodies appears relatively late in development. Circulating antibodies cannot be produced in detectable amounts by active immunization of new-born animals. The mammalian fœtus and the chick embryo can tolerate exchange of blood-forming cells of different blood group from a non-identical twin, and become permanent blood-group chimæras. Grafts, even of mammalian tissues, can be grown on the chorio-allantoic membrane of the chick embryo, without apparent reaction.

At a still earlier stage of development, the zygote nucleus comes into being in an environment of maternal protein. The cytoplasm of the egg must contain maternal proteins that would be antigenic in the adult offspring, yet it is in this medium that the zygote nucleus must function and initiate the synthesis of all those proteins which will characterize the new organism. Hence the fœtus and the young animal are tolerant of foreign proteins, cells and tissues to which they would react immunologically when adult. This immunological inactivity obviates the risk of the fœtus reacting to incompatible maternal antigens during pregnancy, but leaves it unable to protect itself against infection at birth. Temporary protection is afforded by the passive transference of antibodies from the mother.

These considerations lead to a discussion of the route by which passive immunity is transferred from mother to young, of hæmolytic disease of the new-born, of the selective passage of proteins through the entoderm and of experimental induction of tolerance to antigens. Most of the topics concern recent work which appears to advance both mammalian embryology and immunity. These studies have thrown new light on the functions of the fœtal membranes in mammals and on the causes of much pre-natal and neo-natal mortality. They have shown that the cells of the fœtal membranes can selectively transport globulin according to the species in which it was synthesized. This selectivity has some resemblance to other known immune responses, such as passive anaphylactic sensitization of smooth muscle; but the mechanism by which it is effected remains to be elucidated. It is exercised at a much earlier stage of development than that at which the organism can produce circulating antibodies. Likewise, in actively acquired tolerance, we have evidence of the embryonic cells being permanently modified by exposure to specific antigens at a stage long before they are capable of reacting by the production of antibodies. Why exposure of embryonic cells to antigen should inhibit the subsequent formation of the specific antibody by these cells, whereas exposure for the first time of adult cells to the same antigen induces the formation of the specific antibody, is another problem that awaits solution. The solution of these problems may be expected to give us a glimpse, at least, of the fundamental cell processes involved in the fabrication of specific proteins. All these phenomena may depend on the 'recognition' of the molecular form of proteins by the cells, a property which might prove to be of wide significance in embryonic differentiation.

Immunological methods open the way for experimental approaches to problems of vertebrate embryology that hold promise of great advances in our understanding of the development of function—of physiogenesis rather than morphogenesis.

## GEOGRAPHY AND ITS HISTORY

THE history of geography has never before been the subject of a presidential address to Section E (Geography); Mr. J. N. L. Baker's address to the Section this year deals exclusively with geography between 1500 and the beginning of the nineteenth century, and is especially appropriate to the city of Bristol, with its connexions with Robert Thorne the younger, Richard Hakluyt, and the merchants of Bristol who searched for the island of Brazil. He points out that the history of geography is a subject that can be approached only with the help of the work of many scholars, including Dr. R. Hartshorne, Mr. G. R. Crone, Dr. J. A. Williamson, Dr. O. J. R. Howarth and, above all, of Prof. Eva Taylor.

The growth of academic geography in Britain has been one of the remarkable facts of the past fifty years; but those who speak of the 'new' geography would do well to consider the present position of the subject, in H. R. Mill's words to Section E in 1901, as "the outcome of the thought and labours of an unbroken chain of workers". The nineteenth-century 'new plans' for geography of Pinkerton and Malte-Brun, like those of Busche and Busching of the century before, drew heavily upon older works. Geographers throughout the past four centuries, at least, have always been dealing with 'the old imperfectly composed' and 'the new lately reformed'. Geography is a subject that is always alive: without that life it is nothing.

In the past, geography has been regarded as an essential part of general education. John Milton, John Locke, Samuel Johnson and Edward Gibbon all showed clearly their appreciation of geography as part of the culture of an educated man, and the works of Bodin, Rousseau, Buffon, de Brosse and others in France suggest that the position was similar there in the seventeenth and eighteenth centuries. In the writings of the period it was assumed that readers would appreciate geographical references: many of Milton's lines, for example, mean little or nothing without a knowledge o geography as understood in his day.

The ability of geography to help in practica affairs is no new feature of the subject. It has alway had a practical side, both in the narrow sense throug its contributions to exploration and navigation and in a wider manner, through its close connexion with classical studies. Annotated editions of the works o classical geographers, and bulky geographical dictionaries, were common and indicate the status o the subject. If modern geographers can make similar contributions to the general culture of our age, they will, in that way alone, justify their existence.

Although for long periods there has been geography, for equally long periods there have been no geographers in the technical sense of the word. There was no accepted meaning for the term 'cosmography', which was replaced by 'geography' in the eighteenth century. Furthermore, geography was not confined to those who wrote cosmographies and geographies. The conclusion is clear that there have been many kinds of geography and many writers of geography, so that present-day geographers should be modest and circumspect in their claims. No geographer need apologize for, or be ashamed of, his subject, with its long and honourable history that offers almost unlimited scope for research. The rewards of such research will be great, because it is only when the geography of our day is seen against the background of its history that its present position can be appreciated and its future prospects assessed.

## THE ENGINEER AND MARINE TRANSPORT

IN his address to Section G (Engineering) on "The Influence of the Engineer on Sea Transport and Trade", Dr. S. F. Dorey points out that during the latter part of the eighteenth century warfare and monopolies were responsible for the British attitude of complacency towards overseas trade and commerce. The lack of competition resulted in stagnation of the design and development of merchant ships. The Americans, however, on achieving political independence, exploited the merits of cheap, fast sailing-ships and captured the bulk of the trade and traffic on the Atlantic and Pacific. Moreover, the progress they made in the design and development of the clippers gave them an almost unsurpassable lead in sail, and it was due entirely to pioneering the steamer that the British were able to offset the advantage gained by the Americans. During the 1830's, steamers commenced a trans-Atlantic service; but their use on longer sea-routes was impeded by the high coal consumption of the machinery. It was not until the 1860's, when the more economical compound engine was introduced, that impetus was given for the expansion of trade to the Pacific.

At about the same time processes for the quantity production of cheap mild steels were evolved, and construction of ships and machinery of mild steel gave rise to greatly improved performance and reliability. Economy of coal consumption improved again with the adoption of the triple-expansion steam engine and enabled steamships to open up trade with the Far East. The development of the liner demanded machinery of high power; but steam reciprocating engines proved unsuitable where more than 40,000 I.H.P. was required for a single ship. The solution this problem was provided by Charles Parsons at e end of the nineteenth century. His steam-turbine wer plants enabled machinery of 70,000 S.H.P. to installed in a liner in 1907, and the service coal nsumption was nearly one-half that of the equilent reciprocating machinery.

Following the First World War, when competition s keen to secure freights, the engineer played his rt in reducing the operating costs of merchant ips. The increased use of oil-firing, the remarkable velopment of the oil engine, and greatly improved iler and steam-engine designs may all be cited. hen trade eased, the drive for still further economy s maintained, and at the same time the power tputs of machinery were increased to meet parular needs. During recent years particular attenn has been given to the machinery of large single-ew tankers and ore-carriers which handle the w materials of the expanding oil, chemical and tallurgical industries. The new types of prime overs are also receiving consideration. The marine s-turbine is still in the development stage and has t reached the degree of long-service reliability and w fuel-consumption enjoyed by the other two main pes of prime movers.

The marine application of atomic energy offers eat attractions, particularly so far as weight and orage of fuel is concerned, but will only become asible by reducing to attractive levels the weight, e and cost of reactors and screening, and the tisfactory solution of control and maintenance oblems. Auxiliary shipboard machinery has also ayed a prominent part in establishing new trades. e introduction of refrigerating machinery, for ample, opened up the meat and farm-produce trade d brought prosperity to Australia, New Zealand d South America. The achievements of marine gineers have had considerable influence on the osperity of nations and, with the aim of improving r living standard still further, the engineer will no ubt continue to play his part, as evidenced by the gh rate of progress maintained during the post-war ars.

## ANTHROPOLOGY—A SCIENTIFIC UNITY ?

DR. D. B. HARDEN, in his address to Section H (Anthropology), comes to the conclusion that the estion whether anthropology is or is not a scientific ity is one that, after careful thought, can only be swered in the affirmative. He has, he says, never en answered in any other way by those who have ken part in developing anthropological studies thin the British Association from its earliest years, is clear by even a cursory glance at the historical owth of the subject up to the time when it attained tional status in 1884 and in the years beyond.

Up to 1846 anthropology, or ethnology as it was en usually called, only appeared sporadically in the sociation's programmes—usually in the Zoology or ology Sections. In that year Section C (Geology d Geography) formed a sub-section for ethnology, d in 1851, when geography became a separate ction (E), it carried ethnology with it. The next ange was in 1869, when anthropology became one of veral departments within Section D (Biology). The nological side of Section E was then abandoned d the Geology Section ceased to carry papers on man palæontology (as it had done from time to time hitherto). This arrangement lasted until 1884, when anthropology was promoted to full sectional status as Section H.

Since then the Section, both in its annual programmes and through its research committees, has spread its net fully and widely over the whole field of anthropology—the study of man in the past and in the present. Its programmes have embodied prehistoric and historic archæology (both British and foreign), physical and social anthropology, ethnology (both of primitive and advanced cultures), folk-lore and comparative religion. The Section's interests are, indeed, broad—as broad as, if not broader than, those of any other Section. So broad are they that it is impossible for them all to be properly represented in the programme every year ; and the more specialist-minded of anthropologists, ethnologists and archæologists are inclined to complain of this and to say that it is no longer worth their while to come to the meetings unless the Section is split into two or more parts, so that more papers in their own special subjects can be fitted in. This, Dr. Harden maintains, is a misguided view, for the British Association has always endeavoured to be a widely ranging body, and its objects would be defeated if one of its Sections became just another specialist conference.

Anthropology touches on so many other sciences and disciplines that there is no one sectional activity within the Association with which it does not have mutual contact at one time or another, as its previous alliances with geology, geography and biology make plain. Anthropology, the study of the human race, is, indeed, by its very nature a microcosm of the Association as a whole ; properly used, the Section programme could be a unifying influence within the Association. Dr. Harden maintains that this aim cannot be achieved by trying to plan programmes which will attract and satisfy diehard specialists in even some, let alone all, of the various branches of the subject, for this will interest neither the specialist nor the more broad-minded student. He proposes that advantage be taken of the existence of other Sections in the British Association to arrange programmes which will show the overlap between them and Section H, and that members of Section H should at the same time hold fast to their unity and pay no attention to any pressure from the partitionists. To accept such pressure, he concludes, and thus encourage specialization, will do disservice not only to anthropology as a unified scientific discipline but also to the Association's own interests and policies.

## THE SENSORY PATHWAY

THE pathway from receptor to brain is in all cases built up on much the same pattern and involves a series of interruptions or relay stations where the message is transferred to a new set of nerve cells. The theme of Dr. R. S. Creed's presidential address to Section I (Physiology) is the significance of these breaks in continuity on the way to the sensorium. What is the reason for their existence ? Why is there not a direct route for through traffic ? Satisfactory answers to these questions cannot be given by simply comparing the nervous system with a network of telephone lines and the relay stations in grey matter with telephone exchanges. As is known from studies of reflex action, much more may happen at synapses between nerve cells or their processes than mere shunting of excitation along certain channels. Inhibition, facilitation and after-discharge may be expected to occur in the sensory, just as they do in the reflex, pathway.

Until recently, it was necessary to rely mainly on subjective human experience in work on the physiology of the senses. Now, as a result of improved electro-physiological methods introduced by Adrian, it is possible to make objective records of events in single units at various levels in the ascending sensory pathway. Such studies not only provide a valuable check on what can otherwise be only rather indirectly inferred, but also give definite information about the anatomical site at which modification of messages occurs. There is still much scope for further advance of knowledge by both subjective and objective methods.

In skin, ear and eye, it is certain that there is considerable overlap in the area of distribution of individual afferent nerve fibres. This has sometimes been thought to raise theoretical difficulties about the neurological basis of localization of stimuli. It is argued that these difficulties are largely illusory and that overlap may actually facilitate accurate identification of the site of stimulation.

The number of receptors is commonly much greater than the number of nerve fibres ascending to the sensorium. This forms the basis for the areal facilitation or summation which is so obvious a feature of natural stimulation of skin and retina. It also, however, provides opportunity for activity in one pathway to inhibit simultaneous activity in neighbouring pathways. There is evidence that this occurs in cutaneous, visual and auditory relay stations.

More puzzling is the multiplication of pathways for which, after preliminary convergence, there is good anatomical evidence in the senses of smell, vision and hearing. Although the sensorium, as analyser, clearly cannot manufacture detail out of material which is undetailed at lower levels, speculative suggestions are made about the possible avoidance of blurring which may result from such divergence.

Finally, the pathways from the two great paired sense-organs of sight and hearing are compared and contrasted. Physiological evidence indicates that in the former there is almost no confluence of the twin pathways from the two eyes even at the highest levels. In the latter, summation occurs to such an extent that a sound heard with both ears has the same apparent loudness as one of double its physical intensity heard with a single ear.

---

## THE EFFECTIVE USE OF MAN-POWER

IN his presidential address to Section J (Psychology), Mr. Alec Rodger discusses the effective use of man-power. He speaks as an occupational psychologist, as a scientist and technologist concerned with the discovery and use of knowledge about people as workers of every kind and level. The knowledge the occupational psychologist is specially interested in is knowledge about determinants of behaviour conveniently regarded as (*a*) individual and internal, but (*b*) 'left over' when the physiologist has done all the explaining he can manage. It is useful to call these, broadly, capacities and inclinations. The psychologist's task in his occupational specialization is to put our thinking about them on a soun theoretical basis and to bring it to bear, in a skilft fashion, on the problem of 'fitting the man to th job' (through improvements in methods of vocationa guidance; personnel selection; and occupationa training) and the complementary problem of 'fittin the job to the man' (through improvements i methods and organization of work; equipmen design; and working conditions of diverse kinds).

Before reviewing urgent tasks in these fields o interest, Mr. Rodger stresses the importance o recognizing their essential unity. It is unfortunate he says, that psychologists dealing with one type o problem sometimes display little appreciation o thoroughly-relevant work being done by their colleagues. For example, investigators concerned mainl with fitting the job to the man are inclined to assum that all men are equal, or nearly so, in their capacitie They are therefore apt to overlook individual differences found to be crucial by investigators concerne chiefly with fitting the man to the job. This leads t misjudgment of the importance of the nature an size of the population samples used in thei investigations, and to unwise expenditure o precious research funds on projects too narrowl conceived.

In the field of vocational guidance, where plannin for the effective use of man-power should begin, th most pressing need is for long-term studies designe to reveal, by the application of appropriate criteria the strong and weak points of currently used concept and methods. On such studies will depend th solution of many major problems, including the mos fundamental of all, that of classifying occupation for vocational guidance purposes. What is particularly required is a series of integrated studies of th differentiating capacities and inclinations of successes and relative failures in a variety of occupation This notion is equally applicable to the study o certain personnel selection problems, including som arising in the management field. In the field o occupational training, consideration of individua differences in capacity and inclination may well lea to a radical overhaul of existing arrangements i Britain, not least of the apprenticeship system, whic is archaic and wasteful.

Mr. Rodger, outlining some of the tasks awaitin the occupational psychologist in the field of method and organization of work—the field of 'work-study'— suggests that the nature and extent of the arbitrar judgments involved in time-study urgently requir investigation. Until we know more about the answer to certain questions that arise here, we shall b entitled to wonder whether a good deal of time-stud is not a piece of mumbo-jumbo developed—by agreement between management and workers—to provid an apparently rational basis for the payment o wages the amount of which has already been settle by quite other means. Touching on problems o equipment design, Mr. Rodger thinks it is time w began to take serious account of the fact that automation tends to produce a proportionately highe demand for skilled than for unskilled workers. H concludes by arguing that in the study of all th main factors to be considered in the shaping of wage differentials—skill, effort, responsibility, dirt an danger, to use Mr. Hugh Gaitskell's list—the occupational psychologist should have a contribution t make; for all these demand the investigation of problems of capacity and inclination, which are th occupational psychologist's meat and drink.

# BIOLOGICAL ORGANIZATION

THE biologist is faced with many different but interdependent levels of organization in the stems which are his concern—systems which range om the smallest living particles, like genes and ruses, to the large aggregates denoted as populations d communities, including human society. In his ldress to Section K (Botany), Prof. K. Mather oints out that genetics and cytology have shown us ow the nucleus is organized for the perpetuation d recombination of the hereditary materials. They e beginning to show us, too, how the gene is ganized as a unit of action depending for its aracteristic mediation of a complex biosynthetic rocess on the arrangement of its parts in a special atial pattern. The remainder of the cell, conentionally covered by the title of cytoplasm, is an ggregate of materials, processes and even systems, e properties, origins and maintenance of which e extremely varied. The mitochondria may ell provide a mechanical basis for at least part the cytoplasmic organizations; but balanced ction here must depend more on chemical uilibration than mechanical control as it does in e nucleus.

The nucleus provides the firm foundation on which toplasmic balance can be built; but the cytoplasm an react back on to the nucleus, as indeed we see in ngal heterokaryons, where the genic balance is djusted by cytoplasmic alterations of nuclear ivision. Nucleus and cytoplasm are thus complementary and inseparable in cellular organization, ne securing the constancy needed for control and e other the flexibility needed for adjusted action. somatic differentiation this adjustment is related etween the cells, some differences being built up nd others suppressed to give the characteristic atterns of development. Its success depends on the bility of a constant nucleus to stimulate and manage changing cytoplasm.

Each cell is at once a complex organization in self and a specialized part of the higher organization hich we term an individual. Individuals in their urn are parts of the organizations which we term opulations, within which they are tied together by unctional relations in reproduction (as in dioecy, eterostyly, etc.), protection, survival or the maintenance of genic balance. Being functional, hese bonds may tie together as collaborators n one function individuals which are complete nd therefore competing units in respect of ther functions. Individuals of different species may be tied functionally in symbiotic organizations.

All organization, at its many different levels, epends for its origin and survival on the efficient ivision of labour among the parts (which may themselves be organizations at another level) in the disharge of some function. These parts may be bound ogether temporarily or permanently by a wide ariety of means—morphological, physiological and ehaviouristic. Any organization must have the roperty of continuation or recurrence; this is secured at the genic and nuclear levels by reproduction as wholes, the daughter being already a eplica when it parts from its mother, and full ontinuity being thereby secured from the start. ome parts of the cytoplasm secure their own eproduction in the same way, but others are uilt up only in certain circumstances, so giving the characteristic versatility and capacity for change. The repeatability of pattern in this change is governed by the continuous organs of the cell, especially the nucleus. Some continuing parts of the cell may, however, have entered it initially by infection, depending for perpetuation on their own heredity, now part of that of the cell.

The cellular organization of nucleus and cytoplasm provides the basis necessary for somatic differentiation, nuclear control having developed in such a way as to replace opportunistic responses by ordered changes of the cytoplasm in large measure divorced from the immediate external environment. The organization of populations and the differentiation of individuals within them similarly depend in the general case on the nucleus, which often here has the added function of switching development into its different individual paths by genic segregation. Populations differ from somata, however, in that they may be propagated characteristically by a gradual replacement of parts, so that new members may be adjusted by the action of old ones, as is, for example, the case where some process of learning is involved. In symbiosis each component must depend on its own genetic balance for continuing adjustment, but this must be governed by relations external rather than internal to the individual nucleus. The symbionts must also be endowed with some means of securing their co-ordinated distribution in propagation. This may be secured by the activity of one partner in carrying the other with it, but other means may well also be possible. The mutual adjustments of symbionts, especially their genetical adjustments, offer an important and virtually untouched field of investigation.

No organization is immutable. Changes are continually occurring in the controlling genes. The alterations are mostly degradatory and are weeded out by selection, which may result either from the direct competition of other units of organization at the same level—for example, of cell with cell—or from the failure in competition of a higher organization because of the deficiency of its parts—for example, the failure of an individual because of maladjustment of its cells. Occasionally, however, change will lead to a more efficient organization which will then be at an advantage in selection. Genetical evidence is unanimous that all the complexity of biological organization and its control has arisen in this Darwinian fashion.

Human society differs from most biological organizations in that continuity and control have come to depend on education (in the broadest sense) rather than heredity, though the underlying genetical requirement is still there. This process of education resembles infection rather than heredity in its properties and offers new opportunities while posing new problems. The controlling laws, customs and so on are subject to change, and have undoubtedly evolved in the competition of individuals, communities and societies in the past. The character of this selection is, however, no longer like that of biological levels, and we are seeking to control it. In doing so, we must not forget that our society is but another level of organization superimposed on all the biological systems below it. To flout the principles common to them all and to shut our eyes to their interactions could lead only to disaster.

## THE EDUCATED MAN IN 1955

EACH age and civilization has its appropriate pattern of education, some emphasizing the conservative element, others the forward-looking. In his presidential address to Section L (Education), Mr. J. F. Wolfenden asks if there is, in Britain in 1955, such a pattern discernible, with its attendant type of 'educated man'.

Some hold that the prime distinguishing mark of the educated man is his understanding of human nature, on the ground that the most important fact about this planet is that human beings, each a unique blending of spatio-temporal body with eternal spirit, live on it. The corresponding educational pattern is composed of literature, history, philosophy, economics ; it is not remote or 'literary' if it is fertilized by daily contact with practical human affairs.

This picture appears to leave out non-human phenomena, the subject-matter of natural science. The study of natural science begins as a disinterested inquiry. Nobody in 1955 can ignore scientific thinking and its consequences.

Many people brought up in the 'humanist' tradition not only do not know many scientific facts which are important ; but also, more fundamentally, are incapable of certain modes of thinking derived from scientific studies and indispensable to an understanding of affairs in 1955. This does not mean that the scientist is automatically a more educated man than the non-scientist ; he may be illiterate, incapable of historical imagination or of human insight. But it does mean that there are people who are scientifically illiterate. Nor does it mean that the scientist is the man who should decide politics—local, national or international. That is a misunderstanding of the nature of his training and his skills, especially as he must often, for the purpose of his own studies, ignore human factors.

So far we have been concerned with what will always be the education of a minority. The most important revolution ever to occur in educational theory and practice is the national decision that other forms of education in Britain besides that of the 'grammar-school' type shall be recognized as secondary education. To think in terms of educating everybody is revolutionary. Is there a type of education, based on this view, which will lead to a new kind of 'educated man' ?

To be called educated a person must be able (*a*) to appreciate the achievements of the human race ; (*b*) to move with some facility in the realm of abstract ideas. These criteria cannot at present be satisfied by the 'secondary modern' type of person or of education. This assertion is not undemocratic (though it is un-egalitarian) because the essence of democracy in education is not to provide the same thing for all but to provide the right thing for each.

It may be that there will arise an un-aristocratic culture, based on a new kind of approach to human affairs ; and it may be that a new form of conceptual thinking will emerge, superseding the verbal. But it is hard to believe that this will ever be within the capacity of the majority.

## THE IMPACT OF EDUCATION ON FARMING

IN his presidential address to Section M (Agriculture), Mr. W. B. Mercer points out that agricultural education in Britain grew up during the years of depression at the close of the nineteenth century ; b little progress was made until the Development Fu Act of 1910 made appropriate monies available. T general scheme then devised divided the field in three sections : formal education, research a advisory work among practising farmers. Apart fro such advisory work as the universities and colleg could continue to carry out, the main task of inte preting research and carrying its fruits to the farme fell on the county councils—and at a later stage the National Agricultural Advisory Service.

The scheme has evolved broadly on the lines the laid down, but has been profoundly influenced commercial firms providing agricultural requisite by public corporations such as that for sugar bee and marketing boards ; even more has it bee influenced by State direction and price guarantee which have permitted pioneer farmers to adventu boldly in the development of new techniques. Tec nical progress is very closely linked with commerci prosperity. Though we have never squarely face the problem of optimum agricultural production an man-power, we have always paid at least lip servic to the idea of good husbandry and high output, an our policy in Britain to-day aims at steady expansio of production with a probably declining labour force Thanks to the manner in which advisory forces ar organized and to the many influences which can b brought to bear on any selected theme, it is no possible to mould or modify farm practice at a pac hitherto undreamed of.

Educational work started with soil science an plant nutrition ; animal nutrition came later ; only within recent years have the arts of animal and farm management, the latter with its attendant problem of finance, been subjected to scientific study. Th influence of agricultural education on the severa enterprises which make up modern farming ha therefore varied greatly. Nevertheless, in mos sections of the industry the links in the chain o research — interpretation, exploitation, absorptio into practice—can be traced fairly clearly.

The study of grass as a crop has proceeded fro the early work on hay at Rothamsted and the Cockl Park trials with grazing sheep, the results of whic at first appeared contradictory. It was many year before the real difference between a hay field and pasture with its clovers was appreciated, and severa decades before the value of the grass leaf as distinc from the whole plant was demonstrated. Once thi was grasped, the way was open to intensive gras production, to a study of interactions between cro and animal and to the evolution of an entirely new outlook on grass and entirely new systems of stock management.

In the widely different field of hygienic milk production, the role of the researcher has been technicall much simpler. Here the main problem has bee creation of an attitude of mind among producer rather than projection of a stream of new discoverie

Poultry keeping forms a curious outlier to th general current of evolution. That developed from hobby and a part insurance against unemploymen into an industry mainly by trial-and-error method exploited by practical men, and only when this stag was reached was scientific aid brought in. Commercia poultry keeping to-day is based on Mendelia breeding.

Many different lines of work converge in problem of land and stock management, and experimenta work becomes, therefore, very complex. It is a mos opeful sign of the times that so many men in farming e prepared to undertake the onerous tasks of anagement which intensive production involves.

---

## THE FRAGMENTATION OF SCIENCE

N his presidential address to Section X (Assembly of Corresponding Societies), Mr. Ritchie Calder oints out that, by the excess of specialization forced pon them by the rapid advance of research and the ast literature of their subjects, scientists are using nly a part of their faculties and allowing the others o languish. They are becoming intellectual cripples. hey are so busy synthesizing Nature that they have o time to synthesize their own science.

Present-day science, by its emphasis on experiental research, has forsaken natural philosophy, nd in its hurried retreat from scholasticism is orgetting the scholarliness in which it made ommon-ground with the humanities. Over-specialzation gives the scientist the excuse for saying "We have no time for other subjects", and their olleagues in the arts the excuse for saying "How an we understand ?". The fragmentation into more nd more branches, each with its jargon, is dividing cientists from each other and from the wider public. his separation from the wider community is fraught ith danger for our civilization and for science itself. cience, which exists to remove mystery and magic, s creating its own mysteries and magic. People egard science with a kind of superstitious awe, but ount on it for the gadgets. In the absence of proper nderstanding of the methods and processes of cience and of any social integration, the apparent haphazardness of discovery encourages a popular attitude towards science which is distrustful and unhealthy.

The educational system of Britain has become lopsided. Our schools and universities, by too early and continuing segregation, give too little science to one section of citizens and too much to another. This is as much a criticism of the humanities as it is of the science faculties.

The public has an uneasy awareness that the branches of science are out of step. On such an issue of life or death as the hydrogen bomb, it is realized that the physicists have outstripped the biologists—with the sombre risks which Lord Adrian forebode. Prof. A. V. Hill had also stressed the risks of medical science outstripping the means to feed the lives that are saved.

It is suggested that the proposal put forward in the British Association report on Post-War University Education (*Advancement of Science*, 3, No. 9) be re-examined—that there should be honours and pass schools of "Philosophy, Natural and Social" and that this should be reflected in the schools as general instruction on "scientific methods and social implications of science" ; that experts—doctors, engineers, agronomists, etc.—going into the widening fields of mutual aid should temper their expertize by some training in social anthropology, and that we would do well to revive, even at this late date, Comenius' idea of *Pansophicon* (1641), to bring scientists together to assess and explore all natural knowledge and propound it and make it widely known for the adoption by men for their benefit. Then, perhaps, we could get that synthesis of scientific knowledge by which science and humanity could progress together and science become wisdom.

---

## NEWS and VIEWS

(*Continued from p. 432*).

plants, as would be expected because of their inherent metabolic differences and the variations in their physiological states induced by experimental conditions. Sucrose became radioactive in very different amounts in two major groups of plants, namely, those containing only photosynthetic tissue, and those containing non-photosynthetic tissue as well. The amount of radioactive sucrose in the former group was much lower than that in the latter. An unidentified compound became radioactive in appreciable amounts in two of the blue-green algæ, but was radioactive in very small amounts, or not visible at all, on the chromatograms of all other plants.

### Changes In Lunar Topography

In a second paper on changes observed on the surface of the moon, Dr. H. P. Wilkins deals with "Bubbles and Streaks" (*J. Brit. Interplanetary Soc.*, 14, 3; May–June 1955). In collaboration with Patrick Moore, Wilkinson has recently investigated a number of rounded hills or 'domes' and has listed about a hundred, most of which have diameters of two to three miles and heights of a few hundred feet. A very remarkable thing about these domes is that they generally have a deep pit at the top, the pits being seated centrally, never at the side; it is extremely improbable that they could have been caused by meteorites, which would strike the sides also, but there are no signs of this. As very few of these domes were found until recently, the conclusion is that the older observers were not as careful in their work as is generally supposed, or, alternatively, they have been recently formed. If the latter hypothesis is adopted, the most likely explanation is that some volcanic activity still remains on the moon, the slow welling out of the magma forming the dome, and the pit at the top representing the vent. One very remarkable piece of evidence tending to confirm this view is the fact that domes now stand on some of the sites where older observers announced depressions. It is suggested that local swellings of the surface may occur in places and that the resulting domes are cavernous. Dealing next with the streaks, Wilkins points out that these were almost entirely overlooked by the older observers; and while admitting that they may be due to faulting or the formation of narrow cracks, he suggests that they may be due to some low form of life, such as lichens or fungus. This suggestion was actually made many years ago by W. H. Pickering, who thought patches in the crater Eratosthenes seemed to move about and to choose their paths in an unpredictable manner. Although Pickering's views were not generally accepted, they are difficult to disprove—even if they are equally difficult to prove; no instrumental equipment at present could definitely disprove the theory of some low form of life on the moon.

## High Altitude Research: Symposium in Gulmarg, Kashmir

At the meeting of the Council of the National Institute of Sciences of India, held in New Delhi in October last, it was decided to organize a symposium on "High Altitude Research" during May 27–28, at the Gulmarg Research Observatory, Kashmir (director, Prof. P. S. Gill). Gulmarg Observatory was selected because of its unique position. Situated at a height of 9,000 ft. above sea-level, it compares favourably with several outstanding high-altitude laboratories elsewhere in the world. The site is also suitable as a base station for work at still higher altitudes up to 11,000 ft. at Khillan Marg, one hour distant, and up to 14,000 ft. at Apharvat, three hours distant. The geomagnetic latitude (23° 32′ N.) and longitude (75° E.) are of special significance in cosmic-ray measurement, for the latitude is that at which the most rapid cosmic-ray changes occur with changing latitude, and the longitude is close to that where maximum effects of the Earth's magnetic field are observed. The symposium proper was held on May 28, the morning session being allotted to biological sciences, and the evening to physical sciences; but the boundary between the two sciences was never very sharp. In all, about seventy papers were read, and the proceedings will be published in the form of a bulletin by the National Institute of Sciences of India.

## Science Students in New Zealand

The Department of Scientific and Industrial Research of New Zealand has carried out a most valuable survey into the supply, quality and employment of graduates in the various scientific disciplines in New Zealand. Included in the survey were 4,852 students (4,068 men and 784 women) who had begun university courses in science since 1950 (New Zealand: Department of Scientific and Industrial Research. Bulletin 113: The Academic Record of Science Students in the University of New Zealand. By I. D. Dick, R. M. Williams and Dermot Straker. Pp. 64. (Wellington: Government Printer, 1955.) 6s. 6d.). Among the information collected was the length of study, the subjects studied and the marks obtained, the kind of degrees taken and the time taken to get them. A broad picture of the employment followed by the science graduates showed that about one-ninth went into the Department of Scientific and Industrial Research, one-ninth into school-teaching, one-twelfth went overseas and one-thirteenth went into industry. Those who joined the staff of the University of New Zealand were of high academic quality, as were those who went overseas; school teaching attracted few with first-class honours degrees.

## Sodium in Empty Ether Bottles

Mr. D. Rainy Brown, of J. F. Macfarlan and Co., Ltd., 8 Elstree Way, Boreham Wood, Herts, writes stating that bottles which have contained ether are returned to the firm from time to time containing traces of metallic sodium, presumably used to remove traces of water. There is a real risk of fire when such bottles are washed. Although precautions are take Messrs. Macfarlan have over a period of years ha accidents, although fortunately none of them we serious. They therefore ask those who use sodiu for drying ether to have special vessels for th purpose, or to ensure that no sodium is left i returned bottles.

## Petroleum Films Bureau

The 1955 edition of the list of 35-mm. and 16-mm documentary and instructional films issued by th Petroleum Films Bureau contains no fewer tha forty-five additions to the previous catalogue. Amon the new subjects available are "Ageless Iraq"; "Th Search for Oil"; "Assam Oil Survey"; "The Digbo Story"; "The Chemistry of Oil"; "The Modern O Refinery"; "Red Ruin" or prevention of rust "Individual Aircraft Series", including the Comet Valiant, Brabazon and Hawker Hunter. All 16-mm films are 'non-flam' stock; 35-mm. films are 'flam stock. Applications from educational establishment scientific and technical societies, youth clubs an the like to borrow films should be made to th Petroleum Films Bureau, 29 New Bond Street London, W.1.

## University of Liverpool

The following appointments in the University o Liverpool have been announced: Dr. J. D. Cragg reader in electronic engineering, to the Robert Rankin chair of electronic engineering; Mr. D. L. Hughes head of the Veterinary Science Division, Boots Pur Drug Co., Ltd., Nottingham, to the chair of veterinar pathology, in succession to Prof. R. E. Glover, wh has become head of the Royal Veterinary College London; Dr. F. D. S. Butement, a principal scientifi officer at the Atomic Energy Research Establishment Harwell, to the newly established post of senio lecturer in radiochemistry in the Department o Inorganic and Physical Chemistry.

## Announcements

The autumn conference of the British Occupationa Hygiene Society will be held at the London School of Hygiene and Tropical Medicine on November 4 the subject will be "The Use and Abuse of Protective Equipment". Further information can b obtained from the Honorary Editor of the Society Dr. C. N. Davies, London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1.

It has been the practice for some years past fo members of the atomic energy projects of the three countries, the United Kingdom, the United States and Canada, to meet to discuss problems of common interest in the field of health and safety. It is proposed to hold another of these meetings at the Atomic Energy Research Establishment, Harwell, on September 19 and 20, specifically to consider programmes of genetic research. In certain quarters this has been reported as an international conference on radiation-genetics; this is an over-statement of the case. As with previous meetings, this will not be a formal conference with prepared communications, but rather a working party to consider how best to plan future research and to integrate the available effort. It will differ from previous meetings in that a few invitations have been sent to geneticists not actively connected with the three projects. With these as consultants, it is hoped that the most profitable programmes will be devised for future research.

# TWELFTH INTERNATIONAL CONGRESS OF APPLIED PSYCHOLOGY

WITTGENSTEIN once argued that no paper read to a scientific society should last more han fifteen minutes, because anyone who had anyhing to say on any subject could easily say it in that ime. He would probably have regarded with some orror the Twelfth International Congress of Applied sychology, which met in London during July 18–23. ew of the speakers named on the programme took ss than half an hour, and there were more than a undred of them. Yet only four special lecturers had een asked to talk for more than twenty minutes. erhaps many of the others felt that, having come rom the ends of the earth, or thereabouts, they could ustify themselves—to themselves, or to the bodies hich in certain cases had paid their expenses—only y going on and on. Nor was the unbargained-for ime always well spent. In fact, and as usual, the eople who spoke the longest had the least to say.

Nevertheless, the Congress was a good one, and on he whole it took satisfactory account of an important oint made by the president, Dr. C. B. Frisby London), in his opening speech, when he stressed he need, in applied psychology, for paying more ttention to the attitudes displayed to the investiator by the investigated. There was less discussion f his equally important contention that, in the implementation of the results of research, the psychologist ust beware of the hazards of leaving all the work o others. Dr. Frisby said he does not see, in the sychological field, the possibility of an equivalent to he engineer, who can interpret the discoveries of the hysicist. There is, in fact, a danger that attempts may e made by others to apply procedures found useful n situations which psychologically are very different. t the same session, the Lord President of the Council, ord Salisbury, wisely urged that psychologists should e ready to "come down every now and then from he rarified air they normally breathe and be ready o explain, in words the general public can underand, what they are doing and why they are doing . . . . It is because the ordinary man is bewildered hat he is distrustful. He feels there must be a catch n it".

Sir Frederic Bartlett (Cambridge), in a lecture on Timing", gave an admirable exposition of the outcome of recent experimental studies of skill. Two or ore related sequences of events are involved whenever a skilled performance of any kind or level occurs. ne provides the performer with information; the her consists of what he does about it. One is a ceptor sequence; the other is effector. In 'good' ming, each effector constituent enters the sequence such a point that it produces the maximum of sired effect with the minimum of associated effort. inimal effort has two empirical signs: an absence both forced hurry and forced loitering. Experiment as shown that timing is principally controlled by djustments of the relatively stationary intervals in fector sequences. During these intervals, central, erceptual and intellectual activity is demanded; d it is from this that timing derives its remarkable nge of rapid adaptability. In human social affairs, r Frederic argued, timing is just as important as it in the simpler, bodily skills.

Prof. E. Mira y Lopez (Rio de Janeiro) reported e results of experiments on the effect of foresight d attitude on mental output. His subjects had been asked to predict their own health, work, wealth, social prestige, domestic happiness and individual contentment one week, one month, one year, ten years ahead. His main early findings were that the accuracy of prediction depended more on the nature of the facts predicted, and the predictor's psychological make-up, than on the passage of time; that pessimistic predictions about health were more often confirmed than optimistic ones; that predictions about work output were more often accurate than predictions about social prestige, wealth or domestic happiness; and that in the case of neurotic and psychotic subjects fear seemed to dominate their motivation. All this led to a further inquiry into the association between 'force of belief' and accuracy of prediction. A study of attitudes towards psychological tests produced the conclusion that "extrinsic factors, especially of a conative kind, may influence performance in a battery of aptitude tests almost as much as the factors theoretically involved in its normal execution". There is nothing new here, but the additional evidence will be useful.

At the beginning of a symposium on "The Evaluation of Methods in Applied Psychology and the Problem of Criteria", Mr. J. M. Faverge (Paris) strongly advocated the setting up of good criteria at the design stage of investigations; and in doing so he uttered a warning—never unnecessary, it seems—against the hazards of small samples in psychological research. Prof. J. C. Flanagan (Pittsburgh), who followed, spoke some more very good sense on both these points. He said that for the psychologist in the field there is no more fundamental question than, Are we really helping people to solve their problems? The ultimate criteria must always be of the 'on the job' variety; but intermediate criteria, too, are required. In industry, complications often arise through contamination resulting from informal discussion between people responsible for collecting predictor data and others responsible for collecting criterion data.

Prof. R. Bonnardel (Paris), in another symposium, on "The Organization and Application of Research", made a good and uncommon point in arguing that the industrial psychologist is really the only one of his kind who has much chance of studying normal people in the normal conditions in which they spend most of their waking lives. Growing co-operation between practitioners in the field and psychologists in university departments is improving our ability to make use of the opportunity. However, Prof. Bonnardel shared the view of Prof. L. S. Hearnshaw (Liverpool), expressed elsewhere, that the former are still too little inclined to classify, while the latter are apt to classify prematurely. Dr. H. E. Page (Washington), who followed, spoke from a wealth of experience in the administration of science in the U.S. Office of Naval Research. After describing how this organization works, he talked discreetly of some of its major difficulties. One arises from the very great influence exercised by a very few psychologists, through their membership of controlling committees of one kind and another. He did not claim that this is necessarily a bad thing; but he maintained that it is an exceedingly important one. Another difficulty concerned the implementation of research findings. Dr. Frisby had hinted that this is intensified by the entry of untrained people into the psychologist's territory. Dr. Page suggested—without mentioning Dr. Frisby's comment, which he may not have heard—that perhaps the psychologist is himself to blame for this. Indeed, he seemed to extend the main point made by Lord Salisbury, for he went on to say: "More scientists should learn to employ the language and concepts of their users. Many have no desire to do this". He added that the personality of the translator may be more important than his knowledge of information theory.

Prof. O. Klineberg (Paris), who took the chair at a symposium on "Attitudes, Opinions and Behaviour", made a useful and all-too-brief contribution of his own when he took two of his main speakers to task for suggesting that it is unnecessary for psychologists, sociologists and others in this field to agree on the use of terms. It is indeed difficult to discern just what Prof. R. Clémens (Liège) had meant when he said that psychology and sociology differ largely in emphasis. Dr. H. Durant (London) had side-stepped the issue by dismissing it as "partly semantic". It will be interesting to discover, some day, how much of the present-day confusion in this area could be got rid of by the simple expedient of clearing our lines of communication in the way Dr. Klineberg proposed.

The Congress, which met in plenary session for major symposia each morning, and split into six parts each afternoon, for four minor symposia and two series of individual papers, was housed in the Beveridge Hall of the Senate House, University of London, in various theatres in Birkbeck College, and in the Masaryk Hall of the School of Slavonic Studies. One of the four special lectures was given by Prof. C. Pellizzi, head of the Human Relations Division of the European Productivity Agency, which had generously provided simultaneous translation facilities in the Beveridge Hall. Another, delivered at the closing session, was by Prof. M. S. Viteles (Philadelphia). Entitled "The New Utopia", this last lecture provided the applied psychologist with yet another warning that he must be careful how and where he walks. He may find it difficult to avoid making value-judgments of considerable importance to himself and others; but he should at least know when he is doing so. "We cannot allow the fact that our young science is making some contribution to the solution of present-day problems to encourage us to think of ourselves as the architects of the New Utopia."

Among the social events was a banquet at the Hurlingham Club, with a speech by Lord Halsbury in five languages.

ALEC RODGER

# UNIVERSITY AFFAIRS IN GREAT BRITAIN, 1953–54

THE "Returns from Universities and University Colleges in receipt of Treasury Grant for the Academic Year 1953–54", issued by the University Grants Committee[*], shows a further decline of 872 in the number of full-time students—to 80,602, compared with 81,474 in 1952–53 and 85,314 in 1950–51. In the English universities there were 646 fewer full-time men students but 184 more women than in 1952–53; for Wales there were 146 fewer men and 44 fewer women, and for Scotland 201 fewer me
and 19 fewer women. Overseas full-time student
from within the British Commonwealth increased b
368 to 4,607; but part-time students (1,819) wei
23 fewer than in 1952–53. Students from foreig
countries increased by 144 to 3,373 full-time, and b
77 to 1,379 part-time, students compared with 1952
53. There was no appreciable change in the percentag
distribution of full-time students among the facultie
students of technology increased by 43 to 10,03
but those of pure science decreased by 30 to 17,00
the percentage distribution being 12·4 and 21·
respectively, compared with 43 per cent for art
16·4 for medicine, 3·2 for dentistry, 2·6 for agr
culture and 1·3 per cent for veterinary scienc
Although the percentage of arts students was slightl
higher, the number of students (34,673) was smalle
by 243. Full-time advanced students of pure scienc
increased by 245 to 3,290, of technology by 224 t
1,381, of arts by 290 to 3,596, of agriculture by 9 t
290, and of veterinary science by 5 to 12, while thos
of medicine and dentistry decreased by 64 to 89
and only 2,698 students were working for a teacher
diploma compared with 2,900 in 1952–53. Of th
full-time students, 63,560 were reading for a fir
degree, 4,350 for a first diploma, and 12,166 (includin
those working for a teacher's diploma) were engage
in research or other advanced work, the correspondin
figures for 1952–53 being 64,753, 5,064 and 11,65
respectively.

The proportion of assisted students was slightl
higher (71·9 per cent compared with 70·4 per cent i
1952–53), though still smaller than in 1951–52 (72·
per cent); for England as a whole it increased fro
72·9 to 74·2 per cent, and in Wales from 81·1 t
88·5 per cent, but in Scotland only from 55·7 t
56·8 per cent. Parliamentary grants, however, wer
70·5 per cent of recurrent income and only 12 per cen
comes from fees, 4·3 per cent from endowments, 3·
per cent from local authority grants and 1·6 per cer
from donations and subscriptions. For 1951–52 th
corresponding figures were 14·8, 5·2, 4·1 and 1·9 pe
cent, respectively, with 66·5 per cent from Parlia
mentary grants. The ratio of staff to students co
tinued to improve, the full-time teaching staff num
bering 9,514 compared with 9,098 during 1952–5
The increase was chiefly in lecturers (285), but the
were 37 additional professors, 69 more senior lecture
and 12 more readers, assistant professors and i
dependent lecturers, with a further decrease of 12
in assistant lecturers and demonstrators to 1,162.

Of the full-time students, 62,173 were in Englan
4,431 in Wales and 13,998 in Scotland, the distr
bution in English universities and university colleg
being 14,867 at Oxford and Cambridge, 18,125 a
London, and 29,181 at others. Except at Bristo
Leeds, Reading, Southampton and Oxford, whe
there were slight increases, there were slight decrea
in the number of students at English universiti

[*] Universities Grants Committee. Returns from Universities and University Colleges in receipt of Treasury Grant—Academic Year 1953–54. (Cmd. 9477.) Pp. 44. (London: H.M.S.O., 1955.) 2s. 6d. net

English institutions and only 1,189 in Wales and ,802 in Scotland. The proportion of men in residence was 23·5 per cent and of women 42·0 per cent, compared with 22·9 per cent and 41·3 per cent, respect- vely, in the previous year, while 32,987 students 40·9 per cent) were in lodgings and 24,990 (31·0 er cent) at home, compared with 40·0 per cent and 2·7 per cent in 1952–53. Of the 21,153 students dmitted for the first time during 1953–54 (a decrease f 202 on 1952–53), 19,585 were reading for a first egree and 1,568 for a first diploma ; and of those eading for a first degree, 1,382 were less than ighteen years of age and 10,546 were nineteen or more. Of the full-time students, 35,071 out of 47,398 men and 11,036 out of 14,775 women in England were receiving assistance by way of scholarships, xhibitions or other awards from public or private unds ; for Wales the corresponding figures are 2,799 ut of 3,141 men and 1,124 out of 1,290 women ; and or Scotland, 6,024 out of 10,254 men and 1,931 out f 3,744 women. Of the 60,793 full-time men students, 6·3 per cent were in arts, 22·2 per cent in pure cience, 17·0 per cent in medicine and 16·3 per cent n technology ; for the 19,809 women students the orresponding figures are 63·7, 17·6, 14·7 and 0·7 er cent, respectively. Medicine and dentistry claimed 9·6 per cent of the 4,682 part-time advanced tudents, arts 35·6, pure science 9·3 and technology ·8 per cent, respectively, compared with 49·1, 33·8, ·5 and 9·0 per cent, respectively, during 1952–53.

The recurrent income of the universities and niversity colleges of Great Britain increased by 1,413,941 to £31,112,024, of which £21,924,115 was rom Parliamentary grants, £3,724,585 from fees, 1,332,917 from endowments, £1,130,280 from grants rom local authorities and £495,996 from donations nd subscriptions. Of the total income from public unds of £23,054,315 and £8,057,709 from other ources, the University of London received £6,957,728 rom public, and £2,462,874 from other, sources ; the University of Cambridge similarly received £1,436,133 nd £1,332,864 ; for Oxford the corresponding figures re £1,383,461 and £636,418 ; Manchester, £1,125,886 nd £270,863 ; Durham, £999,429 and £324,969 ; Leeds, £933,533 and £268,480 ; Liverpool, £917,590 nd £254,203 ; Birmingham, £900,815 and £240,216 ; Bristol, £819,537 and £319,179 ; Sheffield, £579,598 nd £170,268 ; Nottingham, £500,005 and £105,136 ; nd Reading, £546,373 and £65,241. No other English university or university college had an ncome exceeding half a million pounds, but for the our universities in Scotland the corresponding figures re : Aberdeen, £509,000 and £126,529 ; Edinburgh, 1,093,169 and £373,686 ; Glasgow, £1,114,126 and 332,078 ; and St. Andrews, £545,260 and £116,100. The University of Wales, including the Welsh National School of Medicine, received £1,149,707 rom public funds and £302,169 from other sources. Non-recurrent Treasury grants during the year, in espect of capital expenditure, mainly on buildings, ites, equipment and professional fees, amounted to 5,516,356 compared with £5,746,470 in 1952–53.

Of the total expenditure of £30,260,235—an increase f £1,559,801, or 5·4 per cent on 1952–53—adminis- ration accounted for 7·3 per cent, departmental maintenance 69·4 per cent, maintenance of premises 2·7 per cent, and miscellaneous expenditure 9·4 per cent. Capital expenditure met from income amounted o £358,289 and allocations to reserve to £342,397 ; or 1952–53 these figures were £334,516 and £334,015, espectively. Departmental maintenance, which includes salaries of teaching staff, payments for superannuation, the running costs of laboratories, lecture rooms, libraries and museums and the supply of materials, apparatus, books, specimens, etc., increased by £1,244,181 to £21,005,981, the major increase being 13·2 per cent on departmental wages of technicians and laboratory assistants. Salaries and superannuation of teaching staff amounted to £13,616,426 compared with £13,169,879 in 1952–53, but expenditure on repairs and maintenance of buildings only increased by 4·1 per cent to £1,953,017, although that on rates, insurance, heat, light, water, etc., was up by 9·0 per cent to £1,953,017.

Library expenditure, excluding general maintenance of library buildings, etc., and rates, heat, light, repairs, etc., amounted to £1,203,231, or 4·0 per cent of the total expenditure compared with £1,118,428 or 3·9 per cent in 1952–53, 3·8 per cent during 1951–52 and 3·7 per cent during 1950–51. Of this, £600,647 was for salaries and wages, £147,669 for periodicals and £97,229 for bindings. Of the £290,581 expended on books, £75,652 was in the schools and colleges of the University of London, including £11,732 at the Central Library, £11,890 at the London School of Economics, £9,132 at University College, and £5,963 at the School of Oriental and African Studies. The University of Oxford spent £36,088 on books ; Cambridge, £18,587 ; Manchester, £14,256 ; Liverpool, £9,959 ; Birmingham, £8,686 ; Leeds, £9,150 ; Durham, £10,829 ; Bristol, £8,441 ; and Southampton, £7,509. Expenditure on books and periodicals at a number of English universities and university colleges decreased rather than increased during the year, and increases in general are scarcely in proportion to the mounting costs of both books and periodicals. Only the Universities of London (£39,814), Oxford (£13,530) and Cambridge (£12,448) spent more than £10,000 on periodicals, and only Birmingham (£7,110), Leeds (£5,108) and Manchester (£6,250) more than £5,000. The University of Wales spent £12,805 on books and £8,040 on periodicals. In Scotland, Edinburgh spent £13,930 on books and £7,212 on periodicals ; Glasgow, £12,943 and £9,559 ; St. Andrews, £10,650 and £4,336 ; and Aberdeen, £8,089 and £3,939.

# INTERNATIONAL SCIENTIFIC RADIO UNION

## PROCEEDINGS OF THE ELEVENTH GENERAL ASSEMBLY

THE eleventh General Assembly of the International Scientific Radio Union was held at The Hague during August 23–September 2, 1954, when some three hundred delegates from twenty-two countries participated under the chairmanship of Father P. Lejay, who was re-elected president of the Union until the next Assembly in 1957.

The main functions of the Union are to promote and organize radio research requiring international co-operation, and to encourage the setting-up of common methods of measurement with standardized apparatus. The work is carried out by seven Commissions, and these are concerned with specific aspects of radio research defined by their titles, which were carefully considered and revised at the recent assembly. The present titles, together with the names of the chairmen elected for the session

1954–57 are as follows: I, Radio Measurement and Standards (Dr. B. Decaux); II, Radio and Troposphere (Dr. R. L. Smith-Rose); III, Ionospheric Radio (Dr. D. F. Martyn); IV, Radio Noise of Terrestrial Origin (Mr. J. A. Ratcliffe); V, Radio Astronomy (Dr. M. Laffineur); VI, Radio Waves and Circuits (Dr. S. Silver); VII, Radio Electronics (Prof. G. A. Woonton).

The proceedings of the eleventh General Assembly are being published in eight parts available in either French or English. The first seven parts are to be devoted to the Commission activities; while Part 8, which has just been issued, contains a full account of the administrative proceedings with information on other activities of the Union (10, Part 8 (1955); pp. 125; obtainable from the General Secretary of the Union at 42 Rue des Minimes, Brussels; 14*s*. 6*d*. or 100 Belg. francs).

Although the Union does not now publish the scientific papers which are read and discussed at a General Assembly, a list of titles and authors of the 296 papers and reports submitted at The Hague meeting is given in Part 8; and it is to be noted that the reports of national committees will be published in full in Parts 1–7 according to the Commissions to which they refer. The Union also publishes, six times a year, an *Information Bulletin*, in which are recorded the activities and progress of the Union between successive General Assemblies.

The administrative proceedings (Part 8), referred to above, contains all the resolutions and recommendations adopted by the General Assembly of 1954. Among these is a recommendation accepted from Commission I that the value of 299 792 ± 2 km./sec. should be used in all scientific work for the velocity of electromagnetic waves in a vacuum. It was further resolved that all national laboratories in a position to do so should co-operate in making a comparison of standards of power measurement at frequencies of 3,000 and 10,000 Mc./s.

A full report of the discussions which led up to these recommendations is contained in Part 1 of the proceedings, which was published a few months ago (10, Part 1 (1955); pp. 57; 8*s*. 8*d*. or 60 Belg. francs). This Part 1 contains all the national reports submitted to Commission I, together with the minutes of the meetings of the Commission at The Hague and the resolutions submitted to the General Assembly for adoption. In response to a request received from the International Radio Consultative Committee, it was recommended that members of the International Scientific Radio Union should make observations on the service areas and mutual interference zones of standard frequency transmissions, and also on the type of modulation used by the stations at present in operation. A study of the results of such observations should be of great assistance in the establishment and operation of an effective standard frequency and time service on a world-wide basis.

Among the other activities of the Union reported in Part 1 of the proceedings is an account of the meetings of the committee appointed to consider the programme of work for the forthcoming International Geophysical Year during 1957–58, and brief accounts of the meetings of the Mixed Commission on the Ionosphere and of the Joint Commission on Radio Meteorology held in 1954. The Union committee on the International Geophysical Year has considered various matters relating to the proposed programmes of observations in connexion with meteorology, aurora, ionospheric absorption and 'winds', radi star scintillations, meteors, atmospherics and terrestrial noise. It has also given preliminary consideration to the question of presentation and publication of the results obtained, and mad recommendations on all these matters to the international committee on the International Geophysica Year, which will meet again shortly to formulate th recommended world-wide programme.

It is clear from the two parts (1 and 8) of th proceedings already available that they compris excellent surveys of the relevant fields of radi research, fully documented with references to th original scientific published papers, and the appearance of the remaining parts dealing with the work o Commissions II–VII will be awaited with interest b students and research workers in the field of scientifi radio.

R. L. Smith-Rose

# PRODUCTION AND MEASUREMENT OF ULTRA-HIGH VACUA

BEFORE 1950, pressures of the order of $10^{-7}$ mm of mercury were considered high vacua, an although, undoubtedly, lower pressures were obtained it was not possible to measure them because the mos sensitive vacuum gauges were no longer reliable a such low pressures. To-day, it is possible to produc and measure pressures of $10^{-9}$–$10^{-11}$ mm. of mercury to estimate pressures as low as $10^{-13}$ mm. and, in th case where interest is concentrated on the chemicall active gases present in the space to be evacuated, t estimate partial pressures of these gases of the orde of $10^{-14}$ mm.

A brief but interesting review of these recen developments, together with a summary of th operation of basic pumping apparatus, is given b Dr. J. A. Becker in the January number of the *Bel Laboratories Record* (33, No. 1; 1955). The combination of fore-pump, mercury diffusion pump an cold trap enables pressures of less than $10^{-8}$ mm. t be reached. With the McLeod gauge, pressures dow to about $10^{-6}$ mm. can be accurately measured, an with the ionization gauge, introduced in 1916, lowe pressures by extrapolation can be determined. Th ionization gauge fails, however, when the pressur reaches $10^{-8}$ mm., and work since 1950 has show that ionizing currents, produced by soft X-ray striking the plate of the gauge, and the emission o photo electrons together with an electron curren that reaches the plate even when the plate is at negative potential with respect to the cathode, whic are independent of the pressure, constitute th limiting factors. Bayard and Alpert have propose an arrangement by which these currents may b minimized. The plate is reduced to a fine wire an surrounded by a cylindrical grid with the filamen placed outside the grid. With this modified type o ionization gauge, pressures of $10^{-11}$ mm. of mercur have been measured.

To attain these ultra-high vacua it become important to know the amount of, and sources o residual gas present in the system to be evacuated and Dr. Becker describes four such sources. The are the release of gas from the cold trap; th diffusion of dissolved gases out of the glass and meta parts of the system; the release of gases adsorbe ı the surfaces of the parts of the system and the ffusion in time of gases from the atmosphere rough the glass envelope. Some recent studies of ttering phenomena and observations on the lsorption of gases on clean tungsten, tantalum and olybdenum surfaces conducted in the Bell Labora-ries in connexion with vacua of $10^{-11}$–$10^{-14}$ mm. are iefly referred to. Evaporated films, however, do ›t pump rare gases like helium and neon, and to move them use is made of the ion gauge, which, in ldition to its use as a manometer, can also act as a ımp. Its speed of pumping is much lower than that a mercury diffusion pump or of evaporated films, ıt it has the particular advantages that there is no wer pressure-limit to its pumping action and that can be incorporated in the tube being evacuated.

# COUNTING AND SIZING OF PARTICLES WITH THE FLYING-SPOT MICROSCOPE

y D. CAUSLEY and PROF. J. Z. YOUNG, F.R.S.
Department of Anatomy, University College, London

METHODS for counting and measuring micro-scopic particles by the use of the flying-spot ucroscope have been tested with blood, nerve cells, ust particles and prepared standard sprays. The rstem involves scanning the preparation with twin ›ots of light, differently polarized, and passing the ulses generated by twin photocells to an anti-›incidence circuit and then to a counting unit. The rcuit ensures that a count is registered only on the reep at which one of the spots crosses the particle ; hen both cross it the pulses are made to cancel each ther[1,2]. Every time that a pulse passes to the ›unter, the spot on the display tube is made more ıtense. This provides a visual display that shows hich particles have been counted (Fig. 1).

*Red cell counts.* Red cell counts were carried out ıth the co-operation of Prof. M. Maizels. Twenty samples of blood were counted by the routine visual method in the hospital laboratory. Two sub-samples were taken from each blood and counted both visually and by the machine in our Department. The visual counts were made with the standard method of recording corpuscles that lie upon the lines of a hæmocytometer. The machine counts were made on a microscopic field of known area, including about six hundred corpuscles. Each machine count was repeated three times on the same field, and the mean taken.

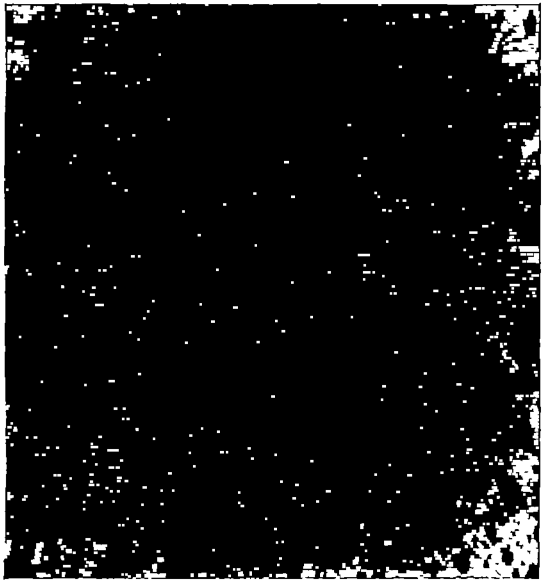

Fig. 1. View of test slide with machine presumed to be counting all particles. The bright spots indicate that a pulse has been passed to the counter

Table 1. HUMAN RED CORPUSCLE COUNTS ($M$/c. mm.)
Columns 2, 3 and 4 are visual counts, 5 and 6 machine counts. Counts 3 and 4 were made by a different observer to count 2. The counts in columns 3 and 5 and 4 and 6 were from the same fillings of the slide.

| 11 | 4·8 | 4·7 | 4·8 | 4·6 | 4·6 |
| 12 | 4·7 | 4·4 | 4·3 | 4·4 | 4·4 |
| 13 | 4·9 | 4·8 | 4·7 | 4·7 | 4·7 |
| 14 | 4·6 | 4·7 | 4·5 | 4·7 | 4·7 |
| 15 | 3·3 | 3·3 | 3·2 | 3·4 | 3·3 |
| 16 | 6·7 | 7·0 | 6·8 | 7·1 | 6·2 |
| 17 | 4·2 | 4·1 | 4·1 | 4·1 | 4·1 |
| 18 | 4·5 | 4·3 | 4·2 | 4·2 | 4·2 |
| 19 | 4·2 | 4·2 | 4·2 | 4·2 | 4·2 |
| 20 | 5·2 | 5·2 | 5·2 | 4·9 | 5·0 |

Table 1 and an analysis of variance show that although the bloods differed greatly, there were no consistent differences resulting from the methods of counting, whether by the hospital laboratory, a second visual observer or the machine.

The replication of the visual and machine counts enabled estimates of variance to be made ; there were no significant differences, but the machine variance was possibly the smaller. The standard deviation is about 0·17 $M$/c. mm. by both methods, giving a coefficient of variation of about 4 per cent.

We may conclude that machine blood counts, though much quicker, are as accurate and consistent as visual ones—perhaps more so. The time involved in preparation of the specimen is equal in the two cases, but the counting takes 4 sec. with the machine, at least 4 min. for the visual observer. The repetition of counts on a given field, which is so quickly under-taken by the machine, gives a further protection against error.

Table 2. COUNTS OF THE NUMBER OF PARTICLES RECORDED BY THE MACHINE AND THE TOTAL OF NUCLEI (AND NUCLEAR FRAGMENTS) MADE BY VISUAL OBSERVATION

Each count is for a strip 500μ wide extending from the pial surface to the white matter of the rat's cerebral cortex, stained with gallo-cyanin

*Counts of nerve cells in sections.* The value of the method for counting nerve cells was tested with sections of the cerebral cortex of the rat stained with gallocyanin to show nuclei and Nissl substance. Counts were made with the machine of all the particles in a series of strips between the pial surface and the white matter, followed by a visual count of all the nuclei and parts of nuclei in the same strips. The figures show a general agreement, and the mean difference does not differ significantly from zero.

*Dust particle counts.* Counting of dust particles may be particularly difficult if there are many near and below the limit of resolution. The maintenance of a constant criterion for counting of imperfectly resolved objects is difficult for both human or machine counting, but is likely to be more variable for the former. Machine counts of such dust were usually considerably higher than those of human observers.

Table 3 shows the results with a series of thermal precipitation samples of steel dust particles. Columns 2 and 3 show visual counts made by observers in Sheffield and London without consultation on standards. There are considerable differences between the counts by visual methods and between these and the machine counts; but the mean differences over columns 2–5 are not significantly different from zero. The replicated machine counts for columns 4 and 5 agree better with each other than do the visual counts of the two observers. Column 6 shows a visual count of the particles of less than 5μ in this material and 7 and 8 are replicated machine counts of this value. The last two agree well with each other but are higher than the visual counts. Presumably this machine is taking a different criterion of what is to constitute a particle at the limit of resolution.

*Sizing.* Estimates of size are made with this system by comparing the pulses generated with pulses of known duration in such a way that successively smaller and smaller particles are rejected from the count[1,3]. In this way the particles in the test-slide shown in Fig. 1 were measured into 5μ-size groups. Table 4 shows comparison of these measurements with those made visually on a photograph at 300 × by three observers. The agreement is remarkably good.

The same method has been used for estimating the number of neurons, as distinct from all particles, in strips of cerebral cortex of the rat, by counting separately the particles greater than and less than 7·5μ.

Table 5 shows that there is moderately good agreement between the estimates obtained in this way and the counts of neurons made visually on the same strips.

*Conclusions.* These results show that the method is capable of providing reliable counts and measurements of a variety of particles. Difficulties have been met in balancing the gain factor in the amplification channels from the two photocells when the contrast of the specimen is poor. Other difficulties arise if the particles overlap or touch, and with objects of shapes involving long re-entrants. For some purposes estimates of the errors due to such factors can be made. The special usefulness of the machine is its speed of operation, making it possible to take more numerous counts than would be practicable by direct vision. For routine counts of easy material, such as blood, it provides substantial economies. For difficult material such as dust, containing particles at the limit of resolution, it may well be that the machine provides approximations that are more consistent than those of a human observer.

Our thanks are due to the Nuffield Foundation for its support, and to Prof. M. Maizels and Mr. F. Fellingham of University College Hospital and Messrs. Maturana, Michie, Sholl, Stanier and Taylor for their help with counting and otherwise, and to Cinema-Television, Ltd., for assistance with equipment.

## Molecular Arrangement in Crystals of the Southern Bean Mosaic Virus Protein

About ten years ago, it was shown[1] that electron icroscopic examination of 'psuedo-replicas' could veal the ordered particle arrangement on the surface f a macromolecular crystal. The necessary preparaons were made by metal-shadowing the dried ystals lying on a glass surface, coating with colloion, freeing this composite layer and dissolving e crystalline deposit from the replica thus produced. he molecular order on several kinds of crystal was en in this way; but a broader application of the ethod was limited by factors such as the fragility f the collodion film and the need to work with proteins ot denatured by vacuum desiccation and the vaporation of metal.

The possibilities inherent in this approach to roblems of crystal growth, as well as structure, have een so great that continued efforts have been made improve this initial technique. Thus 'silicon onoxide' films have been employed[2] to reproduce olecular order in crystals of certain proteins. We ave now found that evaporated films of carbon[3] rmit a very significant advance in both the quality replication and the kinds of macromolecular crystals at can be successfully studied.

Molecular order was first demonstrated using ystals of the southern bean mosaic virus protein[1]. this case, however, as in practically all others, e initial method did not replicate enough different ces to permit a conclusive deduction of the molelar arrangement within the crystal. The numerous ystal faces that can be seen when carbon films are ed for preparing specimens of this substance are ustrated in Figs. 1 and 2. These better results e to be attributed in part to the advantageous echanical and electron optical properties of the carbon membranes, and in part to their chemical inertness and the possibilities this offers of various purifying procedures.

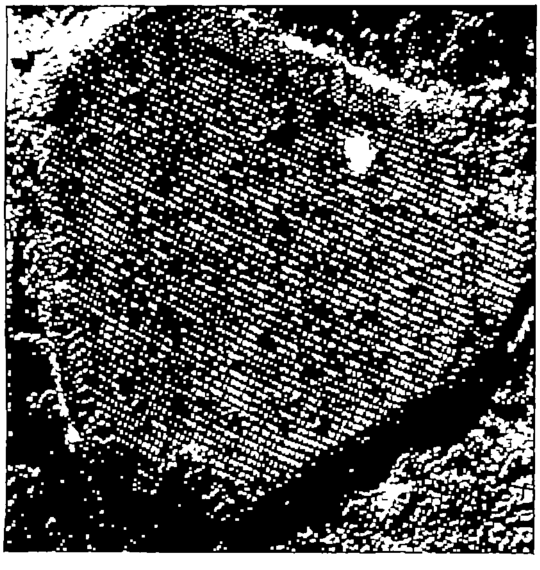

Fig. 1. An electron micrograph of a complete southern bean mosaic virus crystal showing the molecular arrangement on several of its faces. The large face is 110. Magnification × 30,000

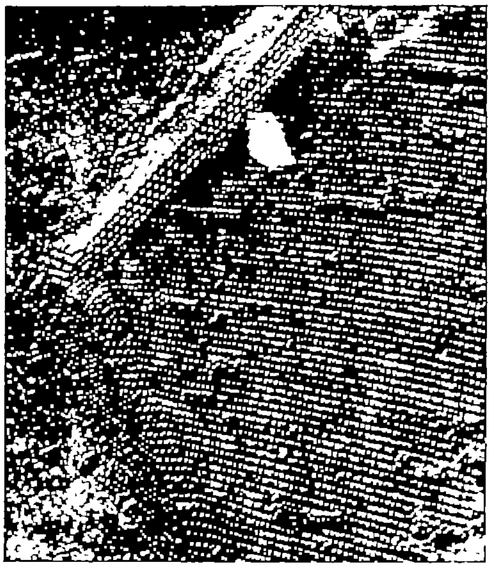

Fig. 2. An electron micrograph of the molecular distribution on several faces developing on one corner of a southern bean mosaic virus crystal. Two [110], [120], [111] and one [100] faces are shown here. Magnification × 30,000

The accompanying electron micrographs are typical of approximately a hundred thus far made of crystals of this virus protein. The crystal symmetry, as determined from measurements of inter-particle spacings and of angles between the edges of crystal faces, proves to be very nearly, if not exactly, cubic. The principal face has invariably been that of a dodecahedron. Faces of the several forms that have been seen have been identified by their relative positions on the crystal and by the particle configurations and spacings they exhibit. This identification has been confirmed by comparisons between the electron micrographs and models built of cork balls which, using the chosen molecular arrangement, reproduce the observed faces. The crystals shown in the figures exhibit faces of the forms [100], [111], [120] and [113], in addition to the dominant [110].

The molecular arrangement in this case is a cubic close packing of essentially spherical molecular particles of diameter about 230 A. The edge-length of the unit cube, containing four of these molecules, is about 325 A.

We have been using this improved method of specimen preparation for studying crystallographic problems connected with the growth of these crystals and for determining the molecular arrangement in a number of other crystalline proteins. These investigations are continuing and will be described in detail elsewhere.

## Terminal Groups of Tobacco Mosaic Virus

THE protein of the tobacco mosaic virus is composed of peptide chains. The first step towards a knowledge of the number and kind of these peptides would be the determination of the carboxylic and amino terminal groups.

Harris and Knight[1] found that the only amino-acid liberated by treatment of the native virus with carboxypeptidase was threonine. Assuming a molecular weight of $40 \times 10^6$ for the tobacco mosaic virus, the number of terminal threonine residues would be 2,700. We have confirmed this experimental result using our tobacco mosaic virus strain[2]. Since objections can be raised against the enzymatic method, Braunitzer[3] determined the carboxylic-terminal groups by the hydrazine method of Akabori[4] and found 2,500 threonine residues but no other amino-acids. Braunitzer[5] has also recently shown that the last three amino-acids at the carboxylic end of the peptide chains are proline–alanine–threonine. These results have also been obtained by Niu and Fraenkel-Conrat[6], so that the number and kind of the carboxylic-terminal groups remain no longer in doubt.

The question of the amino-terminal groups is still under discussion. In the native virus amino-terminal groups are not detectable. After treatment of the virus with trichloracetic acid (*p*H 1·8, 30 min., 85° C.) proline was the only amino-terminal amino-acid that could be detected by the methods of Sanger[7] and Edman[8]; but no carboxylic-terminal amino-acids besides threonine could be observed by the method of Akabori, which makes it unlikely that an α-peptide bond is split by trichloracetic acid[3,8,9].

Repeating our experiments, Fraenkel-Conrat and Singer[10] found evidence for much terminal proline; but they also found with both methods a "host of other terminal amino-acids". Therefore, they suppose that an unspecific hydrolysis of many labile peptide bonds is effected by trichloracetic acid. The contrast between these findings and our own is due to the difficulty of determining the end-groups of the protein. The method of Sanger is complicated, because dinitrophenyl-proline is unstable and decomposes to dinitrophenol during hydrolysis with 6 *N* hydrochloric acid; but the degradation can be partly suppressed by hydrolysis in a nearly anhydrous medium[11]. In both cases, 90 per cent of the dinitrophenyl products are accounted for by dinitrophenol and dinitrophenyl-proline. Partial hydrolysis yields dinitrophenyl-proline, one dinitrophenyl-prolyl-dipeptide, one dinitrophenyl-prolyl-tripeptide[3], and under certain conditions some yellow compounds, which can easily be taken for dinitrophenyl amino-acids.

The method of Edman gives clearer results when properly applied. Fraenkel-Conrat and Singer[10] contented themselves with the measurement of the total absorption of the produced thiohydantoins and with the identification of the free amino-acids obtained by hydrolysis of the unseparated thiohydantoins. It is known that thiohydantoins of pure amino-acids yield more than one amino-acid on alkaline hydrolysis[12]. After hydrolysis of synthetic proline-thiohydantoin (pro-th) with barium hydroxide we found at least four spots on the paper-chromatogram which were ninhydrin-positive and could be taken for amino-acids. Therefore this method is not suitable for identification. We preferred to separate the thiohydantoins by paper-chromatography first and then to determine the pure compounds after elution.

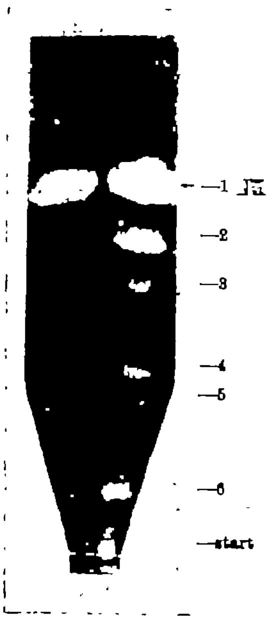

Fig. 1. Chromatogram of the thiohydantoins from tobacco virus protein (right-hand side) and of proline-thiohydantoin (left-hand side)

Fig. 1 is an ultra-viol photoprint of a typic chromatogram: spot 1 ha the same $R_F$-value as pro-th as can be seen from th reference chromatogram t the left. For the identification we hydrolysed th eluate from the spot wit concentrated hydriodic aci (140° C., 90 min.). In thi way we obtained nearly pur proline together with a smal quantity of a by-product In a control experiment wit synthetic pro-th the sam amount of the same by product was obtained. Spo 1 accounts for 65–70 pe cent of the total extinction Spot 2 is a degradatio product of pro-th, produce during the formation o pro-th in acid solution. I accounts for nearly 15 pe cent of the total extinction the other weak spots together to no more tha 10–20 per cent. The spo on the starting line ha not the typical absorption curve of a thiohydantoin The $R_F$-values of the other weak spots correspon to alanine-th, glycine-th and serine-th. These result show that 80–90 per cent of the end-groups i tobacco mosaic virus treated with trichloracetic aci are proline residues, corresponding to 2,400 per mol tobacco mosaic virus.

The impurities (10–20 per cent) need not necessaril be due to an unspecific hydrolysis of tobacco mosai virus. Control experiments[13] with synthetic peptide showed that glycine and perhaps alanine react wit phenyl*iso*thiocyanate, even if they are not terminal These control experiments with synthetic peptide could not be reproduced by Fraenkel-Conrat an Harris[14]. On repeating our experiments with syntheti peptides, we found an error in the chromatographi technique. Phenylthiourea has the same absorptio curve and nearly the same $R_F$ as gly-th, so that th measured amount of gly-th was too high. The presen experiments confirm that non-terminal glycine resi dues react with phenyl*iso*cyanate, but the extent of th reaction is not so high as previously supposed. Afte five hours reaction (40° C., *p*H 8·5) between phenyl *iso*thiocyanate and leu-gly-gly the thiohydantoin o the non-terminal glycine constituted 10 per cent o the total thiohydantoins. The corresponding rati for ala-gly-gly was 30 per cent under the sam conditions. The peptide bonds were not hydrolyse by hydroxyl ions under these conditions. When th time of reaction was shorter, the amount of gly-t was correspondingly smaller, so that it is not surprising that Fraenkel-Conrat and Harris were unabl to detect it.

The determination of the end-groups by fou different methods shows that the protein of tobacc mosaic virus is composed of nearly 2,500 peptid chains with identical terminal groups, as we postulate earlier. It is possible that the sequence of the othe amino-acids in the chains is identical too. The trypti digestion[15] of the protein suggests that every peptid chain contains the same ten digestible peptide bonds.

ne of the eleven fragments, containing twenty-one nino-acids, was isolated in the form of a crystalline, parently homogeneous, dinitrophenyl-derivative.

According to our experiments, the basic unit of e protein has a molecular weight of 15,000–17,000 d contains 130–150 amino-acids. This is in agreement with the analytical data of Knight[16] and with e observations of Schachman and Hersh[17] that the otein of tobacco mosaic virus dissociates in the esence of detergents into subunits of molecular eight 10,000–20,000.

The masking of the amino-terminal group in the tive virus is not due to the nucleic acid, as we eviously supposed; but we hope to elucidate its ture shortly.

## Lunar Occultation of a Radio Star and the Derivation of an Upper Limit for the Density of the Lunar Atmosphere

On April 26, 1955, the moon's position was favourable for the observation from England of the passage f the moon across the large-diameter radio source the constellation of Gemini. This radio source, o. 2C.537 of the Cambridge survey[1], having A. 06h. 13m. 37s. and Dec. 22° 38′ (1950.0), has een identified by Baldwin and Dewhirst[2] as the alactic nebulosity *IC.443*, photographs of which, ken with the 48-in. Schmidt camera at Palomar, veal a filamentary structure contained within a rcular region of 24·5′ radius.

The Besselian elements of this and other occultations have also been computed by Link and Neuzil[3], ho have indicated the value of such observations determining the detailed distribution of radio rightness' across the source and in investigating the resence of a lunar atmosphere.

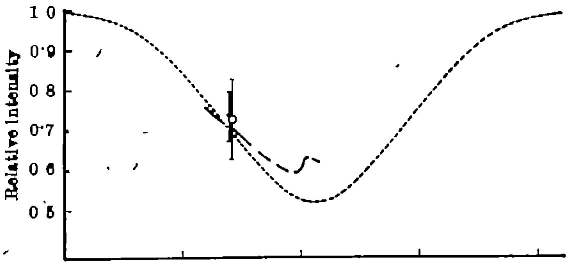

Fig. 1. Relative intensity during the occultation of April 26, 1955, ⊢●⊣ and ⊢○⊣ are measurements at $\lambda = 7 \cdot 9$ m.; — —, measurements at $\lambda = 3 \cdot 7$m.; · · · · · ·, curve predicted from the measurements of Baldwin and Dewhurst

Observations of the source were made at Cambridge t wave-lengths of 7·9 and 3·7 metres, during April 4–28 inclusive. Two independent sets of observations ere made at 7·9 metres, using large fixed-aerial ystems which provided information for about ten inutes near the meridian transit of the source. At ·7 metres the two pairs of the large Cambridge radio lescope[4] were used as interferometers of low solving power. In order to extend the period of observation, phasing cables were introduced into one pair of aerials, so that the reception pattern was deviated 8½° from the meridian. In this way it was possible to observe the source continuously for 25 min.

The results obtained are illustrated in Fig. 1. This shows the relative intensity observed at the time of transit, using the two 7·9-metre systems, together with the limits of error. The full line shows the results obtained at 3·7 metres; the gaps are due to intermittent man-made interference which caused a deflexion many times greater than the normal noise-level of the record. In the absence of interference, the accuracy of the results obtained at 3·7 metres is believed to be better than 5 per cent. The dotted line indicates the relative intensity predicted from Baldwin and Dewhirst's distribution derived on the assumption of circular symmetry.

Both sets of observations show good general agreement with the latter curve, but the reduction is less; the most probable explanation of this effect is that more radiation originates in the bright arch on the north-following side (Fig. 2), than in a symmetrical model.

An examination of the 3·7-metre curve shows, in addition, a marked irregularity near the time of maximum phase (16h. 30m.). Consideration has been given to the possibility that this discontinuity might be due to the reception of enhanced solar radiation scattered by the lunar surface; the absence of any evidence for solar activity some hours before and on succeeding days indicates that this explanation is most improbable and suggests that the effect must be explained in terms of irregularities in the 'bright-

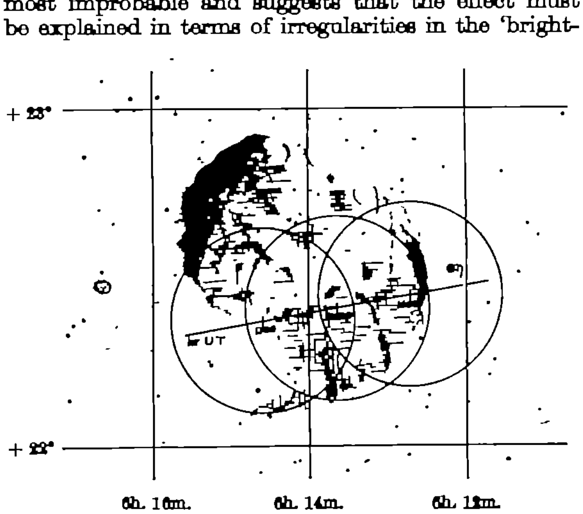

Fig. 2. Moon's position, as seen from Cambridge on April 26, 1955, in relation to *IC.443*. The centre of the radio source is indicated by a cross

ness' across $IC.443$. At this time the moon's west limb is uncovering a part of the well-defined filament on the extreme preceding side, near $\eta$ Geminorum (Fig. 2). The rise in radio intensity indicates that the radiation from this area is about five times greater than that expected from the circularly symmetrical distribution of Baldwin and Dewhirst.

Both this result and the magnitude of the intensity observed at the time of maximum phase are therefore consistent with the hypothesis that the radio emission originates mainly in the regions of strong $H\alpha$ emission.

If the identification of the increase of radio intensity with the uncovering of the bright area is correct, then the relative times of these occurrences may be used for estimating the density of the lunar atmosphere. Two effects would delay the radio occurrence: diffraction at the moon's limb, which at 3·7-metres wave-length produces a delay of about one minute, and refraction in the lunar atmosphere. Link[3] has computed the latter effect for a number of different models of the lunar atmosphere.

The observations show that the total delay cannot exceed 4 min., and the electron density in the lunar atmosphere cannot then exceed $10^4$ cm.$^{-3}$ if the scale-height lies in the range 50–1,500 km. Although the composition may differ considerably from the terrestrial atmosphere, it seems probable that, on the moon's sunlit side, the degree of ionization would be as great as that of the $F$-region. On this supposition the density of the lunar atmosphere must be less than $10^{-12}$ of the density of the terrestrial atmosphere at sea-level, a figure 1/1,000 of the previous upper limit derived by Dollfus[6] from optical measurements.

This work was carried out at the Cavendish Laboratory as part of a programme of research supported by the Department of Scientific and Industrial Research, to which one of us (G. R. W.) is indebted for a maintenance award. We also wish to thank Mr. J. H. Blythe for the use of one of the 7·9-metres aerial systems.

## Reliability of Atomic Masses in the Chromium – Germanium Region

FOR the past thirty years, beginning with F. W. Aston's observation of small deviations from his whole-number rule, the mass spectrograph has been used for determining atomic masses. One of the first significant results of this work was the experimental proof[1] by Bainbridge in 1933 of Einstein's mass–energy relationship. This led to the frequent use of atomic masses to check the correctness of experiments which measured the energy balance in nuclear transformations. In the intervening years the accuracy with which atomic masses can be determined by mass spectroscopy has greatly improved: however, the techniques for studying nuclear reactions have more than kept pace. As a result, when a discrepancy now exists between mass spectroscopic and transmutation values, th mass spectroscopist often finds himself playing th part of uncomfortable defendant, rather than that ( patronizing judge. Such is our position in th communication.

In a recent communication[2] from the Universit of Glasgow, J. M. Reid and I. F. Wright have reporte experiments disproving the existence of the 0·56-MeV γ-ray which has been rumoured to follow the positro emitted by copper-62. This result, which has als been obtained[3] by R. H. Nussbaum *et al.*, gives ris as Reid and Wright point out, to a serious di crepancy (~ 0·65 MeV.) between the value of th copper-63 and nickel-62 mass difference compute from transmutation data and that calculated on th basis of recent precision mass measurements. The also remind us that a similar discrepancy exists in th case of the zinc-64 and nickel-64 mass difference, an properly advise the cautious use of mass values in th region of the Periodic Table. As mass spectroscopist we are naturally concerned about these matters, an actually have been aware for some time of the exist ence in this region of several such inconsistencie including these two. This communication is intende to direct attention to these inconsistencies and t suggest that a particular element, nickel, may be th principal cause of them.

In the hope of discovering some systematic dis crepancy between mass spectroscopic and trans mutation data, we have calculated a large numbe (thirty) of mass differences in the region chromiu to germanium, using both sources of informatio The mass spectroscopic differences have been ob tained, primarily, from the masses obtained[4,5] at th University of Minnesota by Prof. A. O. Nier and hi collaborators and, quite secondarily, from some de rived[6] in our own laboratory. The calculation of th transmutation differences would normally be physically exhausting undertaking, since it woul involve the use of a great deal of information scattere widely throughout the scientific literature. Fortu nately, at the suggestion of the Sub-committee o Nuclear Constants of the National Research Counc (U.S.A.), this information has recently been com pletely tabulated. In our calculations, we hav therefore made exclusive use of the table of "Nuclea Disintegration Energies", compiled[7] by D. M. Va Patter and W. Whaling, and the "Table of Tota Beta-Disintegration Energies", compiled[8] by R. W King, both appearing in the October 1954 issue c the *Reviews of Modern Physics*. The numerica results of these calculations are not included here since they present a rather formidable array; bu we can provide them for those particularly intereste

These calculations reveal that, between stabl nuclides of the same element (for example, iron-57 iron-56, nickel-61 – nickel-60, etc.), the transmutatio and mass spectroscopic differences are reasonabl consistent, particularly if one assumes that the actu mass spectroscopic errors are somewhat larger tha the stated statistical ones. The only serious in consistency exists in the case of the zinc-67 – zinc-6 difference.

In the case of mass differences between stabl nuclides of different elements (for example, iron-54 chromium-53, gallium-69 – zinc-68, etc.), the situatio is quite different and far less satisfactory. Here onl four of the sixteen calculated differences agree withi the stated probable errors, and many are far outsid the limits, in particular, those differences involvin one or other of the isotopes of nickel. In these fiv ses (nickel-58 – iron-57, nickel-) – iron-57, copper-63 – nickel-62, ckel-64 – copper-63, and copper-– nickel-64), without exception, e agreement is poor and always such a direction as to indicate at the masses of nickel determined ass spectroscopically are too low y ~ 60 × $10^{-6}$ atomic mass units. here appears to be no other large stematic effect.

On this basis, we are putting forard the hypothesis that the nickel asses are in error, and hope in e near future to make some xperimental attempts to confirm allay this suspicion by investiating the behaviour of nickel ions the mass spectrograph under arying conditions of pressure. In e meantime, we feel that, within e framework of the foregoing marks, the atomic mass values for e other elements in the chromm – germanium group may be sed with reasonable confidence.

## Radioactive Fall-out in Kingston, Canada

During the recent nuclear tests carried out by the Jnited States Atomic Energy Commission, we have hecked the radioactive fall-out in Kingston, a small Ontario town situated some 2,200 miles north-east of he testing grounds. Our sampling period extended rom February 15 to May 28, 1955, and included all he test explosions reported by the Press.

For a large part of the sampling period the ground vas covered with snow; samples were taken from the op layer of the snow, melted and 600-c.c. samples iltered and the filter paper counted with a thin-window β-counter. When the snow left, rain was ollected and 600-c.c. samples were filtered and ounted. When all precipitation failed, dust was ollected on a tray, washed off, filtered and counted.

A record of the activity with the background ubtracted is shown in Fig. 1. Arrows along the bscissa indicate the day that a test was conducted, and in all cases except April 9 only one bomb was fired. Two explosions were detonated on this date. The largest reported explosions were set off from 500-ft. steel towers and were equivalent to 30 kilotons T.N.T. These were fired on March 7 and 22 and on May 5 and 15. They were detected, but they did not display as high an activity as smaller explosions on March 1 and April 9 and 15.

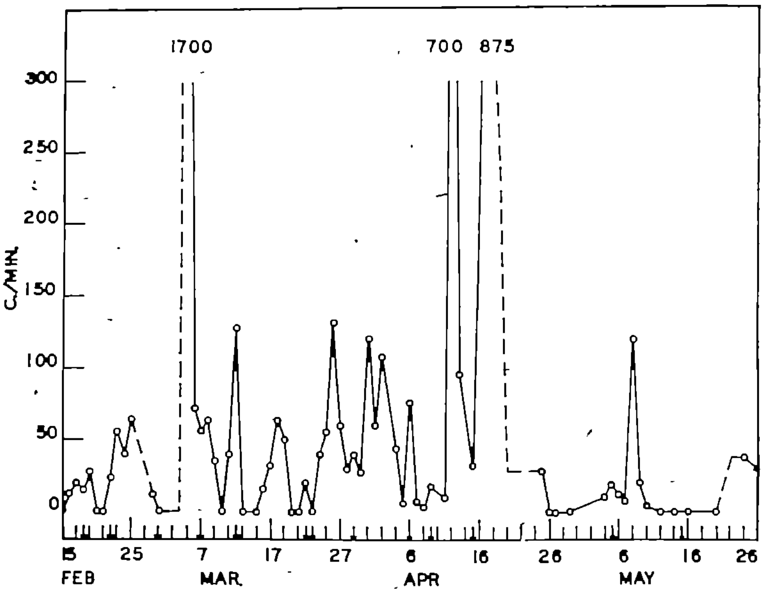

Fig. 1. Plot of counts per min. above background versus time. Dotted lines indicate lack of data because of equipment breakdown. Circles are experimental points and arrows indicate nuclear tests as reported in the Press

Meteorological factors seem to outweigh the magnitude of the bombs at such a great distance from the site of the explosion. The high activities detected on March 6 and 7 were found in fresh snow and the activities detected on April 12 and 18 were found in fresh rain. There is generally a one-to-one correspondence between tests and activity peaks, except for an unexplained peak at April 6, which may be due to some previous explosion.

## Long-Period Fading in Medium-Wave Radio Signals

Considerable work has been done on the interpretation of periodic fading observed in continuous-wave radio signals reflected from the ionosphere. Appleton and Beynon[1] observed both slow and fast types of periodic fading in the records of short-wave radio signals which were interpreted by them as due to magneto-ionic origin. Tantry and Khastgir[2] reported long-period fading in the medium-wave records and assumed it to be due to interference of lower trajectory ordinary and extraordinary waves. This interpretation has been confirmed by Satyanarayana and Dharambir Rai[3] by using polarized receiving aerials. The object of the present investigation was to study the periodicity of this slow type of fading in medium-wave records, and compare the observed periodicity with the

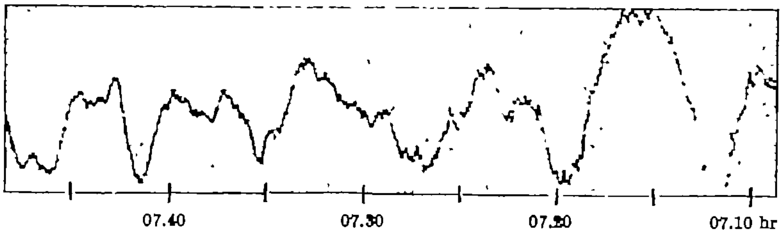

Fig. 1

values obtained from a theoretical calculation of the path-lengths in the ionosphere.

Records of variations of signal strength of continuous-wave transmissions on 1·42 Mc./s. from Madras received at Waltair (600 km. distant from Madras) during the morning hours have been obtained using the conventional type of continuous-wave recording equipment. Hourly records were taken daily during 0700–0800 hr. I.S.T. over a period of one month during May 1954. The records thus obtained showed a long-period fading of the order of 7 min. per cycle on which are superposed other types of short-period fading. A typical record obtained on May 14, 1954, is reproduced in Fig. 1. The long-period magneto-ionic fading on which is superposed a quick fading is clearly seen in the record. It may also be noticed that the fading period gradually decreases with time. On an average, nine peaks are observed in the one-hour records.

The expected periodicity in the records is then determined by using a method of theoretical calculation of the path-lengths in the ionosphere based on the magneto-ionic theory due to Appleton[4] and Hartree[5]. Appleton[6] has applied the magneto-ionic theory for the calculation of path-lengths of both the magneto-ionic components for the case of vertical incidence only; but Booker[7] has worked out the theory for the most general case of propagation at oblique incidence and obtained a quartic equation, which has enabled us to obtain the appropriate curves for the ordinary and extraordinary components of the radio wave for a frequency of 1·42 Mc./s.

The magnetic field at the level of the *E*-region has been assumed to be 5 per cent less than the ground value and the scale-height has been taken to be 15 km. The equivalent paths for the ordinary and extraordinary components in the *E*-region have thus been calculated for 0700–0800 hr. I.S.T. using a method of graphical integration and assuming Chapman's distribution for the electron density in the ionosphere. The critical frequency values at these times for the month of May have been taken from the data reported by the Physical Research Laboratory, Ahmedabad. Table 1 gives the calculated values of total equivalent paths from the transmitter to the receiver along with the path-differences between the two components expressed in terms of the wave-length λ of the radio signal.

From the table it is evident that the path-difference changes by 8·6 wave-lengths during the one hour of recording, giving rise to an average period of 7 min. per cycle, which is in good agreement with the observed values, as can be see from the record reproduced Fig. 1. This apparent good agre ment is possible because of th assumption of a value of 15 kı for the scale-height followi Pfister[8], who assumed this val in order to account satisfactori for the variations with latitude the heights of maximum ion conce tration of the *E*-region. Calcul tion of the path-lengths on the basis of parabol and cosine law distributions of electron density in tl *E*-region have given values which are much differe from the observed results.

Table 1

| | 0700 hr. | 0800 hr. |
|---|---|---|
| Path of the ordinary component | 4,104·6 | 3,852·9 |
| Path of extraordinary component | 3,956·9 | 3,713·8 |
| Path difference between the ordinary and extraordinary components | 147·7 | 139·1 |

Full details of this investigation will be publish elsewhere. We are indebted to the Council of Scienti and Industrial Research for financial assistance this research work.

## Flexural Rotational Slip as the Main Deformation Process in the Torsion of Zinc Crystals

Hitherto there has been no successful elucidatio of the mechanism by which torsion of single crysta occurs. We have now, however, established that i zinc the main deformation process is rotational slip but in general with pronounced flexure of the sli lamellæ—a process we propose to call 'flexur rotational slip'.

For torsion about [0001], when this is nearl parallel to the axis of the cylindrical crystal (in th case examined, [0001] was 9¼° from it) practicall pure rotational slip on (0001) is indicated by: (1) th final spiral form of lines initially scribed lightly o the surface, parallel to the torsion axis [0001] (2) the form of the slip lines on the surface of th twisted crystals; (3) the practically perfect cleavag of the twisted crystals even after 90°/cm. twist (4) electron diffraction photographs from thes cleavages, virtually identical with those from cleave undistorted crystals; (5) optical reflexes from prism type etch facets.

The experimental results under (1), (2), (3) and (5 show that the torsion is macroscopically practicall uniform; those under (2), (3), (4) and (5) show th rotational slip of (0001) lamellæ; and those under (4 show these lamellæ are virtually undeformed an greater than 200 A. thick, while from those under (5 they are probably much thicker than this. Plasti torsion of 1-cm. lengths cleaved from this 0·97 cm diameter crystal (bonded by 'Araldite' resin to bras flats mounted in a lathe) first occurred at abou

1 kgm. cm. couple, which had to be increased to tain larger torsion, for example, to 2·75 kgm. cm. ter 7°/cm. torsion.

A crystal having [0001] at 38° to the rod axis was risted (held in split collars in chucks) in a lathe to °/cm. twist. Cleavage then gave highly smooth rfaces, optically and in electron diffraction closely milar to those from undistorted crystals, except at they were saddle-shaped. While calculation owed that a shape of this form would be expected be taken up by the inclined (0001) lamellæ if the d had been isotropic and in homogeneous torsion, e actual shape of the cleavage differed appreciably om that calculated. The difference is clearly due slip on (0001), associated with the very limited ange' possible in the dimensions of the lamellæ. nis also modifies the flexure imposed on the lamellæ, ading to deviation from circular cross-section of the d to the observed three-lobed form (the lobes rresponding to three rounded protruberances iralling around the rod surface).

These features were even more pronounced in a ystal having [0001] at 62° to the rod axis, and risted through 66°/cm. Curved slip lines (*S*-shaped side view) were prominent; and though a first eavage resulted in a fracture nearly normal to the d, along (0001) planes of the twins developed there ring the fracture, a good cleavage was then hieved by impact of a knife parallel to the slip lines, nfirming that these were still traces of (0001) planes.

These results for zinc establish for the first time at the main process during torsion is rotational p, in general with macroscopic flexure of the otherse undistorted slip lamellæ. Previous observations r example, in aluminium and iron[2]) now suggest at flexural rotational slip can also occur in cubic ystals even in compression or extension, the slip nellæ being not necessarily parallel to the same ane as in normal translational slip. We are testing ese points further.

## Complex Formation between Montmorillonite and High Polymers

PREVIOUS workers[1] have shown from X-ray easurements that organo-clay complexes may be med by certain organic compounds entering tween the montmorillonite sheets. In the course mvestigating the interaction of various high lymers and montmorillonite, a new kind of comx has been observed, involving the edge faces of clay crystals only. This type of complex, tentaely called a 'peripheral' complex, has the same xis spacing as pure montmorillonite when dry, but fers markedly in its swelling pattern in dilute t solutions.

Up to the present, peripheral complexes have been med only from carboxylated polymers containing positively charged groups along the chains, such sodium alginate, carboxymethylcellulose and polyylic acid. The complexes were prepared by adding a known amount of polymer to an aliquot of a suspension of sodium saturated Wyoming bentonite and then drying the polymer-clay mixture to form an orientated clay disk 0·04 mm. thick. It was necessary to adjust the *p*H of the suspension to about the half neutralization point of the polymer before complex formation occurred, the latter being indicated by a rapid increase in the viscosity of the suspension. The swelling of flakes 0·5 cm. square cut from the disk was then observed in $N/2$ sodium chloride and distilled water (see Figs. 1 and 2 of flakes in water). A flake prepared from clay alone would, of course, disperse immediately in water.

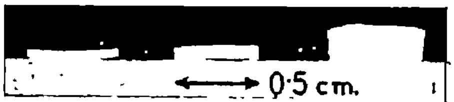

Fig. 1. 15, 7·5 and 4·0 per cent polyvinyl alcohol in water
Fig. 2. 125 per cent maleic acid vinyl acetate copolymer in water

In the case of inter-lamellar complexes, if a large amount of a polymer, such as polyvinyl alcohol, were added, swelling was small both in water and $N/2$ sodium chloride. However, flakes containing a concentration of polymer just sufficient to prevent dispersion, although still swelling little in $N/2$ sodium chloride, did expand appreciably in water. Flakes of peripheral complexes swelled to a limited degree in $N/2$ sodium chloride, approximately equal to the swelling of flakes made from clay alone, whereas in water highly vertically expanded gels were formed. The addition of further polymer did not reduce the vertical swelling but led to a marked lateral expansion in the case of more flexible polymers like polyacrylic acid. A similar swelling pattern has been observed with polymers added to pure illite and kaolinite.

It is suggested that in the peripheral complexes the polymer links the edge faces of the clay crystals by a series of hydrogen bonds to the oxygen and hydroxyl atoms exposed at the edges of the crystals. Further, it is considered that the polymer chains provide only the lateral links holding the clay crystals together, the vertical attractive force necessary to balance the repulsive osmotic pressure being due to electrostatic attraction between the crystals themselves. A full discussion of the experiments and the forces involved will appear elsewhere. The work is of practical importance in that commercial 'soil conditioners' increase the cohesion of soil crumbs by either one of the above methods.

I wish to thank Mr. L. F. Long for taking the photographs.

## Separation of Rare-Earth Elements

The fifteen rare earths, together with actinium, yttrium and scandium, represent 20 per cent of the stable elements. Their properties are less known than those of the other elements mainly owing to the difficulties in their isolation.

The most important step towards the preparation of pure rare earths was the application of ion-exchange chromatography with complexing agents by Tompkins *et al.*[1], Spedding *et al.*[2] and Boyd *et al.*[3] in 1947. The ion-exchange work also provided comparative results on the complex chemistry of the rare-earth elements. One may even consider that these are the first valid results in rare-earth chemistry, as such data as melting points of acetylacetonates previously measured must now be regarded with suspicion because the purity of the rare earths then employed has since been demonstrated to be usually less than 80 per cent of the major constituent.

Elution sequences were hence used for comparisons of rare earths and transuranic elements with such complexing agents as citric acid or hydrochloric acid[4].

Other separation methods were also evolved and depended again on differential complexation of the rare earths, for example, paper electrophoresis[5,6] and paper chromatography[7,8] where separations were recorded with citric, tartaric and lactic acids, hydroxyquinoline and acetylacetone as complexing agents. It is easy to envisage further separation methods based on complex formation: gas-liquid partition chromatography with volatile complexes (for example, acetylacetonates), inverse phase partition chromatography with complexed rare earths, alumina chromatography with complexing developer, etc. These would all be not only of analytical but also of chemical interest as they could provide data for the volatility or extractability, etc., of the complexes employed.

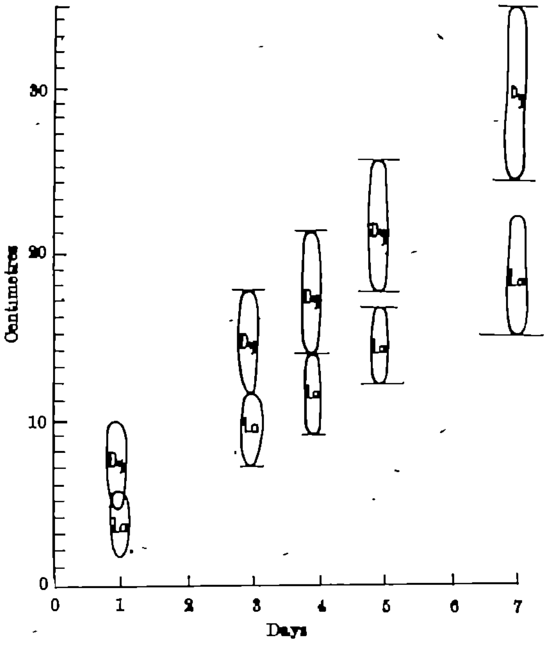

Fig. 1. Separation of lanthanum and dysprosium with ethanol–10 per cent 2 *N* hydrochloric acid as solvent. Descending development and the solvent allowed to run off the paper. The spots shown are larger than those obtained in other experiments as the paper was somewhat overloaded to permit detection with ease even with very diffuse spots

The complexing methods have not, however, contributed to knowledge of the hydrated (or no complexed) rare-earth ions. Alumina chromat graphy has provided some data in this direction but ion-exchange separations with non-complex rare earths did not prove successful[10].

An interesting paper by Gotte and Patze on t paper chromatography of fission products[11] mentio the partial separation of lanthanum and yttrium wi ethanol containing 30 per cent of 2 *N* hydrochloric ac as solvent. The authors of the aforementioned pap also state that other rare earths all stay with lant anum, thus suggesting a specific separation yttrium from the rare earths.

As in all ion-exchange series, yttrium is usual found between dysprosium and holmium, it w decided to investigate this anomaly of yttrium in t non-complexed state.

Owing to the lanthanide contraction, the differen of the ionic radii between lanthanum and dysprosiu will be about as big as the difference betwe barium – strontium or cæsium – rubidium. Th when a solvent is used in which (as in the case Gotte and Patze[11]) the $R_F$ difference between bariu and strontium is 0·16, the difference between lant anum and cerium would not be likely to exce 0·016. Thus in the search of a solvent for rare ear separation it is best to examine mixtures of lanthanu with a high atomic weight rare earth such as dy prosium or holmium where the difference of the ion radii is of the same order as that between, for e ample, barium and strontium. In our previous wo with non-complexed rare earths we did not consid this question, and reached a conclusion similar that of Gotte and Patze, namely, that rare eart do not separate with solvents such as ethanol–nitr acid (M. Lederer, Thèse, 1954).

In the experimental work mentioned below, employed a lanthanum–dysprosium mixture as t indicator for the exploratory work with vario solvents. This mixture has the ionic radius differen discussed above, and when the chromatogram sprayed with hydroxyquinoline, lanthanum produc a green fluorescent spot (in ultra-violet light), a dysprosium yields a black fluorescent spot. Hen even very small partial separation effects are readi observed.

We first examined the solvent ethanol – 30 p cent 2 *N* hydrochloric acid proposed by Götte a Patze[11] using descending development and allowi the solvent to flow over the paper for several day Thus instead of $R_F$ values we shall only state t distances moved, usually with lanthanum as referenc In the above solvent the following mixtures we separated :

| | | |
|---|---|---|
| Lanthanum – yttrium | lanthanum spot<br>27 1–30·3 cm. | yttrium sp<br>22 6–36·0 c |
| Lanthanum – dysprosium | lanthanum spot<br>24 7–28·8 cm. | dysprosium s<br>29·6–35·1 c |
| Lanthanum – ytterbium | lanthanum spot<br>27 8–30·7 cm | ytterbium s<br>31·2–34·8 c |

As seen, not only do lanthanum–yttrium separate co pletely but also lanthanum–dysprosium and lant anum–ytterbium are well separated. However, t lanthanum spot moves rather rapidly, and for separation of rare earths closer to each other th lanthanum–dysprosium it was considered desirab to look for a solvent with generally lower $R_F$ valu so as to permit better separation by longer develo ment with the solvent running off the end of the pap

Ethanol containing 10 per cent of 2 *N* hydrochlor acid appeared to be the best choice of the ethan hydrochloric acid mixtures yielding already comple

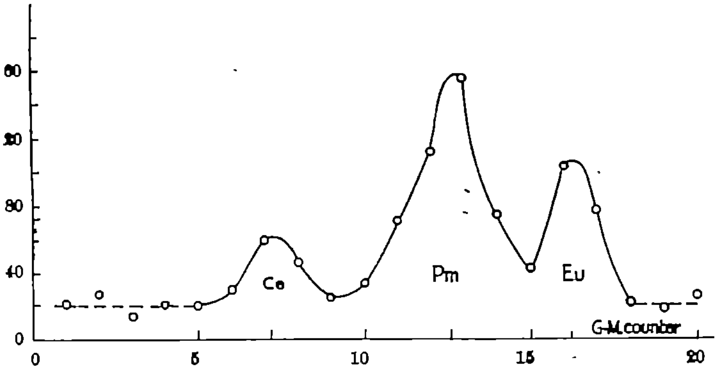

Fig. 2. Separation of cerium, promethium and europium. Solvent: ethanol, 90; 2 $N$ hydrochloric acid, 10. Descending for 5 days

ıthanum–yttrium separations with a development only 29 cm. (solvent front). The $R_F$ values under ese conditions are as follows:

| Ion | $R_F$ value | Ion | $R_F$ value |
|---|---|---|---|
| ıthanum | 0·11 | Dysprosium | 0·196 |
| etium | 0 16 | Ytterbium | 0 17 |

order to investigate if prolonged development l improve the separations, two sets of experiments re conducted: (1) The development of a lanthum–dysprosium over various lengths of time and the chromatography of mixtures of closer rare ths.

(1) The separations of lanthanum–dysprosium was ried out for various times between one and en days, and the fronts and rears of the spots are own in Table 1.

In the above experiments the amounts of rare ths were relatively large, so as to make detection ier with very diffuse spots as are formed on proged development. These results are better visuald by Fig. 1.

(2) To make detection easy, mixtures of two or ee rare earths were prepared so as to give adjacent ts of different fluorescence when sprayed with droxyquinoline and viewed under ultra-violet light. e mixtures thus studied were lanthanum–europium–rium, lanthanum–yttrium and lanthanum–dyssium with spots of lanthanum, yttrium, ytterbium, etium, erbium and europium run on the same sheet paper.

On four different chromatograms running for three four days the mixtures lanthanum–europium–rium, lanthanum–yttrium and lanthanum–dyssium were always completely separated into tinct spots. $R_F$ values of lanthanum, europium and rium did not change from the pure solution to the xture. From the few rare earths so far examined appears that the indicator mixture lanthanum–sprosium was fortunately chosen, as the $R_F$ values erbium, ytterbium and lutetium are inferior to se of dysprosium. Thus from the results so far to nd, the movement of the free ions does not follow e sequence of ionic radii, but reaches a maximum near dysprosium–yttrium. The following distances moved in three days on one particular chromatogram may be cited: lanthanum, 7·0 cm.; europium, 8·8 cm.; yttrium, 9·4 cm.; dysprosium, 11·3 cm. (lanthanum mixed with dysprosium, 7·1 cm.); and erbium, 10·2 cm.

Table 1

| Time of levelopment | Lanthanum spot | | Dysprosium spot | |
|---|---|---|---|---|
| | Front (cm.) | Rear (cm.) | Front (cm.) | Rear (cm.) |
| 1 day | 5·3 | 1·6 | 10 0 | 4·5 |
| 3 days | 11·3 | 7·0 | 17·5 | 11 4 |
| 4 ,, | 13 7 | 9 2 | 21·0 | 13 7 |
| 5 ,, | 16 7 | 11 9 | 25·3 | 17·9 |
| 7 ,, | 22 0 | 15·2 | 35 0 | 24·4 |

At this stage of the work a practical problem was suggested to us, namely, the purification of a source of promethium obtained from the fission products at Harwell and known to contain cerium and europium isotopes as impurities. A hydrochloric acid solution of about 1 mc. of the promethium was chromatographed for five days with ethanol containing 10 per cent 2 $N$ hydrochloric acid and separated as shown in Fig. 2 into three peaks of activity. A detailed study of the gamma spectra indicating the purity of the fractions obtained will be published later.

The results so far already indicate, however, numerous applications, and appear to be the first successful chromatographic separations in which the rare earths are separated as free ions instead of as complexes.

# Effect of Sunlight on Mixtures of Vegetable Oils and Pigments

SUNLIGHT, according to recent work in these laboratories, is much more active in producing peroxides in the extracted crude lipids of certain vegetables (Lee, F. A., unpublished data), than in ordinary oils[1]. It is known that peroxides are produced when chlorophyll dissolved in oils or in oleic acid is exposed to light[2,3] and that, in the presence of chlorophyll, certain oils autoxidize[4]. Since the crude lipid preparations from green vegetables contain carotenes as well as chlorophyll, the effect of sunlight on colourless or nearly colourless oils mixed either with carotene or with carotene and chlorophyll was investigated. Chevallier *et al.*[5] studied the changes taking place in mixtures of triolein and carotene. They found that β-carotene retards the oxidation of triolein in the dark, but accelerates it in the light of a mercury-vapour lamp. In addition, chlorophyll dissolved in triolein prevents the oxidation-accelerating action of β-carotene in the presence of mercury-vapour light. In that work the chloro-

Table 1. EFFECT OF PIGMENTS ON PEROXIDE FORMATION IN ALMOND AND BRAZIL NUT OILS EXPOSED TO DIRECT SUNLIGHT

|---|---|---|---|---|---|
| Almond oil | | | | | |
| extracted | 5 | 56 | 565 | 57 | 65 |
| expressed | 17 | 63 | 577 | 106 | 252 |
| Brazil nut oil | | | | | |
| extracted | Trace | 107 | 559 | 95 | 85 |
| expressed | 8 | 147* | 639 | 133 | 133 |

* Average of two rather poor checks. The accuracy of this figure may be open to question.

† Carotene added as follows: 3 mgm. to ether-extracted oils, 1 mgm. to expressed oils.

Note: The figures for the exposed samples in this table are net values, in that the figures for the unexposed control and the figures for the pigments exposed alone were subtracted.

phyll and the β-carotene solutions were separated by glass. The chlorophyll solution completely absorbed the violet and blue rays emitted by the lamp.

Almond oil was prepared by shelling fresh sweet almonds, removing the integuments by carefully scraping, cutting into small pieces and drying by lyophilization. Following this, they were ground and extracted with redistilled, peroxide-free, anhydrous ethyl ether for twenty-four hours in the dark. Brazil nut oil was prepared in a similar way.

20-mgm. samples of each of these oils were transferred to white porcelain evaporating dishes 100 mm. in diameter. One set was analysed for peroxide immediately, using the method described in previous publications[6,7]. Another set to which nothing was added was exposed to direct sunlight (10,000 ft.-candles) for an hour along with the other samples. Pigments were added to other lots, as shown in Table 1.

Another set was run in which the conditions were the same with the following exceptions: the nuts were not lyophilized, and the oils were expressed with a Carver press instead of being extracted with ethyl ether, and 1 mgm. of carotene was used instead of 3 mgm. The data are presented also in Table 1.

On exposure to 10,000 ft.-candles of sunlight for one hour, chlorophyll causes approximately a tenfold increase in the peroxide value of almond oil and five-fold increase in the peroxide value of Brazil nut oil. Probably because of its reducing action, carotene retards the production of peroxide. The peroxide values of carotene-oil mixtures were about equal to those of the untreated oils. With the addition of mixtures of carotene and chlorophyll, a higher peroxide value was obtained for almond oil and either a lower or an equal value for Brazil nut oil than with the addition of carotene alone.

## Relationship between Orotic Acid and Animal Protein Factors of Casein

FOR several years the various manifestatio
induced in rats by the deficiency of new dieta
factors present in crude casein, that is, animal prote
factors of the casein, have been investigated in tl
laboratory. A natural diet, such as that propos
by Randoin and Causeret, namely: ground cere
(wheat, maize, barley, oats, rye), 88 per cent; whe
germ, 5 per cent; crude casein, 5 per cent; calciu
lactate, 1·5 per cent; sodium chloride, 0·5 per cen
carrots and fresh vegetables *ad libitum* twice a wee
enables normal growth and reproduction for ma
generations; but a series of changes occur wh
the crude casein is replaced by a casein purified
repeated washings with water[1–4]. These changes m
be summarized as follows: (1) alteration of the bod
weight curve; (2) high mortality in the newly bor
(3) histological lesions of the cells, mainly
the hepatic cells where lysis and necrobiosis occu
(4) cutaneous lesions and high incidence of ne
plasms in the surviving rats of the first generatio

These changes are accentuated in a second gener
tion and might be referred to as a 'late deficiency
They seem to be elicited by the gradual exhausti
of the reserve of the so-called animal protein facto
present in the organism fed on a normal diet and a
transmissible from the mother rats to their offsprin

Investigations conducted in our laboratory hav
demonstrated that these factors are not identifiab
either with the vitamins essential for the rat, i
cluding $B_{12}$[1,2], or with methionine and cystine[3]
with the various mineral elements present in th
Osborne–Mendel salt mixture[3].

Recently, our attention has been directed to th
significance of orotic acid in this type of deficienc
This has been occasioned by the fact that: (*a*) sma
quantities of whole cow's milk, which, as alread
known, is one of the richest natural sources of orot
acid[6], are able to solve one of the most dramat

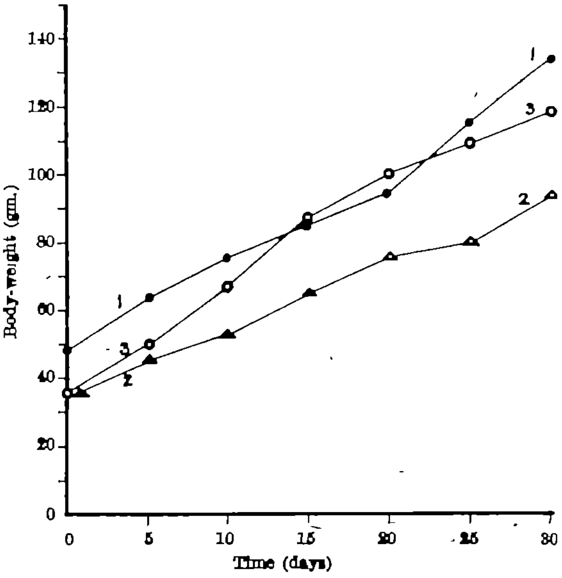

Fig. 1. Body-weight curves for rats fed on: (1) —•—•—, Randoin and Causeret diet containing crude casein; (2) —△—△—△—, Randoin and Causeret diet containing purified casein devoid of the animal protein factors; (3) —○—○—○—, Randoin and Causeret diet containing purified casein devoid of the animal protein factors and supplemented with orotic acid.

Each curve represents the mean body-weight values for twenty animals, male and female in equal number pects of the deficiency, namely, the high mortality the newly born[1]; (b) in our purified casein, which ems to be solely responsible for the lesions observed, e orotic acid content is much decreased[7].

We have therefore now investigated the influence orotic acid upon the body-weight curve of rats cking the animal protein factor.

Rats of the Sprague–Dawley strain, devoid of the imal protein factor, being the sole survivors of the st generation, were fed from weaning (21 days of e) on our deficient diet, which was supplemented th 1,000γ of orotic acid (manufactured by Bio- emical Inc., Co., Cleveland, Ohio) per 100 gm. of od. The results obtained are shown in Fig. 1.

The body-weight values for rats fed on a normal andoin and Causeret diet containing crude casein, d supplemented with 1,000γ orotic acid per 100 gm. diet, are not included, since orotic acid failed show any influence in these conditions.

From the above results, it appears evident that otic acid may be one of the growth-factors for ts deficient in animal protein factors, but not for rmal rats. This suggests a possible relationship tween orotic acid and the animal protein factors casein.

Further work is in progress in our laboratory in der to ascertain the role of orotic acid in the merous lesions induced in rats by the deficiency casein animal protein factors.

## A New Method for the Microbiological Assay of Thiamin (Vitamin $B_1$)

THIS purpose of this communication is to present few experimental results obtained during the course f some investigations carried out to determine the utritional requirements of a fungus, *Tuberculina ersicina* (Ditm.) Sacc., isolated in 1949 by Dr. B. 'Oliveira from aecidia of *Puccinia rubigo-vera tritici*, nd since maintained in the fungus collection of the lant Pathology Department of Estação Agronómica acional, Sacavém, Portugal. These results seemed o be of special significance, and may eventually lead o the development of a new method of bio-assay of hiamin (vitamin $B_1$).

Several vitamins were tested as growth-promoting actors for *T. persicina*, namely, thiamin, biotin, iboflavin, pyridoxin, nicotinic acid, inositol and antothenic acid (this latter in the form of its calcium alt). The vitamins were added aseptically to a ynthetic basal medium (autoclaved for 20 min. at 07° C.) of the following composition: $KH_2PO_4$, 1·5 gm.; $MgSO_4.7H_2O$, 0·5 gm.; $KNO_3$, 2·0 gm.; dextrose ('Difco'), 15·0 gm.; agar ('Difco'), 15·0 gm.; distilled water, 1,000·0 ml. The final pH was adjusted to 5·2. Purified agar (according to Robbins and Ma's technique[1]) was consistently used throughout the experiments to avoid possible sources of error. After incubation for twenty days at 20° C., it was noticed that the plates to which thiamin had been added not only showed good growth of the fungus colony but also displayed an unusual pigmentation of the medium, whereas those lacking this factor remained colourless, even when all the others were present.

In further experiments, devised to ascertain the optimum levels of thiamin concentration for pigment production, liquid cultures were used preferentially; series of flasks were thus prepared by adding various amounts of vitamin $B_1$, within the range $5 \times 10^{-4}$ γ/l. to $5 \times 10^{4}$ γ/l. to the basal medium without agar. The cultures were incubated for thirty days, at the end of which time very striking differences in the coloration of the liquids were observed. When measured spectrophotometrically, these differences seemed to be directly related to the amount of vitamin $B_1$ present in the original culture medium. There was almost no pigment formation in the liquids of the control flasks, nor in those in which the thiamin concentration was lower than $5 \times 10^{-3}$ γ/l. Above $5 \times 10^{2}$ γ/l. of thiamin, there was a marked decrease in pigment formation, as may be seen from Table 1.

Table 1

| Thiamin concentration (γ/l.) | Optical density at λ = 3700 A. | Thiamin concentration (γ/l.) | Optical density at λ = 3700 A. |
|---|---|---|---|
| 0 | 0·083 | 5 | 0·900 |
| $5 \times 10^{-4}$ | 0·083 | $5 \times 10$ | 1·300 |
| $5 \times 10^{-3}$ | 0·082 | $5 \times 10^{2}$ | 0·280* |
| $5 \times 10^{-2}$ | 0·203 | $5 \times 10^{3}$ | 0·250* |
| $5 \times 10^{-1}$ | 0·430 | $5 \times 10^{4}$ | 0·178* |

* Culture medium diluted to 1 : 10 to permit a good reading.

Further experiments are being carried out to determine the influence of the different sources of carbon and nitrogen on pigment production by *T. persicina* in the presence of thiamin. Results will be discussed in a future publication.

## The Duplication Mechanism of Deoxyribonucleic Acid

RECENT investigations have shown it to be more and more probable that genes are deoxyribonucleic acid molecules. Furthermore, Watson and Crick[1] have given strong arguments for assuming that these molecules consist of two polynucleotide chains wound helically in a large number of turns around a common axis and tied together by hydrogen bonds between pairs of corresponding purines and pyrimidines, so that adenine can pair only with thymine and guanine only with cytosine. In order to explain the duplication process of the deoxyribonucleic acid molecule, Watson and Crick have suggested that the two polynucleotide chains may be separated and each chain catalyses the synthesis of a complementary chain. The difficulty in this process is the separation of the two parallel helices which are highly intertwined and locked together by a large number of hydrogen bonds, the breakage of all of which would need a large amount of energy. To overcome this difficulty, Delbrück[2] has suggested a somewhat different mechanism, whereby the two chains are separated and later re-combined by a series of breaks and reunions in a zipper-like fashion. However, this mechanism also seems both too complicated and somewhat improbable since, for example, all these breakings of bonds would again need a considerable amount of energy.

A simpler mechanism for the duplication of deoxyribonucleic acid molecules is made possible by the recent suggestion of Gamow[3], that there seems to exist a one-to-one correspondence between the double polynucleotide chain of a deoxyribonucleic acid molecule of the Watson and Crick type and the single polypeptide chain of a protein (or enzyme) molecule of the Pauling and Corey type, whereby the linear information contained in a deoxyribonucleic acid molecule is translated one-to-one into that of a protein molecule, each one of the possible (about twenty) quadruples of purines and pyrimidines corresponding to one of the possible (about twenty) amino-acids. By this one-to-one correspondence, Gamow shows that a protein (or enzyme) molecule can be built up 'on the inside' of the double helix of a deoxyribonucleic acid molecule so that the order of the amino-acids is uniquely determined by the order of the purine–pyrimidines. However, since this correspondence is one-to-one, this process may obviously be inverted, the protein molecule now serving as the template or mould for the building up of a deoxyribonucleic acid molecule 'around' the protein molecule as axis, so that the order of the purine–pyrimidines is now uniquely determined by the order of the amino-acids. The new deoxyribonucleic acid molecule would therefore be an exact replica of the original one, apart from possible 'casting errors' which would lead to a 'mutated' form of the original gene deoxyribonucleic acid molecule.

In the mechanism here suggested, the protein 'pictures' of the gene deoxyribonucleic acid molecules built up by the Gamow process would thus serve a double purpose: (*a*) as suggested by Gamow, they may be the enzymes which catalyse, and thus control, the biochemical reactions in growth and development of the cytoplasm of the cell; (*b*) they may be the templates or moulds for the duplicati
process of the gene deoxyribonucleic acid molecul
Furthermore, the duplication of virus deoxyrib
nucleic acid molecules can proceed by this same mec
anism, thus explaining the fact that viruses can on
duplicate themselves when their deoxyribonucle
acid gets inside the cells of other organisms, becau
only here can the virus deoxyribonucleic acid mol
cules find both the protein material for the templat
and the nucleic acid material for the casting
replicas.

## Anti-tumorigenic Action of Iodinated Compounds

As one of us (F. B. O.) had observed that th
administration of a mixture of aqueous solutions
potassium iodide and potassium iodate induce
favourable effects in cancer patients, we decided t
carry out an experimental study in rats.

White rats received an implant of spindle-cell sa
coma of a strain obtained by courtesy of Prof. E. Cru
Coke, of the Institute of Physiological Chemistry of th
University of Chile. Animals were given a dose
0·2 ml. per 100 gm. body-weight of a solution contai
ing 0·482 *M* potassium iodide and 0·083 *M* potassiu
iodate, three times a day, via oesophageal tube. I
this way, 43 mgm. of iodine per 100 gm. of body
weight was administered to each of these animal
every 24 hr. Previous experiments with ninetee
animals thus treated, giving the iodine solution eithe
two weeks before or on the same day as the implanta
tion of spindle-cell sarcoma, showed that the treat
ment produces a marked inhibition on the growth
the tumour; in more than 70 per cent the tumour
disappeared leaving no traces, whereas twenty-on
untreated animals developed large tumours and die
Of the first nine animals treated, six still survive–
116 days after treatment was suspended.

We then used another experimental series consist
ing of two groups of thirty-eight animals each. I
one group, the treatment was begun forty-five day
before the implantation of the sarcoma. The tumour

## Oxidative and Photosynthetic hosphorylation by Chloroplast Fragments

Recently, Arnon, Allen and Whatley[1,2] described otosynthetic phosphorylation by isolated whole loroplasts; but chloroplast fragments were only ebly active in their experiments. On the other hand, have prepared a chloroplast fragment fraction hich caused oxidation of Krebs's cycle acids sociated with phosphorylation[3]; but this preparaon was inactive in photosynthetic phosphorylation. modifying the preparative procedure, I have now tained a chloroplast fragment fraction which used disappearance of inorganic phosphate either the presence of citrate or in the light.

Spinach leaves were ground, and the particles were ntrifuged and washed as described previously[3], cept that 0·02 *M* potassium ascorbate was used in ese procedures instead of citrate (cf. the legend of ig. 1). The fraction precipitated between 250 *g* d 1,000 *g* was referred to as the whole chloroplast action, and chloroplast fragments were sedimented 1,000–10,000 *g*. As shown in Fig. 1, the whole loroplast fraction decreased inorganic phosphate pon illumination, while, in the dark, the content inorganic phosphate remained nearly constant en in the presence of citrate. On the contrary, e chloroplast fragment fraction caused disappearnce of inorganic phosphate either in the presence citrate or upon illumination.

The conditions necessary for the photosynthetic hosphorylation by the chloroplast fragments seemed mewhat different from those for the oxidative osphorylation. The photosynthetic phosphorylaon was accelerated markedly by the addition of boflavin monophosphate but not by coenzyme I or , and the system seemed to be more stable at higher H values, at lower temperatures, in the absence of ded fluoride and in the presence of ascorbate. nder these conditions the photosynthetic phoshorylation proceeded approximately linearly with me during the reaction period of sixty minutes ig. 2). Calculated from the data of Fig. 2, the chloroplast fragment fraction, upon illumination, caused disappearance of 13·7 micromoles of inorganic phosphate per hour per 0·5 mgm. of chlorophyll at 10° C., *p*H 7·6, under aerobic conditions. The value for the whole chloroplast fraction was 20·9 micromoles. These values are in fair agreement with that of Arnon *et al.* (16·7 micromoles) for whole chloroplasts under anaerobic conditions.

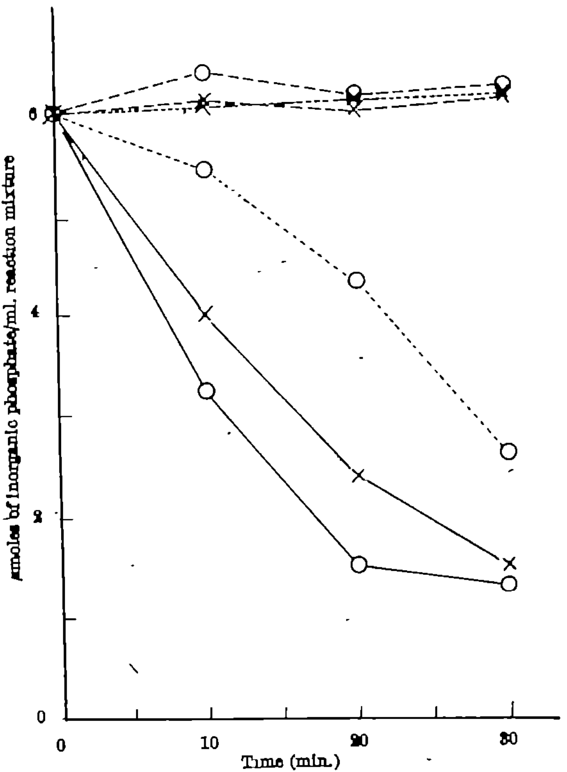

Fig. 1. Phosphorylation in the presence of citrate or in the light. ○,○ Chloroplast fragments containing 0·34 mgm. chlorophyll per ml. of the reaction mixture; ×,×, whole chloroplasts (0·18 mgm. chlorophyll/ml.); solid lines, in the light (c. 2,000 lux) without citrate; broken lines, in the dark without citrate; dotted lines, in the dark with 0·02 *M* citrate.

Spinach leaves were ground in a solution containing the following components in final concentrations: sucrose, 200 m*M*; sorbitol-borate buffer of *p*H 7·2, 50 m*M*; ethylene-diamine tetra-acetic acid, 20 m*M*; and potassium ascorbate, 20 m*M*. The particles were washed with, and suspended in, a solution of similar composition, except that the concentration of ethylene-diamine tetra-acetic acid was 10 m*M*. The reaction mixtures contained the following components in final concentrations: $MgCl_2$, 4 m*M*; $KH_2PO_4$, 6 m*M*; adenosine triphosphate, 1 m*M*; ethylene-diamine tetra-acetic acid, 3·3 m*M*; sucrose, 200 m*M*; glucose, 30 m*M*; sorbitol-borate buffer of *p*H 7·2, 67 m*M*; potassium ascorbate, 15 m*M*; NaF, 8 m*M*; yeast hexokinase, c. 14 units/ml. and crude coenzyme concentrate from pig liver, 0·5 mgm./ml. Erlenmeyer flasks of 50 ml. capacity each containing 3 ml. of the reaction mixture were shaken in the air in a bath of 15° C., and, at intervals, aliquots were withdrawn, deproteinized and inorganic phosphate was determined colorimetrically

Thus, at present, it seems to me that the photosynthetic phosphorylation is the coupling of the Hill reaction with the oxidative phosphorylation. My chloroplast preparations showed such high activities in photosynthetic phosphorylation, as described above even under aerobic conditions, and, in contrast to the finding of Arnon *et al.*, I have, thus far, not obtained results indicating that anaerobiosis was more favourable for obtaining higher activities of the reaction. However, in view of the fact that chloroplast fragments were always more active in photosynthetic phosphorylation than in oxidative phosphorylation, the photo-reduction product of the Hill reaction, that is, the substrate for the subsequent oxidative phosphorylation, may be different from,

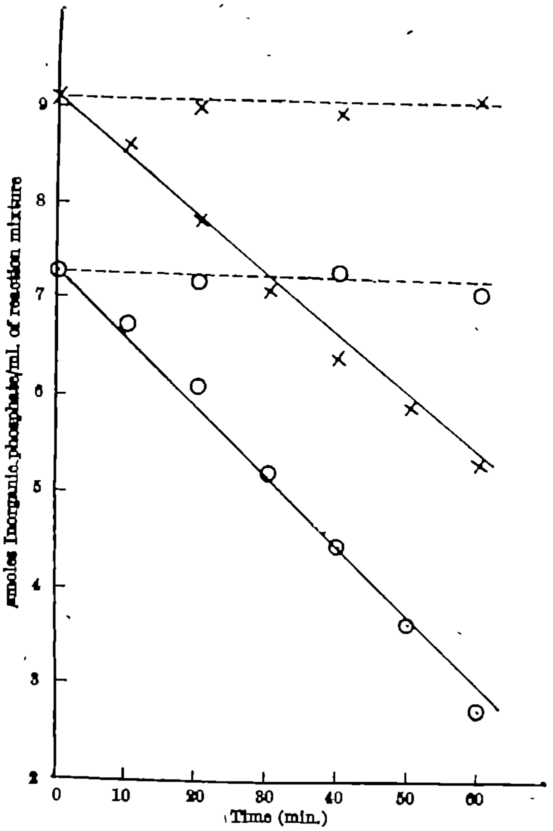

Fig. 2. Time course of the photosynthetic phosphorylation. ○,○, Chloroplast fragments (0·165 mgm. chlorophyll/ml.); ×,×, whole chloroplasts (0·090 mgm. chlorophyll/ml.); solid lines, in the light (*c.* 2,000 lux); broken lines, in the dark. Grinding and washing were carried out in similar solutions, as described in Fig. 1, except that 0·05 *M* *tris*-(hydroxymethyl)-aminomethane (tris) buffer of *p*H 7·6 was used instead of sorbitol-borate buffer of *p*H 7·2. Reaction mixtures contained the following components in final concentrations: $MgCl_2$, 4 m*M*; $KH_2PO_4$, 8 m*M*; adenosine triphosphate, 1 m*M*; ethylene-diamine tetra-acetic acid, 1·5 m*M*; sucrose, 200 m*M*; glucose, 30 m*M*; tris buffer of *p*H 7·6, 67 m*M*; potassium ascorbate, 20 m*M*; yeast hexokinase, *c.* 14 units/ml., and riboflavin monophosphate, 0·1 mgm./ml. Reactions were carried out at 10° C. in the air

and may be a more suitable substrate for the reaction than, the externally added citrate or reduced pyridine nucleotides. The inactivity of the whole chloroplasts in the oxidative phosphorylation may be explained by the impermeability of the added substrate to the site of the reaction.

I thank Prof. S. Funahashi for his advice and interest in this work.

## Effect of Inhibition of Cholinesterase on the Motility of the Small Intestine

EXPERIMENTS with anticholinesterases have shown that the pseudocholinesterase of rat, dog and man can be inhibited without eliciting any symptoms of acetylcholine accumulation in the intact animal[1]. On the other hand, inhibition of the true cholinesterase by more than 80 per cent leads to acute disturbances indicative of acetylcholine poisoning, while comple inhibition of the true cholinesterase activity is i variably fatal. These results support the origir classification of the cholinesterases according physiological function as proposed by Mendel a Rudney[2], who surmised that the destruction of acet choline in the body, wherever it takes place rapidl is brought about mainly, if not exclusively, by t true cholinesterase.

Later experiments indicated that the contractio of the longitudinal muscle of the small intestine we increased by di*iso*propyl phosphonofluoridate amounts which did not cause more than 20 per ce inhibition of the true cholinesterase while inhibitir the pseudocholinesterase almost completely[3]. The results seemed to indicate that the pseudocholineste ase is concerned with the hydrolysis of acetylcholir in the muscle of the small intestine. Howeve Shelley[4] recently reported results which sugge that the pseudocholinesterase does not play a important part in the destruction of acetylcholir in the isolated longitudinal muscle coat of the rabb intestine *in vitro*. She found that the increase in th tone of the intestinal muscle ran parallel with th percentage inhibition of the true cholinesterase b eserine and by di*iso*propyl phosphonofluoridat regardless of the degree of inhibition of the pseud cholinesterase effected by these compounds. Th increase in tone in the longitudinal muscle fir appeared when less than 20 per cent of the tru cholinesterase was inhibited, and reached a maximu with total inhibition of this enzyme.

The results obtained in our experiments on th motility of the small intestine of the cat under mo physiological conditions have been briefly reporte previously[5] and confirm those obtained *in vitro* b Shelley[4]. For these experiments, a method wa designed by which the contractions of a segment c the small intestine with intact blood supply could b measured *in situ*, and the changes in intestinal motilit and cholinesterase activities were determined afte intravenous injections of three anticholinesterases di*iso*propyl phosphonofluoridate (DFP), tetraethy pyrophosphate (TEPP) and the prostigmine analogu (*Nu* 1250) described by Hawkins and Mendel[6]. Thes investigations also indicated that the pseudocholin esterase is not of primary importance for the hydrolysi of the acetylcholine formed in the small intestine while there is, on the other hand, a fairly clos correlation between the degree of inhibition of th true cholinesterase activity by the various compounds and their effects on the intestinal motility.

In confirmation of Shelley's findings, the motilit of the longitudinal muscle was increased when th true cholinesterase was inhibited by about 20 pe cent. The circular muscle appeared to be somewha less sensitive to all three anticholinesterases an required about 40 per cent inhibition of the tru cholinesterase before its motility was increased. I confirmation of previous observations on intac animals[6], it was found that peristaltic movement appear when the true cholinesterase is more tha 80 per cent inhibited. This difference may be explained by the fact that the normal rhythmic movements of the small intestine are due, to a large extent to acetylcholine of non-nervous origin, whereas th peristaltic movements depend on synaptic transmission in the myenteric plexus[7].

It is conceivable that there is a continuous equilibrium between the release and hydrolysis of acety choline in the muscle of the small intestine whic ffected by a relatively small inhibition of the true linesterase activity. On the other hand, a small ibition of the true cholinesterase appears to have measurable influence on the transient depolariza- produced by the intermittent release of acetyl- line at the synapses in the central nervous system, enteric plexus and ganglia and at the myoneural ctions in the skeletal muscles. As suggested by lley[4], the high acetylcholine content and the rela- ely low cholinesterase concentration in the longi- linal muscle of the small intestine may also be portant factors in determining the high sensitivity this tissue to inhibition of the true cholinesterase.

## Concentration of *Brucella* Vaccine

Frozen-dried *Brucella* vaccine is in various ntries distributed in multiple-dose containers for nomy of production and convenience in use. The mber of viable, normal organisms per ampoule termines the number of subcutaneous doses one poule contains[1].

The dosage per ampoule may be raised by a simple, expensive and labour-saving technique.

Sodium-carboxy-methyl-cellulose as a substance th protective qualities which does not encourage e growth of micro-organisms had given some omise as preservative in viable liquid *Brucella* ccine[2]. It was also found to be an agglutinant for *ucella* organisms. Combination of these two pro- rties suggested its use for concentrating suspensions organisms before freeze drying.

Carboxy-methyl-cellulose (commercial, high vis- sity, type '70') was added to the *Brucella* vaccine spension in the form of a sterile watery solution d at the rate of 16 gm. per 4,000 ml. containing proximately $6 \times 10^{14}$ viable cells[3]. After agitation a 5-litre flask, this was held at 4·0° C. for 18 hr. allow for sedimentation of the cells. The super- tant was siphoned off and *mist. desicans* was added the sediment. The mixture was pipetted into npoules and freeze-dried on an Edwards Model . 3 apparatus.

Pre-drying counts showed $1,375 \times 10^{9}$ viable ganisms per ml., and a 50 per cent survival-rate was tained when the ampoule was sealed in pure nitro- n after freeze-drying. One half ml. dried in a 1·0 c.c. npoule thus contained $337 \times 10^{9}$ organisms or five ses of vaccine by the conventional standards.

Carboxy-methyl-cellulose is harmless, inert and mmonly taken internally. Parenterally it produced effect in 0·1 per cent solution under the skin. ological reactions of the concentrated vaccine in inea pigs and cattle have given results identical those obtained with vaccine made from agar surface culture. It was tested only in the prescribed density of $12 \times 10^{9}$ organisms per ml.

## Hæmoglobin *E* in Indonesia

Five abnormal forms of human hæmoglobin, hæmoglobin *S*, *C*, *D*, *E* and *G*, have been described in addition to the normal adult (*A*) and fœtal (*F*) hæmoglobins.

Hæmoglobin *E*, which until recently was thought to be rare, has been found to have a high incidence among the Thais[1]. Its pattern of incidence may be of much anthropological importance. In the present communication I am now reporting the finding of hæmoglobin *E* among the Indonesian peoples.

In a previous communication, cases of Cooley's anæmia in Indonesian children have been described[2]. In order to identify the exact nature of this congenital anæmia, I made an electrophoretic study of the hæmoglobin in the erythrocytes of these individuals. At the same time a survey of pathological hæmoglobins among Indonesians was carried out.

The method employed was a slight modification of that described by Smith and Conley[3] using veronal buffer *p*H 8·6 and ionic strength 0·05. The hæmoglobin solutions were run 8–14 hr. at room temperature.

Five hundred samples of blood taken at random from patients at the Central General Hospital in Djakarta were examined. Most of the patients were from west Java, and the rest were from different parts of Indonesia; 479 were Indonesians, 13 were of mixed Chinese and Indonesian blood, and 8 were Indo-Europeans. Eighteen individuals showed a pathological hæmoglobin in addition to normal adult hæmoglobin. This pathological hæmoglobin has exactly the same electrophoretic mobility as the hæmoglobin *E* we received from Thailand (hæmoglobin *C* is slower and hæmoglobin *S* migrates faster). Its visible and ultra-violet spectra were the same as those of adult hæmoglobin. I therefore diagnosed hæmoglobin *E*.

Of the eighteen individuals carrying hæmoglobin *E* in their blood, sixteen were Indonesians, one was of mixed Chinese and Indonesian blood and one was an Indo-European. The incidence among the 500 individuals examined was therefore 3·6 per cent. No other pathological hæmoglobins were found electrophoretically.

Hæmoglobin solutions prepared from the erythrocytes of cases described as Cooley's anæmia in my earlier paper[2] were also examined. Two of the cases have only adult and fœtal hæmoglobin, which is the pattern expected in Cooley's anæmia. The third case

(case 2 in our publication, whose father was no longer alive for observations) was a case of Mediterranean-hæmoglobin *E* disease. In addition, two other cases of Mediterranean-hæmoglobin *E* disease were discovered.

In those carrying the trait, hæmoglobin *E* formed the minor component, whereas in Mediterranean-hæmoglobin *E* disease the pathological hæmoglobin was the major component (judged from the intensity of the spots on the paper). This fact was also observed by Chernoff *et al.* in their study of hæmoglobin *E* in Thailand. There was no increase in fœtal hæmoglobin (by Singer, Chernoff and Singer's method[4]) in any of the carriers of the trait examined.

Lehman (personal communication) recently found two carriers of the hæmoglobin *E* trait among people from Ceylon.

It is probable that hæmoglobin *E* is prevalent in South-East Asia, and a study of its incidence in different areas of this part of the world is of anthropological interest.

This work is continuing, and a more complete report will be made in the future.

Drs. Itano, Bergren and Sturgeon, who kindly made a comparative study of my pathological hæmoglobin with their own hæmoglobin *E*, found that the former is exactly the same as the original hæmoglobin *E* described by them in 1954. Dr. Itano established the identity by moving-boundary electrophoresis both at pH 6·5 and 8·6.

## Predation Pressure and Evolution in Lake Nyasa

IN papers dealing with the evolution of fishes in the Great Lakes of East and Central Africa, Worthington[1-3] postulates that a major contributory factor to the great adaptive radiation shown by the family Cichlidae in certain lakes, notably Victoria, Edward and Nyasa, has been the absence from their waters of active predators. The theoretical implications of this suggestion have been accepted by Huxley[4] but have been criticized by Mayr[5].

Worthington's supposition is that large and vigorous predaceous fishes of the genera *Lates* and *Hydrocyon* which are present in several African lakes have played an important part in restricting the adaptive radiation of the non-predaceous species. In Lake Nyasa, where these genera are not represented, he claims that their place is taken by a much less vigorous type of predator in the form of two species of *Barilius*, and as a result large-scale radiation has been permitted to occur.

The results of recent work by us on the ecology and feeding habits of fishes inhabiting both the inshore regions and open waters, together with the results of the 1939 fishery surveys[6] and the work of Lowe[7], indicate that the restrictive effects of predation are not so important as Worthington suggests, as it is now clear that Lake Nyasa harbours a large number of markedly predaceous fishes, each major habitat
having its complement of predators. Although
difference in degree of predation exerted by *Lat*
and *Hydrocyon* and by the Nyasan predators is n
denied, this is probably compensated for by the gre
numerical abundance of some of the Nyasan specie

Predaceous species of the family Cichlidae inclu
the following: *Rhamphochromis* (at least eight specie
the dentition and diet of which are similar to th
occupied by the pikes of Europe and North Americ
*Serranochromis thumbergi* (Castelnau), *Aristochrom*
*christyi* Trewavas, and several species of *Haplochrom*
for example, *H. kiwinge* Ahl, *H. dimidiatus* (Günthe
*H. compressiceps* (Boulenger) and *H. macroston*
Regan. The non-cichlid piscivorous species inclu
*Bagrus meridionalis* Günther, *Barilius microcephal*
Günther, *Barbus rhoadesii* Boulenger, and sever
species of *Clarias*.

Many of these species feed exclusively or almo
exclusively on fishes except, of course, when ve
young. In addition, many other species living
the Lake can be classed as mild predators which ta
fish as part of their diet. Further, it has been observ
that almost any fish in the Lake, be it carnivore
herbivore, will take the eggs or fry of other fish
whenever the opportunity to do so arises.

Fishes in Lake Nyasa, therefore, do not lead liv
which are relatively uninfluenced by predators
Worthington suggests. On the contrary, the percen
age of predators appears to be extremely high, an
as it is improbable that all the predators represe
the most recently evolved species there is no reas
to suppose that, except perhaps in the very ear
stages of colonization, the Lake has ever been witho
its complement of predaceous species.

The fact that we cannot agree with the suggesti
that the great adaptive radiation shown by t
Nyasan fish fauna has taken place largely becau
of the absence of predators does not mean th
we adopt Mayr's view that the phenomenon ca
be explained on the basis of succession of coloniz
tions from a number of different river systems. Thi
while it may have played some part in the initi
stages of the process can certainly be discounted
an important cause of the state of affairs which exis
to-day. The purpose of the present note, however,
not to propose new theories but to indicate that a pr
viously widely circulated view can no longer be hel

## So-called Endosperm Embryos in *Isomeris arborea* Nutt

In 1937 Billings[1] published a paper on th
reproductive cytology of angiosperms, illustrated b
*Isomeris arborea*. His observations may be sum
marized as follows: (1) this plant is a haploid wit
a complement of 17 chromosomes; there is no tr
meiosis or syngamy; (2) the megaspore mother ce

otions directly without producing the usual gaspores ; (3) the mature embryo sac is 3-nucleate, sisting of two synergids and an endosperm nucleus, ue egg being absent ; (4) there is no fertilization ; the endosperm begins as free nuclear, but soon art of it becomes differentiated into multinucleate icles or nodules ; and (6) the embryo arises as a ot outgrowth from one of the endosperm nodules. 'rom time to time, other embryologists have ressed doubt on the accuracy of these reports and ssed the need for a re-investigation of *Isomeris*[1-4]. recent years Maheshwari and Khan[5], and Mahesh- i and Sachar[6] were able to rectify some of the ors made by Billings. Maheshwari and Khan[5] have arly shown that the megaspore mother cell under- s the normal reduction divisions and forms a ad' consisting of an upper dyad cell and two gaspores. The chalazal megaspore gives rise to 8-nucleate embryo sac of the *Polygonum* type. lings had assumed the absence of an egg cell and formation of the embryo from one of endosperm lules located somewhere in the lower part of the bryo sac. We found a perfectly normal egg cell l an embryo in the usual micropylar position.

A few points remained nevertheless to which a clue s been obtained only recently. These are : (*a*) ether fertilization is really absent ; (*b*) what is nature of primary endo- rm nucleus ; (*c*) what is the e origin and function of losperm nodules, and (*d*) at is it that brings the bryo to the basal part of embryo sac cavity ?

Billings stated : "the endo- rm nucleus in *Isomeris orea* is single in origin and haploid with respect to its romosome complement . . .". is is not true, as we have ind two polar nuclei lying e-by-side in the upper part the embryo sac. Actual ion could not be observed ; t the size and appearance of large central nucleus in any embryo sacs leaves no ubt that it represents the ondary nucleus.

Billings saw pollen tubes in ny ovules, but surmised that sperms were never dis- arged. Fig. 1 here clearly ows syngamy as well as triple ion, and it may therefore concluded that the embryo d the endosperm are diploid d triploid respectively, as is oical of most angiosperms. ice Billings never observed uble fertilization, he wrongly erred that the endosperm is ploid.

The zygote, while still at e micropylar position, under- es a series of transverse visions and forms a long iseriate pro-embryo (Figs. 4). Later, all the cells of e suspensor enlarge con- lerably in size and also become multinucleate (Figs. 8, 9). Their hypertrophied nature suggests a haustorial role. Due to the formation of an exceptionally long suspensor the embryo proper is pushed down in the lower part of the embryo sac. A study of whole mounts of embryo sacs dissected out from ovules was very useful and revealed features which had escaped notice in sections. It is now clear that the long suspensor often becomes coiled and twisted (Fig. 10). In microtome sections this organ is cut up into several segments which appear as multinucleate vesicles imbedded in the free nuclear endosperm. Billings, who had missed both the zygote as well as the young pro-embryo, was led to believe that these vesicles or nodules are derived from the free nuclear endosperm ; and as he saw a close connexion between these vesicles and the embryo proper in the middle part of the embryo sac, he postulated an endospermic origin of the embryo (Fig. 11). It is now evident that these vesicles, which were also provisionally accepted by us as endosperm nodules, are in reality the cells of the massive suspensor and have nothing to do with the endosperm (Figs. 5–7).

Briefly then, contrary to what Billings had said, *Isomeris arborea* follows the usual course of development followed in angiosperms, fertilization occurs normally, and the embryo does not arise from an

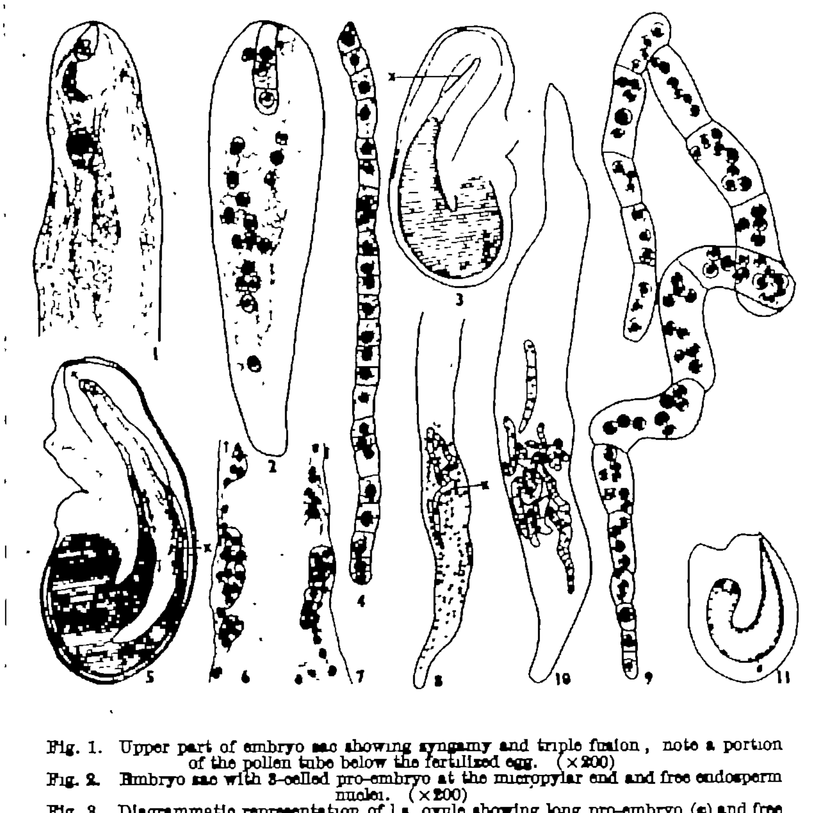

Fig. 1. Upper part of embryo sac showing syngamy and triple fusion, note a portion of the pollen tube below the fertilized egg. (×200)

## Relationships between the Flying Fox (Genus *Pteropus*) and Arthropod-borne Fevers of North Queensland

DURING field investigations by one of us (L. C. R.) there was observed a fairly close relation in season and place with areas of the city of Townsville, North Queensland, Australia, in which an extensive epidemic of dengue fever occurred during the months of December 1953 to March 1954.

The history of past epidemics in Queensland, so far as can be traced, and also observations made by two of us (L. C. R. and J. L. O'C., unpublished) during the course of the 1953–54 epidemic suggested that members of the flying fox genus (*Pteropus*) might well serve as a reservoir from which the virus could be conveyed to regions closely in association with dwelling-places—because of the habit of these animals of swarming, just after nightfall, from their camps, usually in mangrove swamps, to fruit trees surrounding dwelling places, where they would thus come in close proximity with the known vectors in Townsville (*Aedes* (*Stegomyia*) *aegypti* Linn.).

In investigating this hypothesis a collection was made of various species of *Pteropus* in and around the Townsville area in the months of October–November 1954—about two months prior to the usual time of onset of dengue fever. It should be observed th only a few sporadic cases occurred in the city ov the period December 1954–November 1955.

Table 1

| Serial No. | Species | Deaths in mice* | Presence of antibody |
|---|---|---|---|
| *FF* No. 1 | *gouldi* | 0/6 | positive |
| 2 | ,, | 5/6 | negative |
| 3 | *scapulatus* | 5/6 | ,, |
| 4 | ,, | 2/6 | inconclusive |
| 5 | ,, | 3/6 | ,, |
| 6 | ,, | 4/6 | ,, |
| 7 | ,, | 3/6 | ,, |
| 8 | *gouldi* | 4/6 | ,, |
| 9 | ,, | 6/6 | negative |
| 10 | *scapulatus* | 3/6 | inconclusive |
| 11 | ,, | 6/6 | negative |
| 12 | ,, | 6/6 | ,, |
| 13 | ,, | 5/6 | ,, |
| 14 | *gouldi* | 0/6 | positive |
| 15 | ,, | 0/6 | ,, |
| 16 | ,, | 3/6 | inconclusive |
| 17 | ,, | 1/6 | positive |

* The numerator indicates the number of mice dead at the end of the test; the denominator indicates the number of mice inoculated.

Specimens of two species were obtained: sixte of *P. gouldi* and eighteen of *P. scapulatus*. The brai of these were submitted to histological examinatic and heart blood to serological test for protecti antibodies against the virus of dengue fever Type Mice were inoculated with a mixture of equal volum of inactivated undiluted serum and virus suspensi containing 100 mouse *LD* 50. Mixtures were incubat for two hours at 37° C. prior to injection into mice for each serum specimen.

The results of such protection tests are set out Table 1.

Those tests in which five or six mice survived taken as positive evidence of the presence of protecti antibodies, those in which 0 or 1 mouse survives a interpreted as evidence of the absence of antibod Tests in which 2, 3 or 4 mice survived are regard as inconclusive.

Although the challenge virus used was deng Type I (the Hawaiian strain isolated by Sabin), the results are not interpreted as conclusive of pe infection by that virus.

Current work by us indicate that there is a ve close serological relationship between the virus dengue fever (Type I) and of Murray Vall encephalitis.

## A Variable Dosage Sprayer for Agricultural Experiments

THE present method for testing in the field t toxicity and selectivity of herbicides or other spr chemicals necessitates spraying a number of separa plots with different dosages. Valuable time is wast in making up solutions and emptying the sprayi machine between operations. The time required longer the closer the gradations of dosage which it considered necessary to examine. We have design a machine which makes it possible with one filli to spray continuously decreasing concentratior starting from an arbitrary upper limit. A who spectrum of results is thus made available for exa ination in far less time than is consumed in getti less complete results by the established method.

The dilution principle used is to pump liquid the spray nozzles from an intermediate vessel whi is otherwise closed except for a lead tube from water-supply vessel, is equipped with an efficie agitator and is initially completely filled. As spr liquid is withdrawn it is replaced by water and t concentration falls in an exponential manner. coarsely porous plug in the entrance tube of t mixing vessel prevents adventitious dilution. T nozzles are carefully selected to have equal outp at a given pressure, and are fed by separate narro polythene tubes of equal length from a comm manifold as close as possible to the pump, that the same concentration reaches all nozzl simultaneously.

The pump is directly geared to the tractor on which the machine is mounted, and therefore the concentration taken into the pump is an exponential function of distance along the plot. Since it is necessary for air to be expelled from the spray system before the plot is reached, the simple principle above described is modified by providing also a direct tube from the water tank to a three-branch cock immediately above the pump. The tractor is driven towards the plot spraying water only, pumped through this line. The cock is then quickly thrown over and spraying of chemical commences. Owing to residual water in the pump and manifold, the concentration at the spray nozzles, after clearance of the tubes to the nozzles, rises steeply to a concentration somewhat less than that initially charged, before decreasing along the remaining length of the plot in an approximately exponential manner. The concentration is uniform across the plot. The form of the curve can be worked out theoretically from the volumes; but results are based on experimental calibration. The experimental curve is very accurately constant over the range of speed of a tractor working in one gear. Since the machine is effectively self-washing, repeated sprayings with the same or different chemicals can be made very rapidly.

The machine has enabled the expected advantages of speed and continuity to be obtained, and in addition provides a means of obtaining a rapid estimation of selectivity, and the dosage ratio for limiting crop-damage and limiting weed-kill. Changes in apparent effect with time are also easily observed. By filling throughout with the same spray liquid, the machine can be used for normal spraying. It is also possible to use the machine for examining the effect of admixture of herbicides or of a herbicide and an ancillary (for example, wetting) agent in continuously varying ratio. The exponential form for one concentration or ratio is not, however, the most satisfactory for this application, and a modified machine, using two mixing tanks in series, which gives a sigmoid concentration–distance curve, is to be preferred.

Our thanks are due to Mr. A. Ross for construction of the machine and to the directors of Fisons Pest Control Ltd. for permission to publish this account.

## Live Coelacanths

From the discovery of the first Coelacanth at East London in 1938, it was my aim not only to discover their true home, but also I hoped to live to see a living Coelacanth, and for mankind generally to be able to see this living link with the incredibly remote past. When *Malania* was found at the Comores, I planned to catch Coelacanths alive and to keep them alive. It is therefore gratifying that the French are plainly making every endeavour to achieve this. The article by Prof. J. Millot in *Nature* of February 26, 1955, on the experience of the first living Coelacanth at the Comores is of special interest.

The failure of the French to keep their fish alive for more than a few hours is attributed by them to decompression combined with rise in temperature of the water, while a high degree of photophobia on the part of the fish is alleged. While there may be something in this, in my view the cause is probably quite different. Prof. Millot and his collaborators are possibly not aware of the experience that large fishes taken alive after a struggle on a line even with no visible laceration rarely live long after, certainly not in aquaria, and even when liberated many die very shortly. Curiously enough, fishes taken by harpooning, even when extensively gashed, show a greater survival-rate than those taken on hooks. Coelacanths caught by net or trap and kept in a closed vessel will almost certainly have a greater chance of survival even at normal pressure.

It is doubtful whether the view about decompression or small variation in temperature is tenable, since after being hauled to the surface in a trawl-net near East London, the first Coelacanth lived for more than three hours, out of the water, on the deck of a trawler on an unusually warm day.

It is interesting to note that the French used a boat as an improvised aquarium. At a meeting in Nairobi in October 1953 I suggested a decked boat, since it seemed likely that an important factor in survival would be to shield the fish from shocks until such time as it could become accustomed to a new environment. An open whaler, however, was used at Matsumudu, so that the fish had a clear view. We are told that "Throughout the night, which the delighted population of Matsumudu passed in singing and dancing to celebrate the capture, the Coelacanth was watched over with admirable care", by officials, doubtless with constantly flashing torches, and only those who have experienced a night such as is indicated here can have any idea of the noise and lights: the Coelacanth at Matsumudu must have passed the night in a state of high nervous tension.

What the French considered 'photophobia' on the part of the Coelacanth is, in my view, no more than the natural uneasiness that any large and intelligent fish would experience as unfamiliar surroundings and objects become increasingly obvious from dawn.

The 'luminescence' of the eyes of the live Coelacanth is interesting. This phenomenon is, however, quite common in sharks and other large fishes of shallow waters, and on this night there was bright moonlight.

It is a notable feature of the reports that the depth to a metre at which each Coelacanth was caught has been stated. As all these were apparently taken by natives fishing from drifting canoes at night, and the slope of the bottom offshore at the Comores is stated to be at least 50°, it would be of general interest to know how this high order of accuracy is achieved.

In the matter of the first egg-bearing female Coelacanth, it is a strange coincidence that this was captured by one of the crew of Captain Hunt's vessel. only a short distance from where this was anchored. (It was Captain Hunt who took our Coelacanth leaflets to the Comores, which resulted in the discovery of *Malania* there.) The fish was apparently cut open and seen to contain a cluster of eggs at all stages of development "such as is observed in a fowl", or in oviparous sharks. We may therefore expect Coelacanths to have egg-cases like those of Elasmobranchs.

# FORTHCOMING EVENT

## Sunday, September 4—Wednesday, September 7

British Association for the Advancement of Science (at Bristol).—Continuation of Annual Meeting.

**Sunday, September 4**

At 11 a.m.—(in Bristol Cathedral)—Religious Service. Preacher: the Rt. Rev. the Lord Bishop of Bristol.

At 8 p.m.—Prof. H. D. F. Kitto: "Scientific and Dramatic Modes of Thought".

**Monday, September 5**

At 10 a.m.—Mr. W. N. Edwards: "Geographical Distribution of Past Floras" (Presidential Address, Section C).

At 10 a.m.—Dr. R. S. Creed: "The Sensory Pathway" (Presidential Address, Section I).

At 8 p.m.—Mr. R. J. C. Atkinson: "Stonehenge in the Light of Recent Research".

**Tuesday, September 6**

At 2.30 p.m.—Mr. B. J. Mason: "Man's Influence on the Weather: Recent Progress and Future Possibilities" (Special Lecture for Young People).

# APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Physicist (Basic grade) at the Regional Radium Institute, Bradford—The Secretary, Royal Infirmary, Bradford (September 12).

Tutor in Geography—The Registrar, The University, Liverpool (September 12).

Scientific Officer (with an honours degree in chemistry) for scientific control and development at Northern Outfall Works, Beckton, E.6—The Medical Officer of Health (PH/D1), County Hall, London, S.E.1 (September 14).

Lecturer in Pharmacology at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (September 15).

Physicists and Mechanical Engineers (with a first- or second-class honours degree in physics or mechanical engineering, and preferably with some understanding of aerodynamics) at the Royal Aircraft Establishment, Farnborough, Hants, for research and development mainly concerning engineering, instrumentation and problems of parachute development and application, vulnerability of aircraft, refrigeration and air conditioning—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.304/5A (September 17).

Senior Research Officer or Research Officer (with a university honours degree in science or fuel technology) in the Coal Research Section, Commonwealth Scientific and Industrial Research Organization, North Ryde, New South Wales, Australia, to participate in the studies being undertaken to evaluate combustion characteristics of Australian coals—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting 480/154-2 (September 24).

Lecturer or Assistant Lecturer in Metallurgy—The Registrar, The University, Leeds 2 (September 26).

Assistant Lecturer in Dairy Bacteriology—The Registrar, University College of Wales, Aberystwyth (September 30).

Lecturer in Mechanical Engineering—The Registrar, College of Technology, Manchester 1 (September 30).

Junior Research Fellow (with a physics degree) in the Instrument Technology Section of the Physics Department, for photo-electronic research—The Professor of Instrument Technology, Imperial College of Science and Technology, London, S.W.7 (October 1).

Society for Analytical Chemistry Research Fellow (with at least an honours degree or A.R.I.C., and with experience in analytical chemistry) in Analytical Chemistry, for work concerned with the determination of elements by means of radiochemical methods—The Secretary of the Analytical Methods Committee, The Society for Analytical Chemistry, 7–9 Idol Lane, London, E.C.3 (October 1).

Chair of Cultural Anthropology at the University of the Witwatersrand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, October 10).

Lecturer in Philosophy at Auckland University College, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, October 15).

Lecturer in Physics at Victoria University College, Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, October 15).

Chair of Engineering at the University of Tasmania—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Tasmania, October 30).

Senior Lecturer in Bacteriology and an Assistant Lecturer in Bacteriology at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong, October 31).

Assistant Experimental Officer (with at least G.C.E. (advanced level) or intermediate B.Sc. with mathematics) as Assistant to Statistician, for computational duties and some photographic work—The Director, Anti-Locust Research Centre, c/o British Museum (Natural History), Cromwell Road, London, S.W.7.

British Steel Castings Research Association Fellow (graduate, with some research experience) to work under the direction of Dr. T. P. Hoar in the Department of Metallurgy at Cambridge University, on problems relating to steel castings—Dr. T. P. Hoar, The Department of Metallurgy, Pembroke Street, Cambridge.

Chair of Physiology at Makerere College (University College of East Africa)—The Secretary, Inter-University Council for Higher Education Overseas, 1 Gordon Square, London, W.C.1.

Group Leader (Nuclear Physics Branch) to develop specialized electronic circuits for nuclear physics research in an expanding Branch whose facilities include a 6 MeV. Van de Graaff generator and other accelerators—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berkshire, quoting Ref. 747/34.

Technical Officer (qualified chemist) to act as Secretary to committees preparing standards in the chemical and related fields—The Establishment Officer, British Standards Institution, 2 Park Street, London, W.1.

# EDUCATIONAL POLICY AND MAN-POWER

THE debate on scientific and technical man-power in Great Britain which was initiated by r. Austen Albu in the House of Commons on July 1 added little to the observations on that subject hich have since been published in the report of the dvisory Council for Scientific Policy. The debate as noteworthy, however, for the way in which it elated the man-power situation in Britain to ducational policy as a whole, and it also elicited rom the Minister of Education a statement as to ducational policy, and particularly the policy he nvisages for technical education. Much that Sir avid Eccles said was fundamentally sound, and the ull statement which he promised to make before hristmas will be awaited with great interest. The ery fact, however, that Sir David Eccles confined imself, on this issue of scientific and technical manower, to the expansion of technological and technical ducation, and left the question of university educaion to be dealt with by the Financial Secretary to he Treasury, emphasizes the unhappy division which as been responsible for so much frustration and utility in the past.

Neither Sir David's speech nor that of Mr. Henry rooke gave any indication that this position is to be emedied, and Sir David's rather lame attempt in lefence of his recent acceptance of the recomnendation in the report of the National Advisory ouncil for Education for Industry and Commerce or the institution of a new award for technology lamps hopes of a new and vigorous policy which his peech might otherwise have raised. There is little ndication that the real issues are appreciated, and esources and effort will apparently continue to be listributed too widely or frittered away on nonssentials instead of being concentrated where they vill be most effective. Sir David rightly emphasized hat we should not expect to expand the output of cientists and technologists or technicians cheaply; ut he has equally pointed out the necessity of careful election and timing in order that our limited resources nay be expended to the best advantage. That canot be done without a clearer conception of the elation between technological and technical and niversity education than was shown by the Governnent speakers in this debate. The Minister fully ecognized the human aspect of the problem and hat it is not a matter merely of providing facilities: t is also a matter of persuading more boys and girls o continue their education in particular ways and to adopt particular careers. The creation of a favourble public opinion is a most important factor in ecuring the conditions which will induce boys and irls to adopt the careers which the public interest t any particular time demands, whether it be as cience teachers in the schools, as teachers of techology in the colleges of technology or the univerities, or as technicians and technologists in industry r the public corporations or State departments hemselves.

This is a matter which calls for close co-operation, not merely between industry and the colleges of technology and technical colleges, but also with the secondary schools and the universities and university colleges. The bias against a career in industry or technology is only likely to be removed when the value of technology as an intellectual discipline itself is fully recognized within as well as without the universities. This is an essential factor in inducing a sufficient number of the ablest students to adopt a career in applied science and in attracting to the colleges of technology teachers of outstanding ability. The real objection to the proposed new award is that it does nothing to help the colleges of technology or the technical colleges to gain the status that alone will give the award any value. It ignores the extent to which the professional institutions already provide hallmarks of proficiency, and may well divert effort which could be better expended in creating the teaching conditions and facilities likely to attract teachers of the necessary calibre.

It was clear from Sir David's remarks here that he did not appreciate the importance of academic autonomy as a condition of obtaining staff of the highest qualifications and ability for selected colleges of technology, nor that the number of such men and women is too limited to hold out any real hope of staffing twenty, let alone thirty, colleges of technology on the scale necessary. Sir Hugh Linstead, indeed, questioned the practicability of so staffing more than half a dozen colleges. While, too, there can be no doubt as to the importance of securing the full interest and support of the local authorities, the Minister's view that the colleges of technology selected for development as regional centres cannot therefore be independent of local control is open to challenge. The surrender by the Manchester City Council of its share with the University in the administration of the Manchester College of Technology on the grant of the Royal Charter to the College shows that local authorities may well possess more vision and judgment than the Minister allows. This new charter provides for the setting up of an independent board of governors appointed by interested bodies and, seeing that the Royal Charter has been granted at the request of the Manchester City Council, the University of Manchester and the County Councils of Lancashire and Cheshire, it is inconceivable that academic autonomy will mean any diminution of local interest or pride. Much of the introductory teaching hitherto done at the College will in due course be transferred to other technical colleges in the neighbourhood, leaving the College of Technology as a centre for advanced teaching at degree standard, for training postgraduate students in several branches of technology and for research in these fields. Sir David Eccles himself contemplated this transfer of functions from the regional colleges, and his indifference to academic autonomy and to the views of the professional institutions may well be a direct consequence of the division of responsibility which leaves university education to the Chancellor of the Exchequer, acting through the University Grants Committee. The need for transferring the responsibility for higher technological education fairly and squarely to the University Grants Committee, or alternatively for creating, as Sir Robert Robinson has been the latest to suggest, a technological grants committee, acting in close co-operation with the former body, but independent and with adequate financial appropriations, could not be better demonstrated.

Nor might this change alone suffice. To remove the responsibility for technical education entirely from the Minister of Education might be too disruptive; but the close relation between technical and technological education, and between the latter and university education, makes it imperative that policy in these fields should not be determined without review at a level high enough to take full cognizance of national needs in respect of scientific and technical man-power. In the existing structure, the Lord President of the Council, with his responsibility for the Advisory Council for Scientific Policy and for the various research councils, seems to be the appropriate Minister, particularly in view of the increasing extent to which the Department of Scientific and Industrial Research is concerned with technical education. The importance of the issues, however, are such that not only should the Minister be provided with an appropriate staff, but also the argument for his being a member of the House of Commons is as cogent as that which requires the Chancellor of the Exchequer to be a member of that body. No Government which is content to allow the Lord President to be answerable to the House of Commons at second-hand through a Treasury spokesman can fairly claim to recognize the over-riding importance of science and technology in Britain's economy to-day.

These issues apart, there was much to welcome in Sir David Eccles's speech of July 21. He not only emphasized that the removal of the critical shortage of scientists and technicians is largely a matter of public education rather than administration—of firing the imagination of school children, their parents, teachers and employers, with the adventure of the scientific revolution; he equally insisted on the importance of general education—of giving better education in all subjects and not just in science and mathematics. The first step is to raise the standards of education in the infant schools, primary schools and secondary schools. Teaching men and women how to enjoy wealth is as important as teaching them how to produce it.

Concluding the debate for the Government, Mr. H. Brooke stated that the Chancellor of the Exchequer has sanctioned a further one million pounds for university development schemes in higher technological education next year. This would virtually complete the programme proposed last year by the University Grants Committee and bring the total Government grant for building schemes outside London to about £4,350,000, which would be increased by equipment and other costs to about £6 million and would necessitate an extra £520,000 for maintenance. Major schemes would be starting in the immediate future in Birmingham, Newcastle on Tyne, Sheffield and Cambridge, and a further set of projects, now in the planning stage, constituted the 1956–57 programme to start at Cambridge, Newcastle on Tyne, Sheffield, Southampton and the Manchester College of Technology.

As regards the Imperial College of Science and Technology in London, expenditure on which in 1953–54 exceeded £1 million, of which almost three-quarters came from the University Grants Committee, Mr. Brooke stated that building work to the value of £4 million has already been authorized, and the developments are expected to cost in all £15 million. The academic staff has already increased from 220 in 1952–53 to 304 in 1953–54 and full-time students from 1,653 to 1,870. While the release of the whole of the South Kensington site involves more formidable difficulties than had been originally appreciated and enabling legislation may be required, neither building work nor academic expansion is being impeded.

Mr. Brooke also pointed out that in the academic year just ended the increase in full-time students of technology and science has accounted for almost the whole of the increase in full-time university students, and he estimated that the number of graduate scientists in the working population of Britain has risen from less than 50,000 in 1939 to nearly 80,000 to-day; for technologists the increase is probably from about 50,000 to more than 130,000; and making no allowance for the expansion of facilities at the universities and technical colleges now in hand, these figures should increase by 1965 to more than 110,000 scientists and about 225,000 technologists. Out of 80,000 scientists, about 25,000 are estimated to be employed in teaching and 10,000 in the Civil Service and allied establishments, about half of whom are in the Defence departments and the Atomic Energy Authority. There are also about 3,000 young post-graduate research workers, and apart from some scientists in the Armed Services, the remaining 40,000 are in industry.

Although these figures were given at the end of the debate, they were obviously known to Sir David Eccles when he said the expansion of the universities would still provide too narrow a route to give us the numbers required, both to push forward the frontiers of science and engineering and to apply them to public service. We must therefore shape the education system of Britain, he said, to supply a very large number of trained men and women in support of the scientists, and for these a much broader route is required than that leading to a university degree. To achieve this he suggested that at all stages there should be young people leaving the local technical colleges and advanced technical colleges for industry and young people coming to the colleges from industry. This would involve a very close partnership between the education authorities and industry, particularly in developing the sandwich courses which the Minister regards as so promising. Moreover, he emphasized that it is equally important not to neglect he arts and the humanities; we cannot stop the cientific revolution, but it is equally important that men should learn to behave well. There is also a hortage of artists and humanists and men who put piritual values first, and the educational system must seek to supply these as well as to meet the eed for scientists and technicians.

Although the Minister's speech was criticized for not stressing sufficiently the question of quality in elation to science teaching, either in the schools or he technical colleges, and his proposal to institute new award for technology had a very mixed reception, on the whole his speech was welcomed by the House, which had clearly been deeply impressed by Mr. Albu's remarks on the extent of the actual hortage of scientists and technologists. Mr. Albu had emphasized particularly the implications for the demand for scientific and technical man-power of the development of nuclear energy, the gasification of coal, the modernization of transport, and the needs of the under-developed territories, not only in respect of research, but also, as Sir Ernest Oppenheimer has recently stated, the grave shortages of qualified men in South and Central Africa at all levels and in nearly all industries and Government departments. Mr. Albu's own suggestions, however, notably in egard to the need for ensuring that there is no waste in the use of scientific man-power and that one senior Minister should be made responsible for eviewing the whole problem in the light of changing needs and the present provision for meeting them, met little response in the debate.

One satisfactory feature of the debate is the ndication it gives of the extent to which the House of Commons has been impressed by the seriousness of the situation, and the importance of looking at education at all levels and the problem of trained man-power as a whole. Sir Alexander Todd's remarks o the Parliamentary and Scientific Committee as to he need for eliminating the feeling that science, and till more technology, are socially somewhat inferior pursuits, for seeing that children at school are made more aware of the attractions of a career in science, and for reducing premature specialization at school had obviously convinced the Minister and many members on both sides of the House. There was also upport for his view that no man can to-day claim o be educated if he knows nothing of natural science, and that besides relieving the shortage of science eachers a general university degree in science would be a more effective means than now exists for producing the men and women with an awareness of science who are needed in all walks of life.

Another important feature of the debate was the general recognition that the shortage of science teachers and the expansion of university and of technological education are only particular aspects of education policy as a whole, and that they are closely related to primary and secondary education. There are, in fact, already facilities for technical training, for example in engineering and in textile technology, which are unused because sufficient young people cannot be persuaded to undertake such studies. On the other hand, there are fields where the number of young people who can be trained is limited by the buildings and facilities that are available; and although the climate of opinion is undoubtedly changing towards careers in science and technology, much remains to be done before existing facilities, and still more the expanded facilities corresponding with Britain's real needs, are fully used.

It is at least encouraging to find that the right questions are at last being asked in Parliament, even to the extent of whether we have the right departmental organization for linking the educational needs of the nation with the actual policy being pursued in universities and technical colleges and by local authorities. The importance of quality and of academic autonomy, the impossibility of developing educational institutions at any level 'on the cheap', the necessity for an overall view and for relating educational policy both to available resources and to the age-structure of the population as well as to the changing needs of the Commonwealth, are clearly appreciated far more widely; and to some extent these needs are over-riding preconceived ideas and party prejudices. Perhaps a greater awareness is needed that a technical college, like a university, is an organic entity, and that it needs a tradition of teachers as well as students if it is to function wel and realize the ideals which, very clearly, many of its principals as well as teaching staff already cherish. That ideal of a balanced education, which turns out experts not merely technically competent but also leavened with imagination and human understanding, will not be achieved simply by more generous support for the technical colleges and the universities. Its fulfilment requires also an educational policy which attempts in the schools themselves to feed the colleges and universities with students whose general education is such that it provides an increasingly effective basis for their further education as professional or technical specialists.

# MECHANISMS OF DEVELOPMENT

## Analysis of Development

Edited by Prof. Benjamin H. Willier, Prof. Paul A. Weiss and Prof. Viktor Hamburger. Pp. xii+735. (Philadelphia and London: W. B. Saunders Company, 1955.) 105*s*.

THIS massive volume is one of the most magnificent contributions which American learning has made to the biological sciences for many years. Its aim is nothing less than "to present a modern synthesis of our knowledge of the principles and mechanisms of development". This is a task which has not been attempted, at least in such a detailed fashion, since Schleip's monumental "Die Determination der Primitiventwicklung" of 1929. More recent authors who have given discussions of comparable thoroughness have confined themselves either to particular aspects of the subject, as Needham, Brachet and Barth have dealt with the biochemical mechanisms, or to certain particular groups such as the echinoderms and amphibia in Lehmann's excellent book. The American authors, however, have covered the whole range of experimental embryology in the broad sense.

"It was evident from the start," the editors write, "that the subject matter had grown in volume and intricacy to the point where it seemed futile for any one individual to attempt to cope with such a task." A short browse through the various chapters will convince even the most self-confident reader that this is true, in the sense that no one man could nowadays possess a critical mastery of all the fields which are included. The battery of experts which has been got together to produce this compilation of knowledge is extremely impressive, and it is seldom one comes across a field which has had to be dealt with by an author who has not made important personal contributions to it. Nevertheless, there are inevitably certain losses to be set against the great advantages which such expertize brings. The editors very disarmingly recognize that "much of the desired unity and integration would be sacrificed, and the present volume bears plainly the stigmata of these imperfections". As a matter of fact, they are too modest. The work is extremely well edited; the individual contributions fit neatly together, with few omissions or overlaps. If the book is to be criticized, it is not for lack of unity or integration at its own level of treatment, but for the absence of a general theoretical scheme which might, as it were, lie behind the details cited in each chapter and provide a framework into which they fitted. Only a single individual author could provide such a scheme, and probably he would have himself to select and arrange the detailed facts which would illuminate it. In spite of the magnitude of the field, there would seem to be, therefore, a place for people bold enough to attempt at least to comprehend, if not to master, the whole of it.

The nearest approach to such a general synthesis is the first chapter, on "Problems, Concepts and their History", by J. M. Oppenheimer. This is a fascinating account of the history of 'embryological philosophy', and one begins to hope that the author will carry on right to the present day, and give us a summary of the ways in which active experimentalists are now picturing to themselves the embryos which they are studying. Alas, she brings her story to a close at about the time of Spemann, and leaves us only with the hint that "the greatest progressive minds of embryology have not searched *for* hypotheses; they have looked *at* embryos". This shirks the crucial issue of to-day, when we are beginning to feel convinced that it is no longer profitable to 'look' at the embryo by anatomical procedures. We seem to be faced with the apparent alternatives of examining it biochemically, or in terms of genetics, or of cell physiology. Which is the more profitable in the immediate future? Or can they be brought together into one broad-fronted line of advance? We are given no direct answer. But the three individual approaches are each separately discussed. F. O. Schmitt and H. Ris contribute extremely stimulating accounts of cell constitution and division. Steinbeck and Moog give a highly schematized description of cell metabolism, the merits of which I am not qualified to judge. O. Stern discusses gene action in a chapter which, to my mind, is somewhat too influenced by the pre-occupation of geneticists with the question of what a single gene does rather than with the embryologist's problem of how the development of an organ or tissue is influenced by its genotype; it thus overlooks what is perhaps the most important contribution of genetics to embryology, namely, the demonstration that even the simplest developmental process is influenced by an extremely large number of factors.

Of the more conventionally embryological chapters, those by Holtfreter and Hamburger on the Amphibia, Weiss on the nervous system, and Burns on the urogenital system are perhaps outstanding; but there is much else which is first class. The only topics the treatment of which seems seriously inadequate are the insects and the whole problem of the formation of pattern and shape; and one might wish for a fuller account of the recent work of the Swedish school on mitochondria and enzymes in echinoderm embryos. A considerable part of the book is devoted to the later stages of development, which have been passed over rather lightly in most texts.

It is unfortunate, but probably inevitable, that the size of the work will put it out of the financial reach of most individual workers. It is an absolutely essential requirement for all libraries which wish to keep up to date in general biology.

C. H. WADDINGTON

# RESOURCES OF THE SEA

## The Inexhaustible Sea

By Hawthorne Daniel and Francis Minot. Pp. 239 + 25 plates. (London: Macdonald and Co. (Publishers), Ltd., 1955.) 16*s*. net.

IN the search for further supplies of food for the world's growing population, some attention has been directed to the sea as a potential source of these requirements. The authors of "The Inexhaustible Sea" contend that the sea can do much to meet this need, and can in addition be a valuable source of minerals which are becoming progressively more scarce on land.

Much of this book is a straightforward and very readable account of the exploitation of the sea, from the earliest fishing methods to modern trawlers and whaling factory ships. The beginnings of the science of oceanography are described, together with chapters on the chemical and biological constituents of the sea, food relations in the plankton, and modern fishing and whaling methods. A chapter on new instruments for studying the sea perhaps pays too much attention to echo-sounders and their uses, leaving a mere couple of pages to other methods of research, but in general the authors have covered their subject adequately.

Opinions may differ, however, as to the extent to which the oceans can contribute to man's food requirements. It is true that much progress can be made in improving fishing methods, in the farming of enclosed sea areas, and in the preservation and marketing of fish. But how far will these go towards solving our food problems? The greater part of the globe is covered by sea, but at present only certain areas, mainly on the continental shelves, can be fished economically. In the deep oceans, nutrients are lost from the productive surface layers by the sinking of dead and decaying organisms to deeper layers, and it is only in certain areas where there is upwelling of deep water that nutrients are returned to the surface. In tropical waters the very diversity of species, few occurring in the large shoals found in temperate regions, makes productive fishing more difficult. Much could be done to popularize the less common species of fish as food: the authors emphasize that only a very few types of fish are to-day widely exploited by commercial fisheries.

Overfishing, a very real problem in certain areas like the North Sea, is given scant attention in this book; and while it is no doubt true that the total production of fish, if it could be exploited, would more than suffice for man's requirements, much of it is not available either because it is in the deep oceans where existing fishing methods are unsuitable, or it is too remote from centres of human population to be harvested economically. Fisheries research has much to contribute to the problem; the sea may be inexhaustible, but is exploitation of the sea on the scale envisaged worth while? Cultivation of the vast barren and desert areas on land would seem to be a more direct and rewarding answer. This book, originally published in the United States, is attractively produced, and is illustrated by some excellent black-and-white photographs. NORMAN HOLME

# THEORY OF THE SOLID STATE

## Quantum Theory of Solids

By Prof. R. E. Peierls. (International Series of Monographs on Physics.) Pp. viii+229. (Oxford: Clarendon Press; London: Oxford University Press, 1955.) 30*s*. net.

ABOUT twenty years ago when the application of wave mechanics to the theory of the solid state had been investigated in some detail, it appeared that basically all relevant problems except superconductivity had been solved. This stage of the theory bears its fruit now in connexion with many important applications. Many aspects of theory itself based on the earlier pioneer work are being developed at present in minute details. Much of this work, unfortunately, does not appreciate that the theory in its present stage is based on a number of assumptions, and that it has not been possible, so far, to justify all these assumptions in a satisfactory way. It is for this reason that recently a renewed interest in the basic side of the theory of solids has arisen. The difficulties which one faces in this connexion are typical for systems of very many degrees of freedom and are similar to some of the difficulties met in other branches of physics.

In these circumstances it is desirable to have a book which describes the present development of the theory in a simple way without going into too great details, but which clearly points to the assumptions on which the present theory is based. R. E. Peierls's recent monograph fulfils these requirements in an excellent way. The book is divided into eleven chapters, the first three of which deal with atomic vibrations and related processes, whereas the remaining eight chapters are devoted to properties of electrons. A number of subjects, in particular those connected with mechanical and electric strength and with crystal structures, have been omitted from the book; but most of the other important questions are treated, though not all in equal detail. This was necessary in order to restrict the size of the book to about two hundred pages, and the choice of the branches which are treated in some detail must naturally depend on the interest the author has taken in their development. Thus, general questions of electrons in perfect lattices, transport (including heat conduction) and magnetic phenomena are presented more thoroughly than questions of cohesive forces or of the interaction of electrons with light. Even so, the author has found space to impress on the reader the importance of certain effects which are often ignored. This holds, for example, of correlation between electrons, the possible significance of which for optical properties is mentioned, though this has never been properly investigated in the literature. A separate chapter deals with the recent attempts to solve the problem of superconductivity on the basis of the interactions of electrons and lattice vibrations. Both the early success and the later difficulties of this theory are well presented. Recent work on so-called plasma oscillations, which one hopes will help in the treatment of the Coulomb interaction between electrons, has not been included in the book.

The book is mainly addressed to theoretical physicists in so far as it assumes knowledge of the basic methods of quantum mechanics. However, the mathematical treatment is very simple in most chapters, so that the book can be read with profit by the experimentalist who wishes to be instructed on the basis of the models which he is accustomed to use. It is hoped that the book will find a wide circulation, and perhaps sometimes will induce research workers to think before embarking on vast calculations. H. FRÖHLICH

# HIGH-SPEED AERODYNAMICS

## General Theory of High Speed Aerodynamics

Edited by W. R. Sears. (High Speed Aerodynamics and Jet Propulsion—Vol. 6.) Pp. xiv+758. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1955.) 100*s*. net.

THE present work is Vol. 6 in an ambitious project published by the Princeton University Press in the United States and by the Oxford University Press in Britain under the general title of "High Speed Aerodynamics and Jet Propulsion". The whole work is to be completed in twelve volumes and is to cover the related fields of gas dynamics, aerodynamics, combustion and jet propulsion. The editorial board which is responsible for the general supervision of this work consists of Theodore von Kármán, Hugh L. Dryden and Hugh S. Taylor. The work has been in progress for some years and, in fact, the formal establishment of the Aeronautics Publication Program took place at Princeton University in the autumn of 1949. In this connexion it may be as well to mention one minor criticism of this great and important work, namely, it is sometimes a little difficult to determine the date on which the different contributions to this volume were completed, and therefore difficult to know exactly how recent is the information which is presented. Another comment which is suggested by the fact that this volume, numbered 6 in the series, is the first to be published, is that the present volume is not self-contained and there are references to work which is to be published in Vol. 3; for example, Crocco's stream function is referred to in the present volume, but the reader is referred to Vol. 3 for a formal definition of this important concept. Questions of priority of publication and discovery are not considered in this treatise, which indeed makes no pretence of being absolutely complete. Considerations of space themselves have set an inevitable limit to the amount of work which is included.

Having made these few critical comments, the reviewer would like at once to pay tribute to the great value and importance of this project. It will provide the aerodynamicist and the aeronautical engineer with what is almost an encyclopædic account of the basic information which has been obtained in the past ten years or so in this most fascinating and vitally important subject; and it will incidentally be of great benefit to the individual research worker, who will be able to throw away some dozens, if not hundreds, of offprints and government reports, now that he has the admirable summaries and critical appreciations which are contained in this volume.

Seven authors have contributed to this volume, which is edited by W. R. Sears. Von Kármán writes on the foundation of high-speed aerodynamics, Friedrichs on mathematical aspects of flow problems of hyperbolic type, Sears on small perturbation theory, Heaslet and Lomax on supersonic and transonic small perturbation theory, Lighthill on higher approximations in both subsonic and supersonic flow; Kuo and Sears have collaborated in a chapter on plane subsonic and transonic potential flows, while Ferri has written two chapters, one on the method of characteristics and one on supersonic flows with shock waves.

The introductory section by von Kármán gives a general account of the linearized theory of aerodynamics, with especial reference to its limitations. This chapter also contains a general introductory sketch of fluid dynamics in the hypersonic range and in the transonic range. The next chapter, by Friedrichs, is almost entirely concerned with problems of the mathematical theory of the differential equations of unsteady one-dimensional flow and of two-dimensional steady flow. Friedrichs gives a careful analysis of what is required in order that these problems should be correctly set, and of the validity of the various idealizations which are contemplated in the mathematical theory.

After traversing the familiar ground of the small perturbation theory due to Prandtl and Glauert, Sears describes the slender-body theory of Munk and Jones and gives a brief review of unsteady flow problems.

These introductory sections cover about 120 pages, and we now come to a long section by Heaslet and Lomax, which occupies about two hundred pages. This chapter opens with a discussion of the wave equation and of some methods of solution. The authors concentrate on the method due to Volterra, although the work of Hadamard is referred to later. They then proceed to discuss standard methods for dealing with problems of two-dimensional steady flow and of three-dimensional steady flow. There is a most useful collection of formulæ and a discussion of the singular integral equations which arise in this part of the subject. In practice, the 'null' transforms which are needed to solve the singular integral equations seem to be obtained by intuition rather than construction. These theories are applied to a number of inverse problems and also to generalized conical flow. The authors then discuss axially symmetric supersonic steady flows and point out the interesting duality between the expressions for the drag of a body of revolution and for a wing of finite span. This is followed by an excellent chapter on slender-airplane theory and by another chapter on the theory of unsteady lift. In this chapter the indicial functions which are fundamental to the topic are quoted but not derived. There is, however, a discussion of the evaluation of the starting lift coefficient which will probably be found more illuminating than in the original paper in which it was first announced. The next chapter deals with reciprocity relations based on Green's reciprocal theorem and on reverse flow theorems. This great section closes with an account of small perturbation theories and transonic and hypersonic flows.

The next section, by Lighthill, covers about 140 pages and deals with the difficult and important problem of obtaining higher approximations to the non-linear equations of fluid dynamics. Although it is invidious to single out for especial mention any one section in this excellent work, it does seem to the reviewer that this is probably the most important section of the whole volume. Lighthill not only gives a very complete and critical account of the older second-order theories of subsonic and supersonic flow, but also gives a stimulating account of the recent work by Whitham himself on the nature of the flow pattern at great distances from an aerofoil or missile. Of all the sections of the book, this one seems to stand out by reason of its continuous appeal to physical concepts and to the new mathematical methods introduced.

In the following section, Kuo and Sears give an account of the hodograph theory due to Chaplygin, together with its simplification by Kármán and Tsien, and to the important, fairly recent developments by Lighthill and Cherry. The ninety-odd pages of this chapter flow with the most valuable summary of formulæ embodying the main properties of the hypergeometric functions which are employed in the solutions of the hodograph equations.

The following chapter, by Ferri, gives a masterly account of the method of characteristics both in two-dimensional potential flow and in axially symmetric flow, while further chapters show how proper allowance can be made for distributed vorticity and for extensions to problems involving three independent variables. Finally, the author discusses the linearized characteristic equations in which one of the velocity components or its variation can be considered small. As a natural sequence, in the concluding chapter Ferri discusses the general theory of shock waves in two-dimensions and in axially symmetric flow; and then passes on to discuss the same problems in transonic flow and in conical flow. These chapters will be most useful to all those who are engaged in the numerical solution of supersonic problems. There is one sentence on p. 587 which reads very strangely, in which Ferri says that "the velocity of sound *a* for the general case depends on the direction of the line along which it is computed". This should be read in conjunction with the careful analysis which Lighthill has given of the physical significance of the fundamental equations, and in particular in connexion with the basic relations, numbered 5 and 6, which Lighthill gives on p. 347.

The publication of this volume is the most important event in the world of aerodynamics since that of the volumes on high-speed flow under the general title of "Modern Developments in Fluid Dynamics" (Clarendon Press, Oxford, 1953). There can be no doubt, too, that this volume, together with its companions, will for some time to come be the standard work of reference; and all students of aerodynamics will be immensely grateful to the editors and contributors who have collaborated to produce this great work. G. Temple

## Oil in the Middle East

Its Discovery and Development. By Stephen Hemsley Longrigg. Pp. xiii + 305. (London: Oxford University Press, 1954. Issued under the auspices of the Royal Institute of International Affairs.) 25s. net.

THIS is essentially not a technical but a historical survey of Middle East oil. Scarcely anything like it has previously been published, at least for this region of oil-producing territories. The author, executive of one of the chief operating companies, has been connected with the Middle East professionally for nearly forty years (twenty-five as resident); he writes with authority and inside knowledge of men and organizations responsible for developing vast petroleum resources of Persia, Iraq, Levant and Arabia, from small beginnings to their present magnitude.

The background to these chronicles is essentially political and economic: sometimes there is peaceful co-existence between them; occasionally decidedly the opposite is portrayed, for example, in his lucid chapter "The Tragedy of Persia", one of the best objectively written accounts of what nationalization of that country's oil really meant to Britain, and still implies. The whole story of fortunes and misfortunes of Middle East oil is vividly unfolded, from early days in the nineteenth century; before, during and after the First World War; between the Wars; and the Second World War and since. The parts played by all-American and international companies (1946–53) are not the least enlightening and valuable sections of the book.

While it deserves a conspicuous position in all libraries of the oil industry, this book will especially appeal to executives and others who have devoted their lives (and to those who still do) to founding, expanding and administering huge international petroleum undertakings, not only in the Middle East but also in other parts of the world where oilfield developments are on a comparable scale. H. B. Milner

## Birds as Animals

1: A History of Birds. By James Fisher. (Biological Sciences.) Pp. 208. (London: Hutchinson's University Library, 1954.) 8s. 6d. net.

THIS work is based on the author's "Birds as Animals", rewritten and enlarged, and is intended as a general introduction to ornithology for university students. Owing to the small size of the book, it has only been able to give a brief survey of the various aspects of the subject; but nevertheless it is a useful summary of what is known. For those who wish to pursue the subject further, there is a voluminous bibliography at the end of the book.

The first three chapters are devoted to an account of the early bird historians and more important writers, based on Newton's "Dictionary" and Cassey Wood's two volumes, which last mention several authors not available to Newton. Systematics and bird specification are dealt with in separate chapters and might well have been combined, and the same may be said of that devoted to bird history, by which the author means the geological history of birds. It is difficult to treat these subjects separately without a good deal of overlapping. In the chapter on geographical distribution we have interesting accounts of some of the birds met with by early visitors to the Americas; but there is rather a dearth of information in regard to the East Indies and Australia. The long account of Audubon and his works might well have been replaced by more information on the birds discovered by Cook. The number of birds is a subject to which the author has paid much attention, and accordingly he devotes a chapter to tell us what he knows. Finally, there are chapters dealing with cycles, changes in numbers and the effect of man on bird populations. N. B. Kinnear

## An Introduction to Plant Physiology

By Dr. W. O. James. Fifth edition. Pp. viii + 303. (Oxford: Clarendon Press; London: Oxford University Press, 1955.) 17s. 6d. net.

THIS well-known and highly esteemed little book is now brought up to date by the incorporation of new material on respiration, photosynthesis, mineral nutrition, hormones, and other aspects. The insertions have mostly been woven skilfully into the older text, though a contrary instance is the inclusion of two rather different accounts of axillary bud dormancy. The mechanism of nitrogen fixation is not now so unelucidated as the author suggests.

A few minor weaknesses persist from earlier editions; thus two different formulæ are still given for preparing molar sucrose, without explanation (and it is now implied, erroneously, that the osmotic pressure of a weight-molar sucrose solution is 34·5 atmospheres). The unqualified statements that wheat grains have never been found to survive for more than sixteen years and that the *Calluna* mycorrhiza fixes nitrogen could be questioned.

For much the greater part, however, the text has the stamp of authority, and where finances permit the elementary student of botany to acquire textbooks limited in scope to a single branch of the subject, this one can be strongly recommended. A first reading yielded four misprints only. G. Bond

## Elementary Qualitative Analysis on the Small Scale

By Dr. Peter Woodward. Pp. viii + 92. (London: Oxford University Press, 1955.) 12s. 6d. net.

THIS essentially practical manual for sixth-form pupils and university freshmen deals with the analysis of simple mixtures of salts soluble in acids. The first of the text's five parts contains an advocacy of small-scale methods; the second describes the apparatus required and techniques recommended; the fourth deals with the chemistry of the separations and the fifth with the analysis of more difficult mixtures of anions. Although in general the schemes of analysis (Part 3) are on familiar lines, the book is unusual in its content.

Thus the author has omitted the customary long lists of reactions of the ions concerned; his outstanding contribution is the introduction into school practice of some of the new methods and principles which are revolutionizing qualitative analysis. One example must suffice—the passage of hydrogen sulphide under pressure. Dr. Woodward uses, not the elaborate apparatus described in most books but a small flask attached to an ordinary Kipp's apparatus. The reviewer can testify to the efficacy of this procedure and to the pleasure with which pupils adopt it.

With a touch of genius the author has added appendixes describing: the separation of cobalt and nickel by paper chromatography and the removal of phosphate by exchange adsorption, thus affording exercises for the abler pupils and indicating the way analysis is developing. The methods herein described should come as a boon to teachers and should help to promote a happier presentation of analysis.

G. Fowles

# THE PEACEFUL USES OF ATOMIC ENERGY

## THE GENEVA INTERNATIONAL CONFERENCE

By Sir JOHN COCKCROFT, K.C.B., C.B.E., F.R.S.

THE Geneva Conference on the Peaceful Uses of Atomic Energy organized by the United Nations Organization has been a remarkable experience for those fortunate in participating. It was attended by 1,400 delegates and observers from seventy-three countries. More than a thousand papers were prepared for the Conference, of which 450 were read.

The more general topics such as the future requirements for energy and the role of nuclear power were discussed in three days of plenary sessions. This was followed by nine days of technical discussions going on from 9 a.m. to 5.30 p.m. in three parallel sessions for reactor technology, chemical and metallurgical technology and biology and isotopes. Adequate time was allowed for presentation of the papers, which were simultaneously translated into four languages, and discussion periods of ten minutes or so were fully used.

Besides these, innumerable detailed discussions proceeded in the broad corridors of the Palais des Nations, which is conveniently provided with comfortable seats ideal for such a purpose. Advantage was also taken of the unique gathering of distinguished scientists to arrange many informal seminars. Thus a whole-day seminar on field theory was attended by theoretical physicists from the United States, the United Kingdom and the U.S.S.R. and many other countries, and was the first occasion on which Russian and Western physicists have met for discussion of this subject since 1937. Prof. E. O. Lawrence and Prof. V. I. Veksler attended seminars on high-energy accelerators following the evening lectures which they gave on their own accelerator work. The scientific and technical activities were supplemented by innumerable receptions, lunches and dinners, so that every available minute was occupied from 9 a.m. until midnight, and the Conference was a test of physical fitness unparalleled in our experience.

The main weight of the papers in the sessions on reactor technology and chemical and metallurgical technology came from Britain, the U.S.S.R. and the United States, though there were many valuable contributions from other countries. The Conference led to a lifting of the veil over the atomic energy programme of the U.S.S.R. and coincided with the coming into effect of a revised declassification policy of Britain, Canada and the United States, decided in principle nine months ago.

So we heard a large number of valuable papers on research reactors and power reactors and their associated technology. From the nine hundred or so possible types of power reactors in Dr. A. M. Weinberg's classification, about twelve have been selected for construction in experimental or prototype form by five nations. Thus graphite-moderated reactors using gas, water or liquid sodium for cooling are being built by Britain and France, the U.S.S.R. and the United States, respectively.

Water-moderated reactors using solid fuel are being studied in four types using light or heavy water, and in designs in which the water boils and is transmitted direct to a turbine or in which the water circulates through a heat exchanger to raise steam. Homogeneous thermal reactors were described in at least three forms, while experimental fast reactors are being built by both the United States and the United Kingdom.

Prof. D. V. Blokhintsev, who is head of the Institute of the Academy of Sciences of the U.S.S.R. devoted to reactor development, described the first Russian water-cooled graphite-moderated power station, which has been operating for a year and produces 5,000 kilowatts of electricity. The power reactor was designed on severely practical lines with no regard for neutron economy, since uranium fuel containing 5 per cent of uranium-235 enclosed in stainless steel tubes constitutes the fuel element. So fuel costs are very high, and the regeneration of secondary plutonium fuel is low. The reactor has proved to be very reliable in operation and is providing experience from which a 100-megawatt reactor is now being built. This reactor will also use highly enriched fuel and is expected to produce power at a cost of 10–20 kopecks per unit, as compared with an average price for conventional stations of 10 kopecks. Other types of power reactors are being experimented with, including fast reactors ; but the state of development appears to be behind American and British progress.

The American papers on power reactors and nuclear technology show a very broad development in this field. Very detailed papers were presented on the American pressurized water reactor which is to develop more than 60 megawatts, the sodium-graphite reactor developing 75 megawatts, the boiling heavy-water reactor developing 180 megawatts, the homogeneous aqueous and liquid metal-fuelled reactors and the sodium-cooled 62-megawatt (fast) experimental breeder reactor. These papers were supplemented by most interesting models in the exhibition at the Palais des Nations, together with specimens of the fuel elements to be used.

These reactors form part of the American five-year programme of experimental and demonstration power reactors which will be completed by 1960, so that by then the United States will be generating 700 megawatts of electricity from nuclear stations.

Britain presented papers on the engineering details of the Calder Hall graphite-moderated gas-cooled reactor and the Dounreay fast reactor. Models of these reactors were shown in the exhibition, together with a most interesting colour film on the building of the Calder Hall reactor. Britain also contributed many papers on reactor technology. One of the most interesting described the results obtained with the zero-energy fast reactor—ZEPHYR—which showed that in a plutonium-fuelled zero-energy fast reactor, for each plutonium atom destroyed in the core, two new plutonium atoms are produced in the blanket. Fission of the uranium-235 in the blanket plays an mportant part. The full-sized fast reactor will not realise the full theoretical breeding gain, owing to absorption of neutrons by coolant and other materials. Nevertheless, high-gain factors seem assured, and Dr. W. H. Zinn predicts a breeding gain of 60–70 per cent with the American plutonium – uranium-238 experimental breeding reactor, leading to a time to double the fuel investment of five to six years.

The aqueous homogeneous breeding reactor using the thorium – uranium-233 fuel cycle was predicted to have a breeding gain of 10–15 per cent, together with very high outputs per kilogram of fuel and comparatively low capital costs. The uranium-238 – plutonium fuel cycle does not promise breeding in the thermal region. Since thorium has also favourable properties metallurgically, its use in thermal reactors seems likely to be generally important in the second decade.

Our best view of Russian nuclear technology was in the field of nuclear constants. The nuclear data obtained by the U.S.S.R., Britain, the United States and France have all been plotted on a common basis and show very good agreement, showing that Russian techniques and instruments are as highly developed as those in Britain and the United States.

The papers on the economics of nuclear power showed a general consensus of opinion that capital costs of nuclear power stations will be appreciably higher during the next decade than those of conventional power stations. Typical values were £120 per kilowatt for a 150-megawatt gas-cooled graphite reactor; 250 dollars per kilowatt for a 250-megawatt heavy-water reactor; 200 dollars per kilowatt for a 75-megawatt sodium-graphite reactor. The first figure is based on the construction cost of Calder Hall; the last three on design studies only. Fuel costs were predicted to be lower than for conventional stations; but this depends largely on the 'burn-up' of the uranium-235 which is achieved. Prediction of heat extraction per ton of uranium varied from the equivalent of 10,000 tons of coal to more than three times this figure. But little experimental evidence is yet available.

The figure for the overall cost of nuclear power depends a great deal on the interest rate assumed. The Americans use high capital charges—of the order of 12 per cent—and their forecast overall production costs during the next decade lie between 7 and 10 mills, while the great bulk of their power is generated at about 5 mills. In Britain nuclear power is quasi-competitive.

The forecasts of the proportion of electricity to be generated by nuclear power in 1975 varied, from 40 per cent in Britain to an American figure lying between 1 per cent and 15 per cent, depending on whether costs are 9 mills a unit or 6 mills a unit at that time. The Canadian position seems to be rather similar. Forecasts of the usage in other countries by 1975 varied greatly, depending on the amount of hydroelectricity still to be developed and its capital cost and location. Most Western European countries will not require appreciable amounts of nuclear power before 1965.

Dr. H. J. Bhabha's paper on India's energy requirements showed that 80 per cent of the energy comes from the burning of dung. The energy consumption per head is one-tenth of that of Britain, and electricity consumption one-eightieth. This is planned to increase seven-fold by 1975, so electrical capacity will have to increase from $3\frac{1}{4}$ million kilowatts to 25 million kilowatts. The undeveloped hydroelectric capacity of 35 million kilowatts could provide most of this; but there are some areas far from hydroelectric sources where thermal power stations are at present used, and here nuclear energy will play a part. India is especially interested in the use of thorium.

Papers on the power requirements in other 'under-developed countries' showed a need for power reactors developing about 10 megawatts of electricity. These may also find applications in remote mining areas. Power costs in many of these areas are already much higher than normal costs—up to four times higher. Power from small units will necessarily be higher in cost; but papers presented by the United States suggest that a reactor of the boiling-water type could probably produce power at 15 mills, which is almost competitive with commercial 10-megawatt power stations.

It appears, however, that a much more detailed 'market survey' of the power needs and requirements of these countries is required before we can assess the volume of applications in the next two decades.

The position at the end of the century is easier to assess, since the economists and statisticians agreed in predicting a minimum energy requirement of 7 or 8 billion tons of coal-equivalent by the year 2000, of which half would be required for generating electricity. Hydroelectricity is predicted to supply 1 billion tons equivalent, and it is hoped that nuclear energy would by then be able to do the work of 2–3 billion tons of coal a year. The forecast of British requirements for nuclear energy at that time is about a tenth of this figure.

Papers on the occurrence of uranium and thorium suggest that in the 1960's plenty of fuel will be available at a cost of about 10 dollars a lb. Supplies of at least one million tons were reported to be available and, if by the end of the century breeding is achieved, only a few thousand tons of uranium and thorium a year are required to undertake the predicted task of the economist.

The biological sessions discussed the hazards of radiation to workers in the atomic energy industry and to the general public. The excellent work done by the International Commission on Radiological Protection in determining safe levels of radiation and safe amounts of radioactive materials was described, and it was agreed that these recommendations ought to be incorporated into world-wide codes of practice. The World Health Organization undertook to help countries new to atomic energy development. The genetic problems of radiation were also discussed in brief sessions, and there was agreement about the inadequate experimental data and the need for increasing the scale of experimental work. Besides the United States and Great Britain, several other countries will undertake experimental work. The work is, however, expensive, and may easily cost £100,000 per annum if significant results are to be achieved within ten years.

Numerous papers were presented describing the applications of radioactive isotopes to biology, medicine and industry.

An interesting picture of the state of development of Russian pure nuclear physics was revealed by Prof. Veksler's evening lecture on high-energy particle accelerators. The U.S.S.R. now have the highest-energy synchro-cyclotron in the world—producing 660-million volt protons. They have also nearly completed a 10-billion volt proton synchrotron. This accelerator is of a similar design to the

Berkeley 6-billion volt bevatron. It uses 36,000 tons of steel in a magnet having an air gap of 2 m. × 40 cm.; so for the next three or four years the U.S.S.R. will have more powerful machines than the United States. Britain is now far behind both countries in its equipment and work in this most important field of nuclear physics.

In general, we have gained the impression that the U.S.S.R. have an enormous deployment of scientific effort in the field of atomic energy, and that their output of scientists and technologists from their universities is quite adequate to maintain this without starving other activities.

The Conference has been more successful than we had dared to hope from such a large gathering. It has brought together East and West after a long period of separation in the physical sciences. It has been a meeting ground for innumerable friends from all parts of the world. It has enabled us to discuss how best we can help other countries, and has done a great deal to re-establish the normal pattern of communication in the scientific world.

---

# THE CULCHETH LABORATORIES OF THE UNITED KINGDOM ATOMIC ENERGY AUTHORITY INDUSTRIAL GROUP

By DR. A. B. McINTOSH

THE White Paper, "A Programme of Nuclear Power" (Cmd. 9389), has directed attention to the work of the Atomic Energy Authority composed of the Weapons Group (A.W.R.E.), the Research Group (A.E.R.E.) and the Industrial Group. Each is represented by a member of the executive under the chairmanship of Sir Edwin Plowden.

Under Sir Christopher Hinton, its managing director, the Industrial Group is responsible for the design, construction and operation of plants for the production of fissile material and for the prototype nuclear power stations at Calder Hall and Chapel Cross. It is also responsible for advice and guidance to the industrial firms which will undertake the construction of the power stations for the Central Electricity Authority proposed in the White Paper. In collaboration with Harwell, it also pioneers new types of reactors in conformity with the policy laid down in the White Paper.

Within the Industrial Group there are three technical branches: Engineering, Operations, and Research and Development, each under its own director. The design and construction of such projects as the reactors at Calder Hall, Chapel Cross and the large experimental fast reactor at Dounreay are the responsibility of the Engineering Branch. On completion of the plants, the Operations Branch becomes responsible for operation and level of production.

The responsibility of the Research and Development Branch under its director, Mr. L. Rotherham, is: (1) removal of difficulties which may impede the attainment of full production in any part of a production plant and the development of works processes; (2) provision of information to support the design of new plants and prototype reactors; (3) longer-term study of problems which arise from production plants and design studies.

The Branch works in close collaboration with the Research Establishment at Harwell, which undertakes part of the work.

In the Research and Development Branch, the emphasis is always on the technique at a particular date, and all work is planned and progressed in the same way as the engineering construction programmes to which the major part is intimately linked. It is research applied to industrial needs and not pure research, but in all its work there is close co-ordination and collaboration with the Research Group at Harwell. This is especially important in the earliest stages, when the feasibility of future reactor systems is being studied.

There are at present four laboratories in the Research and Development Branch, with a fifth in course of formation for work on the Dounreay site. In each of the laboratories there is a large measure of local autonomy and authority. At the Industrial Group Headquarters at Risley there is a section of the Research and Development Branch working in close collaboration with the design engineers and the headquarters organization of the Operations Branch. Part of the responsibility of this section is that of carrying out theoretical calculations for the four existing laboratories at Capenhurst, Windscale, Springfields and Culcheth.

Except for some specialized fields in which Harwell is responsible, these laboratories, with a scientific and experimental complement of approximately eight hundred, provide a development effort for sanctioned construction projects which are the commitments of the Industrial Group. The Capenhurst Laboratory deals mainly with problems of an engineering nature, such as fluid flow and heat transfer. At Windscale the laboratories are largely devoted to radioactive chemistry, metallurgy and physics, arising from reactor problems at Windscale and Calder and the chemical problems of the plutonium separation process. In Culcheth there is a responsibility for the selection of reactor materials and for work on the extraction of these materials where they may not be commercially available. The small-scale work carried out at Culcheth is then extended to a larger scale at the Springfields Laboratory, which is responsible for the development of fuels and fuel elements.

Culcheth is the only laboratory not on a works site; but it is associated very closely with the Engineering Design Branch at Risley. This gives the laboratories a responsibility for the initiation of work at the feasibility and planning stage of new reactors, especially in the selection of materials for reactor components.

To carry out the commitments of the White Paper, increases in staff in the Research and Development Branch of the Industrial Group are necessary. The Culcheth Laboratories have a present complement of approximately 160 scientific and experimental staff. They are extensively equipped with all the tools required for modern metallurgical research and include laboratories specializing in X-ray diffraction techniques, electron microscopy and ceramics. How-

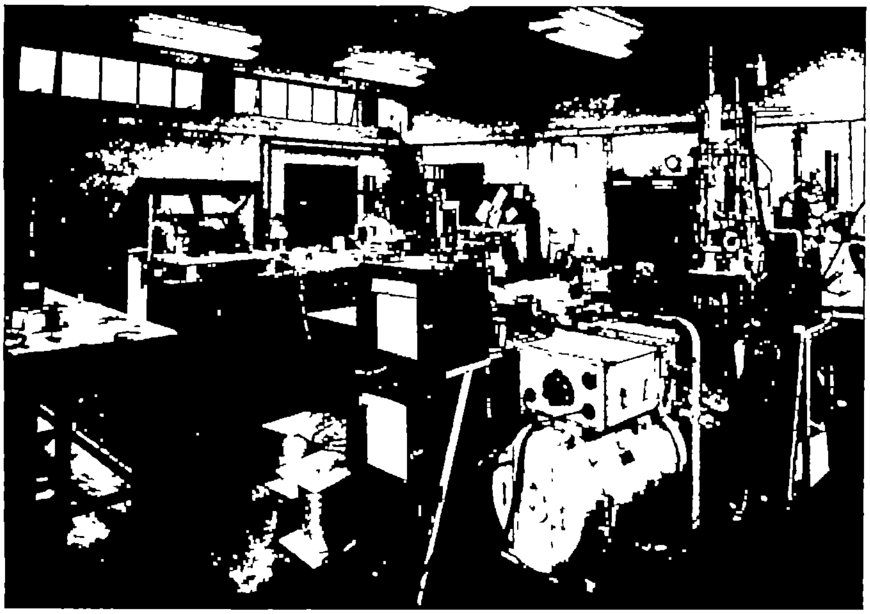

Fig. 1. Metallurgical Laboratory, Culcheth

ever, apart from the large Creep Section and the Materials Inspection Group, both of which have rather special functions, the work of the remainder of the Laboratories is organized to produce results by a planned date for the main programme of engineering construction projects. The objectives of the projects are in all cases the furtherance of the programme of nuclear power development outlined in the White Paper and the development of prototype reactors.

From an overall view, many problems of nuclear power production in the various types of reactor, whether fast fission, thermal or homogeneous, present a common basis. The main questions are of compatibility of materials, the winning of selected metals, the physical metallurgy of chosen alloys and the deformation of metals both in fabrication and under irradiation.

*Fuels.* When uranium is irradiated, it undergoes dimensional changes which, if sufficiently large, impose stresses on the fuel container. Similar changes are produced by thermally cycling the material, particularly if the cycle includes a phase transformation. These changes affect the life of the fuel elements adversely and limit the operating temperature and the rate of operation of the pile. To achieve the enhanced efficiency and lower production costs visualized in the White Paper, work is in hand to limit these two forms of irradiation damage.

Two possible methods of reducing irradiation damage are by alloy additions and by suitable heat treatment. The former necessitates manufacturing techniques which are complicated by the extreme chemical reactivity of uranium. These techniques include vacuum or inert atmosphere arc melting, melting by electron bombardment and powder metallurgy. The latter methods are particularly appropriate for the production of fuels which are permeable to gas, a property which may be desirable. It is worth recording that all melting equipment used at Culcheth was designed and built in the Laboratories and includes two d.c. arc furnaces operated from welding generators. An electron-bombardment furnace of novel design will be operating in the very near future.

Once the alloys have been prepared, physical and mechanical properties such as thermal conductivity, thermal expansion, creep strength and permeability to gas are measured. The behaviour of the material under various thermal cycling treatments is determined. In those cases where the fuel may come into contact with the coolant, suitable corrosion tests assess the compatibility.

*Canning materials.* The economic production of electrical power from nuclear reactions demands the highest efficiency at all stages of operation. These demands are made not only on the reactor fuels, but also in the associated components such as the cans which contain the actual fuel.

In thermal reactors the number of spare neutrons is so small that the paramount requirement for canning materials is that they should have small capture cross-sections for neutrons. If these conditions are to be fulfilled, the most desirable elements for canning include aluminium, beryllium, magnesium and zirconium. These metals do not, however, possess all the other required properties, and work is in progress to assess the improvements which may be achieved by the addition of minor alloying additions to the parent metals.

In fast reactors, the necessity of minimum absorption of neutrons is less important and must be balanced against the need for a metal which can withstand as high a temperature as possible. This focuses attention on the refractory transition metals such as titanium, zirconium, vanadium, niobium, tantalum, molybdenum, tungsten and rhenium. Of these metals, titanium has received considerable attention in recent years as a constructional material, and some of the others have been the subject of research, while most have been used in the form of ferro alloys for additions to steel. At Culcheth, methods have been developed for the extraction of some of these metals in a very pure state, and, for the first time in Britain, vanadium and niobium have been prepared in a ductile form. Techniques have also been devised for the fabrication of these materials, and determinations have been made of their physical and mechanical properties.

It has been found that in some cases a metal or alloy which in other respects possesses highly desirable properties has to be rejected because it reacts with uranium at the appropriate reactor-operating temperature. Methods under investigation to overcome this problem include the deposition of refractory metals from volatile compounds and the use of oxide coatings to separate the fuel from the can.

*Breeder materials.* In order to maintain and improve stocks of fissile material and to take full advantage of the new types of reactor which promise

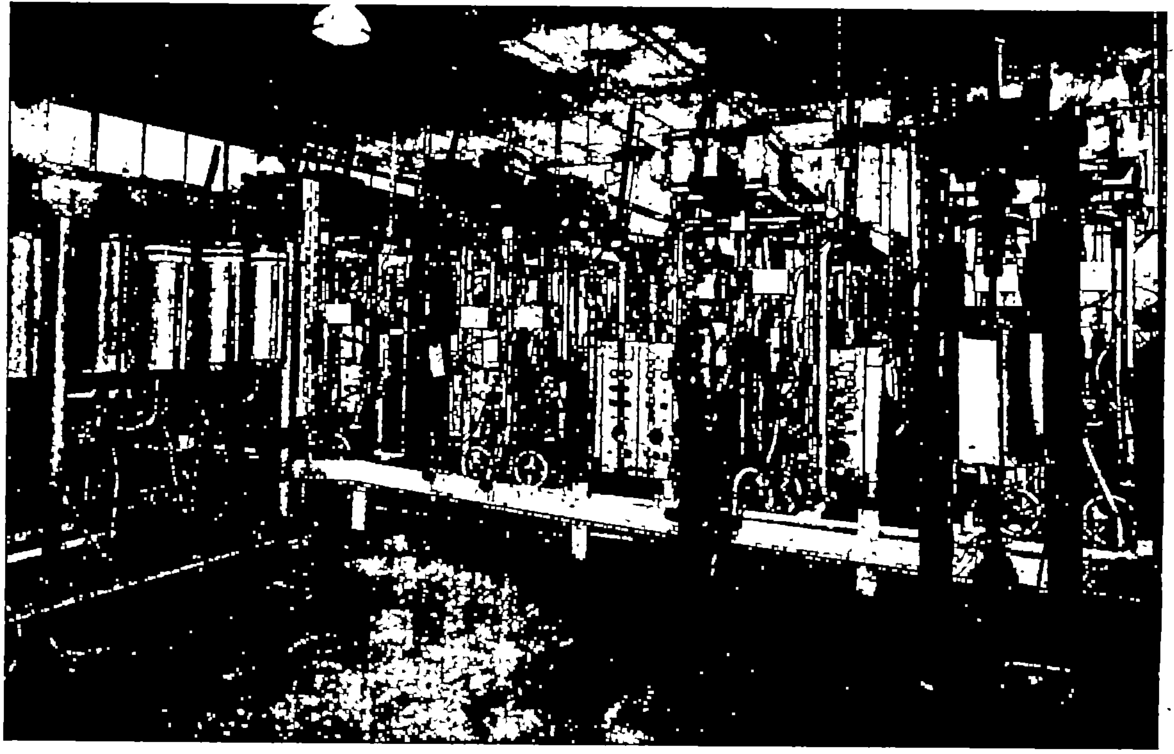

Fig. 2. Creep Laboratory, Culcheth

to be made available as a result of experimental work at Dounreay, it is essential that fresh supplies be obtained by 'breeding' or converting suitable elements. Two such elements are thorium-232 and uranium-238 which, under irradiation, absorb neutrons and then undergo radioactive decay to yield the two fissile materials, uranium-233 and plutonium-239, respectively. The Research and the Industrial Groups have been examining the economic prospects of thorium reactions and, at Culcheth, in view of the success in the preparation of refractory metals by various methods, similar processes are being examined for the extraction of thorium from monazite.

*Coolants.* The coolant is the all-important medium through which the heat developed in the core of the reactor will be removed to generate the required steam pressure in the heat-exchanger. Coolants which may be employed in nuclear reactors include water, gases and liquid metals. Not only must the corrosive behaviour of a coolant be investigated, but also many other of its chemical and physical properties, depending on the particular application. As an example, the Dounreay reactor is likely to employ a liquid-metal coolant in the form of sodium–potassium alloy. For this and other liquid metals considered, precise knowledge of ignition temperatures is essential if an accurate estimate is to be made of any hazard which they may present. This ensures that the safety precautions installed are adequate without being excessive and uneconomical.

*Constructional materials.* The Atomic Energy Authority's products are such that to contain or process them constructional materials must have, in addition to their normal properties, some feature such as resistance to corrosion in conditions where this is more than usually severe, or where loss by pick-up of a valuable process gas must be avoided. Work is constantly in progress at Culcheth on the examination and improvement of plant materials by the development of new alloys or superior manufacturing techniques. This work frequently results in a combination of reduced capital and running costs with an increase in the technical efficiency of a process.

*Materials Inspection Group.* In any large organization, it is essential that routine tests should be made to ensure that all materials employed are of suitable quality. This service to the Inspection Branch is carried out by a section which also acts as a works metallurgical laboratory for some sections of the Industrial Group. Engineering parts which have received particular attention are brass bellows, water-coolers and bearings.

*Creep.* The Culcheth Laboratories possess the only creep-testing facilities in the Atomic Energy Authority, and extensive tests have been carried out in inert atmospheres, on a scale probably larger than any attempted elsewhere in Britain. It is believed that, previously, the usual type of precision mirror extensometer had not been used for routine creep tests of materials requiring protection from atmospheric attack, as an enclosed extensometer requires some device whereby, during the course of the test, the mirrors may be reset without breaking a gas seal. The Laboratories have, however, designed, built and successfully operated enclosed mirror extensometers of this type. Materials tested include specimens of proposed canning metals and of uranium itself. Creep-testing machines have also been used for stress-relaxation tests on specimens of the all-welded steel structure of the pressure shell of the thermal reactor under construction at Calder Hall.

Long-term studies as carried out in the Physical Metallurgy and Creep Laboratories aim at providing the basic information for the development of fuels, canning alloys and materials of construction for advanced types of reactors. Fundamental research in the Creep Laboratories is at present directed towards the hardening properties of solid solutions, based on aluminium–copper alloys. Starting from this simple alloy, additions of elements with different electron configurations and differing atom sizes can be examined. From this it is hoped to deduce the relationship between the size of the atom and the electron structure, the consequent effect upon hardening and ultimately the creep-strength. Results obtained from a simple alloy should be applicable to the development of reactor materials.

In the long chain of development between the concept of a new reactor and its operation, the Laboratories at Culcheth with their specialized interests in chemistry, physical chemistry and deformation of metals provide an important link.

# THE PLANT BREEDING INSTITUTE, CAMBRIDGE

On July 15 the new buildings and experimental grounds of the Plant Breeding Institute, Cambridge, were officially opened by Mr. D. Heathcote Amory, Minister of Agriculture, Fisheries and Food. The guests of the governing body included the Vice-Chancellor of the University of Cambridge, the Mayor of Cambridge, the City Parliamentary member, officials of the City and County and representatives of the Agricultural Research Council, the Ministry of Agriculture, the National Agricultural Advisory Service, research institutes and university departments.

In his opening remarks the chairman of the governing body, Sir Frank Engledow, paid tribute to the classic work on genetics and plant breeding of the late Sir Roland Biffen, the first director, whose early researches not only stimulated the development of genetic science and its application to the improvement of agricultural plants, but also resulted in the foundation of the Institute in 1912 at the University School of Agriculture. Biffen's work was essentially that of a great individualist who was among the first of the few scientists to appreciate the epoch-making significance of Mendel's genetic work. But Biffen's scientific acumen and imagination led him to apply the new knowledge to crop improvement, and he chose wheat on which to experiment and test the validity and value of the new knowledge. This started a new era in plant breeding, and the work at the Institute developed considerably under its two succeeding directors, with the ultimate establishment of the present greatly enlarged research centre.

The Minister, in declaring open the new buildings, said the occasion was significant in marking the fruitful collaboration of agriculture with Cambridge scientists. He welcomed the closer association of scientific research with the task of improving the productivity of British agriculture, and mentioned the great work that had been done in recent years in increasing the output from the farms of Great Britain. He emphasized the great importance that the Government attaches to agricultural research, and stated that although there has been a recent change in the administration of this research through transfer of control to the Agricultural Research Council, this would not mean any lessening of the Government's interest and support; he, himself, would continue to have the closest association with research work through the Privy Council committee dealing with this important matter.

The director of the Institute, Dr. G. D. H. Bell, coupled his thanks to the Minister with acknowledgments to all who had helped in the task of establishing the Institute in its new home, finally separated from the University. He paid especial tribute to Sir Frank Engledow, not only for his important scientific work in the Institute, but also for his valuable help and guidance, together with that of

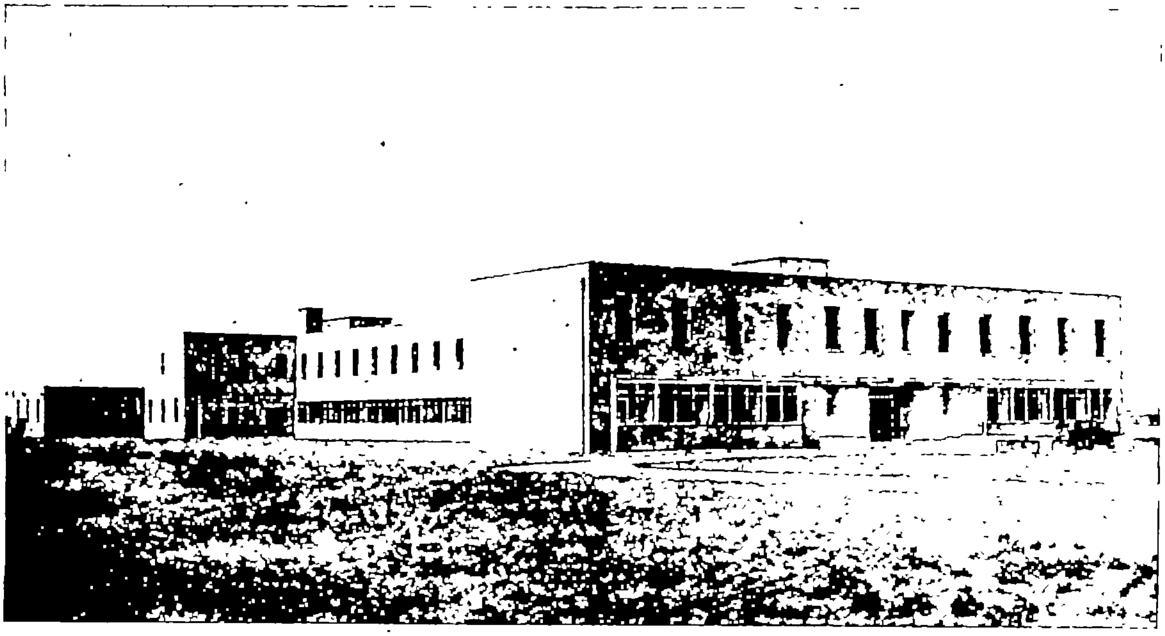

Fig. 1. Plant Breeding Institute, Cambridge, showing the main entrance to the building (right) and the range of laboratories extending from it

members of the governing body. There was much to do, and in developing both fundamental and applied research for the improvement of crops, he saw a satisfying task for his colleagues and himself. There must be the closest integration of science and agriculture, and the facilities which have been provided for the Institute gave the greatest opportunity for those engaged in contributing to scientific knowledge and in breeding improved varieties of crops.

---

The new premises of the Institute are situated on Anstey Hall Farm, Trumpington, some 2¼ miles to the south of Cambridge, and adjacent to the headquarters of the Eastern Province of the National Agricultural Advisory Service. The situation is not only appropriate for a research station that is to devote its attention to the arable crops of the drier parts of England, but it also makes possible the continued close liaison with the School of Agriculture of the University, as well as ensuring easy association with other University departments. Consequently the Institute is able to contribute to the teaching in the University, while it also has the inestimable benefit of close association with the research workers in various University departments.

The Trumpington premises have been planned so that the laboratories, offices, glasshouses and all other facilities are situated on the site being used for growing the plant-breeding material. This centralization is of the greatest value in work of this kind. It has the virtue of every worker having his field-material continually under his day-to-day care, with the consequent efficient organization of time and labour. It is no longer a major expedition to visit material growing in the field, the laboratories do not suffer from isolation from the living material, while there is the easiest transition from field-investigations to laboratory work. The unification, and the ensurance of the integration of field- and laboratory-work, are essential for the proper organization of research work devoted to the study of the behaviour of cultivated plants in the field with special reference to their improvement.

The buildings comprise a main and an ancillary block, the former housing the offices, library, main laboratories and other services, and the latter including the implement sheds, soil sterilizing and potting rooms and glasshouses. The two blocks are served by a concrete road and are separated from one another by part of the experimental plots, being situated a quarter of a mile apart. All parts of the premises are consequently of easy access, and there is a minimum of transport of materials involved.

The main building has interesting features from the point of view of the organization of scientific research work devoted to a wide range of problems in a number of different plant species. In the first place, except for the facilities provided in the ancillary buildings, which are largely concerned with the glasshouse work, the whole of the working requirements are provided under the one roof. The building is of two stories, to comply with local planning requirements, although there is a basement laboratory under a portion of the south wing for housing controlled-climate chambers and refrigeration cabinets. The ground floor is, except for a conference and lecture room, devoted entirely to laboratories, a specially constructed fire-resistant seed store, a threshing room and a sugar-beet tare house: the whole layout having as its main objective the centralization of the main servicing departments in connexion with each crop section. This distribution has made it possible to devote the first floor primarily to private rooms, administrative offices and library, but there are also research laboratories for biochemistry, serology and cytology, and a large cereals room.

Although each crop section is provided with its own laboratory, it has been found necessary to provide in addition service laboratories such as cytology, chemistry, pathology and physiology for use by all sections, as well as the common facilities for controlled-climate growth, frost-hardiness testing, and germination tests. This means that there are essentially two kinds of laboratories—crop sectional and common service—to ensure adequate facilities for the different lines of investigation and the various crops included in the programme of the Institute. These developments are necessary to deal with the scientific techniques that must be incorporated in plant-breeding work involving the improvement of the important economic characters of crop plants.

Plant breeding is a slow process compared with some other branches of research work, and it can be very consuming in labour as well as time. Apart from the use of controlled-climate chambers for special purposes, and to increase the number of generations that can be handled in a given period of time, much can be done to economize in time and effort by the use of glasshouses, which are virtually essential for some aspects of plant breeding. The Institute is accordingly provided with standard heated glasshouses for the various crops, and it is possible thereby to continue certain investigations during the winter months. Special light-alloy glasshouses are being erected for the sugar beet programme, which is concerned particularly with the study of artificial polyploidy and other breeding techniques as well as the possibilities of developing beets resistant or tolerant to virus yellows disease. These glasshouses comprise two separate blocks; one is for studying breeding techniques and consists of four banks of air-conditioned compartments which can be used for controlled pollination and seed production of breeding material; the other block includes an insectary for raising aphids, an inoculation chamber, a fumigation chamber, and growing-on houses, the whole being designed to allow work on breeding for tolerance or resistance to virus yellows to continue throughout the year. Extra artificial illumination is provided for winter work, while the houses can be cooled in summer by blinds and water irrigation on the roofs.

The existing facilities provided at the Institute by these buildings and extra land are commensurate with the new responsibilities of the greatly expanded programme of research being undertaken. There is provision for expansion of the staff and of the work to cater for the requirements of plant breeding research on all the important arable crops of Britain.

---

# OBITUARIES

## Prof. R. W. Wood, For.Mem.R.S.

With the death on August 11 of Prof. R. W. Wood at the age of eighty-seven, science has lost one of the last links with the great experimental physicists of the past century. Though his principal contributions to science lay in the field of physical optics, Wood was a man of extraordinary versatility. An artist of no mean ability, a musician and, above all, a teller of stories (not all suited to Victorian drawing-rooms), he had a keen sense of humour and an impish wit which made him the best of companions. Wood's "Physical Optics", now in its third edition, and his little satirical book of poems, illustrated by himself, "How to Tell the Birds from the Flowers", have both been best-sellers for many years.

Wood was a great traveller. Sabbatical years seemed to recur at very close intervals, and Wood's visits to Europe became almost an event in the scientific world. He never failed to bring with him something original and ingenious; and, of course, a fund of new stories. Like his great friend, C. V. Boys, Wood was essentially an experimenter who loved to do everything for himself. A craftsman in the laboratory arts and a manipulator of the very highest dexterity, Wood found it difficult to entrust any substantial part of his experimental work to others. When he embarked on an experiment, everything was sacrificed to its consummation in the shortest possible time. All apparatus and equipment, regardless of its normal purpose, was ruthlessly sacrificed to the end in view; and it only took some fifteen seconds to smash a perfectly good electric light bulb and extract the leadglass stem if Wood happened to be in a hurry for a bit of sealing-in glass.

Wood was born in Concord, Mass., in 1868, and was educated at Harvard and the University of Berlin. He became professor of experimental physics at Johns Hopkins University in 1901, where he took charge of Rowland's machines for ruling diffraction gratings and initiated the production of blazed echelette gratings for use in the infra-red. His published papers, which exceed 250 in number, cover a wide field and include experimental work in physical optics, on interference and diffraction and a study of the groove form and intensity distribution in gratings. He made extensive observations of the optical properties of the vapour of sodium at low pressure in which he observed the fluorescence and resonance spectra. Similar observations were made with the vapour of iodine. He studied the use of infra-red and ultra-violet photography of terrestrial objects and also their application to a study of the moon. These are only a few examples, chosen almost at random, of the many fields in physical optics in which he worked with such distinction. He was one of the really great experimenters with an almost uncanny flair for choosing the simplest and best method of attack. He seemed always to know what would work.

Wood received many honours, including Rumford Medals given by the American Academy of Arts and Sciences and the Royal Society, the Ives Medal and the Draper Medal of the U.S. National Academy of Science for his contributions to astrophysics. He was a foreign member of the Royal Society and was awarded honorary degrees by many of the leading universities of Europe. In 1892 he married Gertrude Ames, of San Francisco.

T. R. MERTON

---

## Lord Horder, G.C.V.O.

IN his long life of eighty-four years, which came to an end on August 13, Lord Horder witnessed and participated in a revolutionary change in the science of medicine and in the organization of its service to the public. In any age he would have been successful, for he was endowed with that indefinable gift for recognition of disease, great skill in clinical examination and sympathy with human suffering which characterize the ideal physician. To these talents he added scientific knowledge and experience. Up to the present century the diagnostician's tools were limited to a few simple instruments to assist the otherwise unaided senses in the examination of the heart, lungs, eyes and larynx. Horder, trained as a pathologist, was able to add to the examination of the patient's body the examination of the patient's blood, his cerebrospinal fluid, his secretions and excretions. He was one of the first to bring the laboratory to the bedside, to foster and promote clinical pathology. It is little wonder that he soon became the most sought-after physician of his time.

Horder's early research work is recorded in contributions to the annual reports of the Medical Officer of the Local Government Board. In the report for 1906–7, he published a paper "On a Study of the Micro-organisms associated with Rheumatic Fever and Malignant Endocarditis". In the report for 1907–8 he contributed a paper with F. W. Andrewes "On the Behaviour of the Leucocytes in Relation to Infection by and Vaccination against the Pyogenic Cocci", and with M. H. Gordon reported "On an Investigation of Protective Agents in Meningococcus Infections". His chief contribution to clinical medicine was a paper on 150 cases of infective endocarditis in the *Quarterly Journal of Medicine* of April 1909, in which he stated that with care a positive blood-culture of one or other of three types of streptococci could be obtained in 90 per cent of cases. In 1907 he edited Abel's "Laboratory Handbook of Bacteriology"; he wrote on pleurisy in Allbutt and Rolleston's "System of Medicine" in 1909; and in 1910 he published his "Clinical Pathology in General Practice", in which he included an account of vaccine therapy. He edited the second edition of the "British Encyclopædia of Medical Practice", published in 1950, and in 1953 published "Fifty Years of Medicine", an expanded version of his Harben Lectures delivered at the Royal Institute of Public Health and Hygiene in December 1952, which are partly autobiographical.

Horder served on the Minister of Health's Advisory Committee during 1935–39, and during the Second World War rendered conspicuous service as chairman of a committee appointed to inquire into the health conditions of air-raid shelters, and also as medical adviser to Lord Woolton at the Ministry of Food.

He promoted many good causes. For example, physical medicine, industrial hygiene, eugenics, cremation and noise and smoke abatement owe much to his advocacy. In particular, the combating of two scourges of mankind, rheumatism and cancer, concerned him. He was chairman of the Empire Rheumatism Council from its inception in 1936 until 1953. As chairman of the Scientific Advisory Committee of the British Empire Cancer Campaign he rendered great service, and he largely instituted a clinical review and follow-up of all cancer cases in London hospitals. Only last year he attended an international cancer conference at São Paulo, Brazil.

"Those whom the gods love die young." Lord Horder gave a new interpretation of the aphorism, for up to the day of his death his mental powers were unabated, and he was still young in spirit, in enthusiasm, and in love for mankind and for the profession which he adorned.

ARTHUR MACNALTY

# NEWS and VIEWS

### New President of the British Association: Sir Raymond Priestley

At the meeting of the General Committee of the British Association for the Advancement of Science held in Bristol on August 31, Sir Raymond Priestley was elected president of the Association in succession to Sir Robert Robinson. An appreciation of the scientific and educational work of Sir Raymond was published in *Nature* (169, 778; 1952) on the occasion of his resignation from the vice-chancellorship of the University of Birmingham.

### Geology at the Imperial College, London: Prof. H. H. Read, F.R.S.

Prof. H. H. Read retires this year from the chair of geology in the Imperial College of Science and Technology, London, which he has occupied with signal distinction since 1939. After active service in the First World War, he returned to the Geological Survey of Great Britain to spend more than a decade in mapping the complex metamorphic and granitic rocks of the Highlands of Scotland and the Shetland Islands. From this wealth of field experience he drew inspiration for his much-quoted advocacy of the contaminated origin of norites, and for a series of classic contributions to geological literature entitled "Meditations on Granite" and "Commentaries on Plutonism". These and other philosophical writings have won him an international reputation as a leading exponent of metamorphic processes and metasomatic granitization, and election as foreign member of numerous geological societies throughout the world. For nearly twenty-five years he has been an enthusiastic and stimulating teacher, first at the University of Liverpool and later at the Imperial College, where he has built up a large and flourishing research school of geology. He was elected a Fellow of the Royal Society in 1939, and besides serving as president of the Geological Societies of Edinburgh, Liverpool and London and of the Geologists' Association, he was universally acclaimed as president of the International Geological Congress held in London in 1948. Four years later, the Geological Society of London awarded him its premier honour, the Wollaston Medal. Not content to rest on his laurels, Prof. Read is still actively engaged in studying the interplay between tectonics, metamorphism and plutonic phenomena in the Grampian Highlands, and in closely directing a team of research workers in a comprehensive investigation of the metamorphic, migmatitic and granitic rocks of Donegal in a concerted effort to illuminate the vexed problem of the origin of granites. Although he now relinquishes the chair of geology and the pro-rectorship of the Imperial College, it is gratifying to record that, as Senior Research Fellow, he will retain intimate ties with the department that thrived so much under his beneficent and invigorating guidance.

### Oil Technology at the Imperial College, London: Prof. V. C. Illing, F.R.S.

Prof. V. C. Illing, professor of geology (oil technology) in the Imperial College of Science and Technology, London, retires at the end of the 1954–55 session. Prof. Illing is a graduate of Sidney Sussex College, Cambridge, and in 1913 went to the Imperial College to carry out research on the fauna of the Stockingford shales of the Cambrian. Early in 1914 he joined the staff of the Geology Department, and became associated with the newly formed Oil Technology Department, being appointed its first professor in 1936. In 1915 he first visited Trinidad, and so began a long association with oilfield operations in the Caribbean area. 1916 found him supervising work being carried out for the Aeronautical Inspection Department in a new laboratory in the Royal School of Mines. In 1944 he was awarded the Murchison Medal of the Geological Society, and in 1945 was elected a Fellow of the Royal Society. Prof. Illing is widely known for his research work and publications on oil migration and accumulation, and for the emphasis he has placed on the study of stratigraphy and geological history in assessing the oil possibilities of an area. He has also stressed the importance of selecting appropriate techniques in the search for oil fields. For many years he has been recognized as an authority on oil developments in Trinidad and Venezuela. His advice has also been sought on oil-field operations in many other parts of the world, and in 1947 he negotiated, on behalf of British and Dutch interests, a settlement with the Mexican Government in connexion with the expropriated oil-fields.

### Department of Scientific and Industrial Research: Mr. E. Barnard, C.B., C.B.E.

Mr. E. Barnard has recently retired from the post of deputy secretary in the Department of Scientific and Industrial Research. Mr. Barnard, who is sixty-three, had a distinguished career in the Gloucestershire Regiment during the First World War, being awarded the D.S.O., and then in 1919 he joined the Department of Scientific and Industrial Research as an assistant principal. In 1928 he was appointed assistant director of food investigation under Sir William Hardy, the then director, and in 1934 succeeded Sir William. He was director of food investigation until 1943, when he returned to the headquarters office of the Department as principal assistant secretary and deputy to the then head of the Department, Sir Edward Appleton. In 1945 the post of deputy secretary in the Department was created and Mr. Barnard appointed to it. He was made a C.B.E. in 1943 and C.B. in 1951.

### National Coal Board Committee for Research into Human Problems

The National Coal Board has set up a Committee for Research into Human Problems, with the following terms of reference: "To consider and approve, in the form of programmes and budgets, the general lines of the Board's research on human problems, having special regard to the needs of Industrial Relations, Medical and Staff Departments; to receive progress reports and to ensure that work on all the items in the approved programmes is properly and promptly carried out; and that the results of research are adequately disseminated". Research into human problems will be carried out by the research branches of the Departments mentioned (and by outside bodies as well) and the Committee's function will be to supervise, with executive authority, the work of the various research branches. The Committee comprises Mr. J. Bowman (deputy chairman of the Board, in the chair), Sir Andrew Bryan (staff member), Mr. W. H. Sales (industrial relations member), Mr. A. H. A. Wynn (scientific member), Dr. W. Reid (production member) and

Mr. J. Latham (finance member). To provide the means of maintaining contact between all people engaged on this research and formal facilities for the exchange of ideas, an Advisory Committee will be set up, and its terms of reference will include the discussion of progress in research in the medical, human and management fields, the suggestion of the lines on which new research projects might be fruitfully developed, and consideration of the ways in which the information gathered and the research findings might most profitably be disseminated and used.

## British Agricultural Delegation to visit the U.S.S.R.

At the invitation of the Government of the U.S.S.R. a British agricultural delegation is to visit that country; this invitation follows the recent visits to the United Kingdom of two agricultural delegations from the U.S.S.R. The United Kingdom delegation will be led by Mr. G. R. H. Nugent, Joint Parliamentary Secretary to the Ministry of Agriculture, Fisheries and Food. The delegation will leave for the U.S.S.R. on September 25 and will return on October 9; its programme will include visits to the Agricultural Exhibition in Moscow, to farms and to agricultural research and experimental stations. In addition to Mr. Nugent, the delegation will include: Prof. H. G. Sanders, chief scientific adviser (agriculture) to the Ministry of Agriculture, Fisheries and Food; Dr. E. E. Cheesman, scientific adviser, Agricultural Research Council; Dr. H. P. Donald, director of the Agricultural Research Council's Animal Breeding Research Organization, Edinburgh; Sir Peter Greenwell, member of the Council of the Royal Agricultural Society of England; Prof. D. S. Hendrie, principal of the West of Scotland Agricultural College; Dr. P. S. Hudson, director of Commonwealth Bureau of Plant Breeding and Genetics, Cambridge; J. Mackie, chairman of the Scottish Committee of the National Institute of Agricultural Engineering; Dr. A. Muir, head of Soil Survey of England and Wales and head of the Pedology Department, Rothamsted Experimental Station; Dr. J. A. B. Smith, director of the Hannah Dairy Research Institute; Dr. A. W. Stableforth, director of Veterinary Laboratories, Ministry of Agriculture, Fisheries and Food; W. C. Tame, under-secretary, Ministry of Agriculture, Fisheries and Food; and representatives of trade unions associated with agriculture. The *News Chronicle*, which was host for one of the recent Russian delegations to Great Britain during part of its stay, has also been invited by the U.S.S.R. to send six representatives; this group will travel with the official delegation, but will probably follow a separate programme.

## The Cleanliness of the British Scene

As the result of a summer of outstanding brightness and delight, in which many in Britain have been prompted to spend the maximum practicable amount of time in the open air, the matter of dreary and blackened buildings, rendered more dismal by the onset of rain, may have been well forgotten for the time. The hour is fast approaching when the issues to be put before Parliament in the Clean Air Bill will arouse the Press, and the attention of the public will be directed to its hoped-for progress through the House. The summer issue, therefore, of a journal that has grown attractive from the efforts of those who have been zealous in the development of smoke abatement is of particular interest at the present time; it is *Smokeless Air* (25, No. 94), the official organ of the Smoke Abatement Society. With the smoke and air pollution that has been the result of the growth of industrial activity in the British Isles, there now looms before us the problem of radioactive pollution associated with the development of atomic energy so necessary to assist our survival as an industrial community. There is a timely reprint in this journal of an address by Sir John Cockcroft, given to the Parliamentary and Scientific Committee on the subject of radioactive pollution (see *Nature*, May 21, p. 873), which is for the time being reassuring. It yet defines a problem which has been very prominent in the news in recent months.

The same issue of *Smokeless Air* also contains a racy contribution from the pen of a Frenchman, Roger Valvert, entitled "A Frenchman looks at Britain's Smoke". A succession of pert reflexions on the Englishman's robustness and toughness in enduring his apparently barbaric forms of heating almost commends the scepticism with which the Beaver Committee report on "Air Pollution" was received last year. We read of "smog, that cocktail of smoke and fog, typical of London and other great industrial centres". Again, "Coal is scarce. One must not waste it. If then this method of heating does not heat, it teaches the English to live in what Continentals would consider cold". Another pleasant gibe runs, "The Englishman to our mind is badly fed and heated, but he has his own flat, or more often house, redecorated every two years, and a well-kept garden. He has a bathroom even if it is arctic. To teach him efficient heating is, therefore, to risk a catastrophe". The author fires his parting shot by suggesting that it would not be a bad thing to observe how the truly sporting spirit helps, that typical characteristic of the Englishman. We shall see when the battle is joined in the coming months. The editor of *Smokeless Air* deftly puts in a final *riposte* by observing that, according to a municipal councillor, the air of Paris will soon be as poisonous as that of London, and he quotes chapter and verse.

## Colour in Foods

The Quartermaster Food and Container Institute in Chicago is an active centre for both fundamental and applied research in food technology. It is responsible for the specifications for foodstuffs supplied to the United States Army, and it maintains close relations with scientific workers in the universities, in industry and in other government departments. This co-operation is fostered through an Advisory Board established by the National Research Council and through various advisory committees, and during recent years a number of specialized conferences have been arranged jointly by the Institute and the Council. Several valuable reports of these meetings have already been published, the latest of these being on "Color in Foods", based on a symposium held in Chicago during November 3–4, 1953 (pp. 186; from the Quartermaster Food and Container Institute, 1819 West Pershing Road, Chicago 9, Ill.; 1954; n.p.). The sixteen contributors discuss a wide range of problems, including the fundamental concepts of colour measurement, the psychological approach to colour preferences, and the nature and reactions of the carotenoids and other food pigments. Several of the papers are concerned directly or indirectly with instrumentation, and they reveal the progress that has been made during recent years in the design of equipment both for research and for routine tests on fruits and vegetables and their products. As a whole, much is included that is of interest to those who are concerned with quality control in food production; the symposium fully discussed the difficulties in correlating colour and quality—in particular, the necessity for considering separately each commodity in terms of its natural colour and of the changes during storage and processing, and also in terms of what is regarded as acceptable and desirable by the consumer. In this connexion, the symposium brings out not only differences in individual and community preferences, but also the effects of external factors such as modern restaurant lighting.

### Archæological and Geological Investigations in South Australia

AUSTRALIAN investigators continue to advance our knowledge of the prehistory of their regions. Long ago it was suggested that little further progress could be made until sites yielding a definite stratigraphy of industries had been discovered and a correlation of cultures with the geological record determined; and further, that in this connexion the fauna associated with the various culture groups must be listed. The problems there are not at all easy to resolve. Prehistory continued until a recent date, and neither the later geology nor the palæontology has been as systematically studied as in Western Europe. A recent number of the *Records of the South Australian Museum* (11, No. 3; 1955) is a useful addition to our knowledge. It contains a long article on the late Tertiary marsupials of South Australia and continues with a study of certain archæological sites at Lake Menindee, a locality near the River Darling in western New South Wales. The Lake is almost always dry except in exceptionally wet periods, such as that, for example, of 1950. In the dune-like area near the northern end of the Lake a stratigraphical sequence of several cultures has been determined, namely, the Tartangan (at the base) and then the Pirrian, with the Mudukian on top. The remains of a fauna and some human bones have been recovered. The industries are made from material foreign to the district, and it would appear that we are dealing with hunting peoples who from time to time occupied the sites either when it was damp or during times of exceptionally heavy rainfall when the Lake had water in it. It would seem clear that at Menindee man was contemporary with extinct marsupials which he hunted for food, and that the dingo only arrived in New South Wales after the time of the first settlement. The age of the earliest levels could be the close of the Pleistocene or the very beginning of the Holocene. The account is well set out; but the illustrations are not adequate in the case of the stone implements. The drawing of stone tools is a specialized art, and more attention could well have been paid to it.

### Scientific Research in India

IN his Thomas Holland Memorial Lecture, given before the Royal Society of Arts on May 19, Sir Alfred Egerton spoke on "Scientific Research in India". After emphasizing that the fruitfulness of science is first and foremost not a matter of money but of outstanding men or women, Sir Alfred said that although much was started before India attained independence, including the Board of Scientific and Industrial Research and, later, the Council of Scientific and Industrial Research to administer the Industrial Research Fund, scientific research only obtained full recognition and encouragement after 1947. This Lecture was essentially an account of the national research laboratories and institutes of India, the work of which was reviewed by a committee with Sir Alfred Egerton as chairman. Sir Alfred thought that the creation of this chain of laboratories in so short a time and the organization it has involved are fine achievements which provide young Indian scientists with the means to show their mettle. He has faith in India's young scientists and technologists and believes that, with initiative and integrity, patience and persistence, they will do work in these institutes which will make them a worthy memorial to India's great public servant, the late Sir Shanti Bhatnagar.

### Scientific Research at South African Universities

A THIRD volume of the "Register of Current Scientific Research at South African Universities" has now been issued, covering research carried out in 1954 (pp. 262. Pretoria: Library and Information Division, Council for Scientific and Industrial Research, 1954). The entries are arranged alphabetically by university departments under their English names; but subject and description are given in the language in which the information was received: in future, it is proposed to supply an English translation of the subject where that is submitted in Afrikaans. There is no index; but a list of contents and a few cross-references afford reasonable safeguards against any particular research being overlooked, and even a comprehensive index could scarcely eliminate the need for a careful examination of the entries in any broad field.

### Plant List of North-West Europe

UNDER the editorship of the Lund Botanical Society, comprehensive lists are being prepared of the plants of north-west Europe, including those of Sweden, Norway, Denmark, East Fennoscandia, Iceland and the Faeroes. In these lists, all species are given point values indicating their rareness within the area of the list, and their occurrence in the different countries is indicated by 'country signs'. Introduced species of diverse kinds are distinguished from the native ones by different types. The main list is completed by lists of synonyms (those most widely used are also given in the main list), of plants protected by law and registers. The present volume on vascular plants has been prepared by Nils Hylander (15 Swedish kroner). A similar list of mosses, algae and lichens (by H. Weimarck, T. Levring and H. Magnusson, respectively) was issued in 1936–37.

### Audio-Frequency Power Measurements

THE eighth in the series of "Notes on Applied Science" prepared by the National Physical Laboratory, Teddington, is a brief pamphlet dealing with "Audio-Frequency Power Measurements" (pp. 16. London: H.M.S.O., 1954; 1s. net). The concept of electrical power and its measurement is introduced by a theoretical consideration of a simple two-terminal load carrying a d.c. current and having negligible leakage between it and its surroundings; and the basic principles of power measurements in an a.c. system free of coupling are outlined before describing in detail the theory of operation of the three modern types of wattmeter. It is stated that on theoretical grounds the electrodynamic type of instrument is the least suitable for the higher audio-frequencies. It is generally superior, however, to the electrostatic or thermal types for speed of response, constancy of calibration, temperature coefficient and other qualities, so that considerable effort has been made by designers to overcome its limitations at the higher frequencies, and the useful frequency-range may yet be extended above 10 kc./s. to 20 kc./s. Many useful practical details of the design and use of the instruments are interspersed with the theory, and the advantages and accuracy of the various types are indicated. Electrostatic and electromagnetic coupling effects are discussed briefly in one section, and the pamphlet concludes with a few remarks about three-phase power measurements.

### *Science Progress*

THE latest number of *Science Progress* (43 ; July 1955) is once more a combination of interesting articles on various aspects of science, shorter descriptions of recent advances in astronomy, physics, meteorology, organic chemistry, geology and botany, some notes on researches and items of interest to scientific workers and the usual comprehensive and valuable list of book reviews. The articles include one on animal communication and the origin of human language by Prof. J. B. S. Haldane, statistical physics and its problems by Prof. C. Domb, aromatic halogenation by Prof. P. W. Robertson, and one by Dr. A. G. Lowndes on the use of the Wolf Rock phonolite as a means of tracing deepwater drift in the English Channel.

### Recent Earthquakes

DURING May–July the greatest earthquake (magnitude 7½) occurred on May 30 in the Volcano Islands (lat. 24¼° N., long. 142¼° E.), and seven other earthquakes caused damage. The most extensive damage was on July 20 at Cotacachi in Northern Ecuador; on July 16 moderate damage was done in the Ægean on Samos and at Soke in Turkey, where about five hundred houses were totally or partially wrecked, four people killed and twenty others injured. Minor damage was done on May 7 in California, May 11 in Ecuador, May 21 in Samoa, May 22 in Austria, and June 5 in Algeria. In Europe, earthquakes were felt in Switzerland (May 2 and 22, and June 16, 17 and 26), Germany (May 12, June 26 and July 2), France (May 12), Norway (June 3) and Spain (June 4). The epicentre of the German earth tremors was in the Onstmettingen–Pfeffingen–Tailfingen triangle, and they were felt with scale 5 (Modified Mercalli) on June 26 and scale 4 on July 2. The epicentre of the Norwegian earth tremor on June 3 was near Sognefjord. Aftershocks of the Orleansville (Algeria) earthquake have continued, and strong earthquakes have been numerous in the Aleutian Islands. On June 28 an earthquake occurred in the north polar region (lat. 86¼° N., long. 70° E.) with magnitude 6. The greatest depth of focus during the three months was 700 km. for an earthquake on May 11 with epicentre at lat. 7° S., long. 123¼° E., in the Banda Sea; and an earthquake with depth of focus 650 km. occurred on June 11 with epicentre at lat. 16¼° S., long. 179° W., near the Fiji Islands.

### Courses in Radiological Physics and Health Physics at the University of Chicago

THE University of Chicago has approved of two new courses leading to the M.S. degree in radiological physics or in health physics, both degrees being awarded by the Department of Radiology. The courses are full-time and last two years, the second of which is spent half on academic work and half in service in the Department at a nominal rate of pay. The work includes physiology, biochemistry, biophysics, anatomy, toxicology and radiological physics. Before they can be accepted, students must have completed the equivalent of the University of Chicago B.S. degree in physics. The courses will commence this autumn. Further information can be obtained from Prof. Lester S. Skaggs, Department of Radiology, University of Chicago, 950 East 59th Street, Chicago 37, Ill.

### Biological Aspects of the Transmission of Disease

A SYMPOSIUM is being arranged by the Institute of Biology on "Biological Aspects of the Transmission of Disease", to be held at the London School of Hygiene and Tropical Medicine during September 29–October 1. Speakers will be drawn from all fields of biology concerned with disease transmission—bacteriology, virology, parasitology and plant pathology. The papers are being arranged in sessions, not by the organism transmitted, but by the method of transmission, that is, passive, direct, or indirect. In order that there can be a useful discussion, preprints will be available before the meeting for those intending to be present. Programmes for the symposium are available from the Institute of Biology, Tavistock House South, Tavistock Square, London, W.C.1.

### Announcements

THE British Society of Rheology is holding a symposium on "Surface Rheology" at the Washington Singer Laboratories, University College, Exeter, during September 22–24. In the evening of September 23 the Society will hold its annual general meeting. Further information can be obtained from the honorary secretary, Dr. P. Feltham, The University, Leeds 2.

THE Industrial Section of the Royal Microscopical Society is organizing a symposium and exhibition under the title "Fibre Microscopy", to be held on November 16 at the rooms of the British Pharmaceutical Society, Bloomsbury Square, London, W.C.1. The papers and exhibits will include work with both the optical and electron microscope, and will be concerned with a large variety of fibres. Further information can be obtained from the Society at Tavistock House South, Tavistock Square, London, W.C.1.

THE eleventh British Commonwealth and Empire Lecture of the Royal Aeronautical Society will be given by Dr. J. J. Green at 6 p.m. on October 6 at the Royal Institution, 21 Albemarle Street, London, W.1. Dr. Green, who is the representative on the Canadian Joint Staff in Washington of the Canadian Defence Board, will speak on "The Growth of Aeronautical Research in Canada during the Post-War Decade". He was the first president of the Canadian Aeronautical Institute, founded in 1954. Further information can be obtained from the Secretary of the Society at 4 Hamilton Place, London, W.1.

WE regret that the obituary notice of Prof. G. F. Shirras in *Nature* of August 27, p. 376, was unsigned; it was written by Dr. John Murray, formerly principal of University College, Exeter.

# THE WORLD HEALTH ORGANIZATION

VIEWED against the background of its basic functions and long-term objectives, the progress made by the World Health Organization in 1954 should be measured less by any particular achievement than by the development of a general attitude which, as a result of six years experience, most of its members seem to be taking towards it (Official Records of the World Health Organization, No. 59).

In all parts of the world there has been a better understanding of the real purposes pursued by the Organization. This evolution is clearly reflected by the nature of the assistance the World Health Organization is asked to provide: there is a definite trend away from requests for supplies and equipment towards requests for technical advice on virtually all aspects of public health. Authorities in many countries now realize that, to be truly effective, the resources of the World Health Organization should be utilized not so much for the temporary alleviation of their problems as for the strengthening of the permanent foundations of their health services.

The most encouraging aspect of the requests received by the Organization in 1954 is the desire shown by many countries to obtain help in working out long-term plans for the progressive and orderly development of their public health services. The growing attachment of Member States of the United Nations to the idea of international co-operation is demonstrated by the great number of inter-country and inter-regional projects. It is also reflected in the continued interest shown by countries in the Organization's efforts to co-ordinate on a regional basis activities carried out on a national level. These methods are being effectively applied in all areas and in practically all aspects of the Organization's work; during 1954, they were used in projects for the development of training facilities, for the exchange of scientific information, and also for the control of communicable diseases and their vectors.

A few examples will indicate the very important part such regional projects played in the total programme of the World Health Organization during 1954.

In the field of education, the Inter-American Centre of Biostatistics in Chile is making a valuable contribution to the improvement of vital and health statistics of all Latin American countries by training technical personnel for the various statistical services. The creation at Alexandria of a regional college of nursing is expected to go a long way towards raising the standards of nursing and nursing education in the countries of the eastern Mediterranean. Countries in Europe took advantage of the advanced training course for waterworks engineers, held in Belgium and the Netherlands, which was attended by engineers from eleven countries.

To exchange scientific information, an important seminar was organized in Wellington (New Zealand), at which thirty-seven participants, from twenty-one countries of the western Pacific, south-east Asia and eastern Mediterranean regions, discussed problems relating to dental health. The conference on African onchocerciasis, convened at Leopoldville and attended by some thirty experts from three regions, yielded valuable information for national and regional campaigns which are to be undertaken in Africa against that disease. The sanitary engineering seminar held in Venezuela proved most effective in promoting inter-American co-operation in the field of sanitation and in integrating public-health engineering activities into the general health programmes of the countries concerned.

An outstanding example of the role being taken by the Organization in the regional co-ordination of national campaigns against specific diseases is the combined effort to be made towards the eradication of malaria from the Americas as a whole. This campaign is to be based on the malaria-control work already being done by individual countries in that region, and on two inter-country programmes assisted by the Organization, one for the Caribbeans and one for Central America.

The second Asian malaria conference, attended by representatives from fifteen countries of south-east Asia and the western Pacific, which took place in the Philippines in November 1954, can be considered as a preliminary step in organizing an inter-regional campaign against this disease. The contacts arranged by the Regional Office for South-East Asia between health authorities of Thailand and of Indonesia are undoubtedly of help to the two countries in their great efforts to bring yaws under control.

There are many examples in the 1954 report of the part the Organization is playing in promoting and especially in co-ordinating essential research work going on in various countries. There is the testing of sorption of non-volatile insecticides by certain types of mud wall, carried out by seven institutes in the Americas, Asia and Europe, and co-ordinated by the Organization. There is also the programme started by the Organization to ensure collaboration among leading experts responsible for field epidemiology studies of trachoma and associated conjunctivitises in different areas of the world. A meeting organized by the Organization in Teheran brought together specialists from Iraq, Syria, Turkey and Iran for a useful exchange of information on the epidemiology of sylvatic plague. Arrangements were also initiated for the exchange of scientific workers between the Nutrition Research Unit in Kampala, the national laboratories of the Indian Council of Medical Research, and the Institute of Nutrition of Central America and Panama.

The overwhelming importance of environmental sanitation for the health programme of the great majority of Member States is emphasized in the report.

In addition to the advisory services in this field given during 1954 to a number of countries, preliminary studies were begun with the view of developing international standards for the quality of drinking-water on the basis of information received from about seventy countries. At the same time, the preparation of material relating to rural water supplies and excreta disposal continued, and it is hoped that this material will contribute to the improvement of sanitary conditions in the rural areas where more than three-quarters of the world's population live.

The scarcity of qualified personnel in the field of sanitation remains acute, and the highest priority is being given to the training of sanitary engineers and related personnel.

Training and education were at the very core of the efforts made by the Organization to assist countries to meet the many health needs of mothers and children, especially in rural areas. International teams, working side-by-side with national counterpart staff in twenty countries during the year, were principally engaged in training activities.

# RESEARCH COUNCIL OF ALBERTA

## REPORT FOR 1954

THE thirty-fifth annual report of the Research Council of Alberta* outlines the work of the Council for 1954, a year in which the geological research programme was enlarged to meet an increasing demand for basic geological information, and increased effort was placed on natural gas research. The construction of the Council's building was commenced; with its completion most of the scientific work will be consolidated under one roof, and more specialized testing and investigational work on behalf of industry will also be possible. The programme of more fundamental research on coal, initiated in 1953 with the object of advancing the knowledge of the constitution and behaviour of coal, was continued; an extended survey of the colloidal structure of typical Alberta coals by means of heat-of-wetting measurements was virtually completed and has confirmed the existence of a catenary type of relation between accessible inner surface and coal rank. More detailed measurements have been made of the sorption of oxygen by coal at − 25° to − 40° C. and considerable progress was made in studies of the effect of an ultrasonic field on the solubility of coal in such solvents as methyl alcohol. Laboratory studies of the low-temperature carbonization of Alberta coals indicate the possibility of modifying profoundly the course of carbonization by means of cracking catalysts, and studies have also been made on the following topics: the constitution of humic acids derived from coal and of the humic acid content of low-grade Alberta coals; techniques for concentrating spores from shales and various kinds of coal with the view of cataloguing plant microfossils of the uppermost Cretaceous and lowermost Tertiary formations of central Alberta; the suppression of surface dust on bituminous coal briquettes; the grindability of sub-bituminous coals.

In the work on petroleum, the study of trace metals (particularly vanadium, nickel and iron) in crude oils was extended to include oils from other oil horizons of the Western plains, and more recently to include magnesium, since the occurrence of magnesium in crude oils appears to be related to the presence of chlorophyll in the living material from which the crude oils are formed. Determinations of sulphur in these crude oils indicate no close relation between the sulphur content of a crude oil and its trace-metals content. A study of the settling characteristics of solid particles in emulsions of water in heavy oils showed that the presence of water retarded appreciably the settling characteristics of solid particles. Certain 'heavy oil' fractions appear to have special merit as a briquette binder and for preparing metallurgical coke, and attempts were also being made to separate the sulphur compounds present in 'heavy oils' from Athabasca oil-sands.

The research programme on natural gas has included the construction of a new furnace for studies on the formation of carbon black, and work on the partial oxidation of *n*-butane continued. A complete section of the McMurray oil-sands formation has been examined for oil saturation, grain-size distribution and heavy minerals analysis, and a Pleistocene research and survey programme initiated in the Coronation district. Mineralogical analyses of a number of clays from south-western and west-central Alberta were completed, and clay research was extended to include the Bearpaw formation.

The Council's part of the Alberta Soil Survey, a joint effort with the Dominion Experimental Farms Service and the University, included a reconnaissance survey of about eight hundred thousand acres, and an exploratory survey of four hundred thousand acres in the Grande Prairie and Beaverlodge areas. Despite exceptionally heavy rainfall, irrigation research in the Youngstown area showed beneficial effects from irrigation in relation to certain soil amendments and cultural practices, while the sub-surface drilling operations initiated during the year are proving of value in soil surveys and irrigation research as well as in geological studies on clays and other non-metallic mineral deposits. Laboratory results in the Highway Research programme indicate that the chrome–lignin gel is as effective in reducing frost heaving as the plain lignosol, and may be more effective provided it is properly dispersed in the soil.

The Biological Cycles project shows that the ten-year cycle is now at what is assumed to be its complete ebb, with signs of recovery in places. In the Department of Animal Science at the University, the Council sponsored investigations of the factors affecting the percentage hatch of turkey eggs and of methods of improving the quality and yield of grass silage. Solar ultra-violet radiation measurements were continued, and an Advisory Committee on Industrial Pollution was constituted to provide technical guidance at an early stage in Alberta's industrial development in the hope of avoiding difficulties now encountered in older industrial regions. The committee appointed to study the fluoridation of public water supplies has now reported. At the end of the Council's report the usual list of publications is appended.

# THEORY OF ADHESION

IT may be claimed that progress on the practical or empirical side of adhesion and adhesives is more rapid and even spectacular than on the theoretical; but, whether this is so or not, the fact remains that, in the field of production engineering and in other directions, rapid advance has been recorded, especially during the past year or two, some of the most remarkable results being achieved in aircraft design and manufacture. A detailed description of the purely practical application of adhesives to aircraft production is given by Mr. George Epstein, of the Aerophysics Department, North American Aviation, Inc., in his book, "The Adhesive Bonding of Metal" (New York: Reinhold, 1954), and, in lesser detail, in his contribution to the Basic Materials Conference, held in Chicago in May 1954[1].

Several contributions have recently been made to adhesion theory by workers in France, Germany and the U.S.S.R. By way of introduction to these, reference should perhaps be made to the interesting chapter by A. J. Staverman on molecular forces in relation to adhesion which is published in the book by de Bruyne and Houwink on "Adhesion and Adhesives" (1951). This chapter deals at some length with the molecular aspects, to which attention hitherto has been mainly directed, including different kinds of molecular forces and the significance of molecule size, polarity, etc., in connexion with both cohesion and adhesion. It is rightly concluded that much yet remains to be done before we have a complete understanding of the nature of adhesion based on molecular characteristics.

J. Remond[2] includes a discussion of the problem of adhesion (*collage*) and endeavours to elucidate its scientific foundations. In his view, these are to be found entirely in the inter-atomic or inter-molecular forces which account for both the cohesion within matter itself and for its adhesion to another body. These forces have a common origin, are of an electrical kind, and are to-day divided into primary and secondary. It has been realized for some time that the electrical aspects, or in other words, molecular polarity, are of fundamental importance; but as will be seen later in this article when recent Russian ideas on the subject are considered, a new electrical conception of adhesion has been evolved. Meantime, the close similarity between cohesion and adhesion as indicated by Remond is of considerable interest. This has been stated elsewhere in another form: any adhesion theory which attempts to correlate thermodynamic factors, electrical charge factors, or molecular structure factors with the observed strength of an adhesive joint is, in effect, providing a theory of the strength of solids—cohesion—in terms of these factors. In this connexion, of course, one has to remember that the adhesive bond may sometimes be stronger than that of cohesion—for example, where the assembly breaks down, not at the adhesive joint but by fracture within one or other of the parts joined. One has to note, also, at least two kinds of adhesive fracture: where the adhesive film 'tears away' from one or both the joined surfaces, and where the film itself splits into separate laminæ.
